The evidence given by Mr. Adams regarding relationship between the river and conditions of sub-soil and level of subsoil water as affecting the Farleigh sources of water supply is of much interest. The facts adduced by him on this point, if they cannot be held as definitely proving the relationship he seeks to establish, are nevertheless suggestive of causative connexion between these factors and the outbreak of typhoid fever. His contention, however, that these conditions were also related with prevalence of "premonitory" diarrhoea in the borough of Maidstone shortly before the outbreak of fever, is based on less sufficient evidence. Indeed, the data upon which this contention is based are too incomplete to warrant acceptance of the belief that the fever outbreak was actually preceded by prevalence of diarrhoea of a sort differing materially from the seasonal diarrhoea usual in towns during the summer. While this is so, yet the evidence, as far as it went, suggests that there had been a special incidence of diarrhoea on the areas within the borough of Maidstone supplied by Farleigh water, and that, in the opinion of at least some medical men in this town, the diarrhoea was of unusual character. These statements, coupled with there having been, mainly in August and September, an unusual prevalence of colitis in the asylum, render it to be regretted that fuller evidence should not have been available on this subject."

In this expression of regret we most cordially join, but unfortunately subsoil water investigations are difficult to make, and are rarely carried out in a completely satisfactory manner. It is extraordinary that PETTENKOFER'S great work on this subject has not led to more important results.

Further on in the report we find the following. "We are of opinion that many of the cases of typhoid fever in the borough of Maidstone were due to defects of drainage and sewerage, with consequent pollution of the soil underlying the town. The responsibility for the existence of these unsanitary conditions lies with the Town Council, whose duty it was to take steps that would lead to effective remedy of these defects. This duty they have in large measure neglected, notwithstanding that for many years the Medical Officer of Health has in the plainest language repeatedly warned them of the risks to which the health of the inhabitants of the borough was exposed by the continuance of these unsanitary conditions. The Town Council, therefore, cannot plead ignorance of the facts by way of excuse for their failure of duty in this respect—a failure of duty which has led to the gravest consequences."

From all this it appears that the importance of the soil, saturated and contaminated, is becoming more and more recognised and appreciated as a potent factor in the etiology of typhoid fever.

THE PLAGUE FIASCO IN CALCUTTA.

At the time of writing Calcutta has been for seventeen days free from fresh cases of plague, so that it is highly probable that before these words appear in print, the curtain will at length have been rung down on the doleful fiasco that has been played in the city and has run its weary course for the last six months.

We really are quite unable to decide who is most to be congratulated on the result, the Supreme Government which with its host of followers and idlers will now be able to enjoy its usual season of festivity and levity in the city, the Municipality with a heavy weight of care and responsibility removed from its shoulders, the merchants and traders with brightened prospects of increasing business, the native population relieved from the fears of segregation and inoculation, the special plague officials and imported nurses who are drawing their salaries for doing nothing, the taxpayers who at length see a prospect of their valuable services being dispensed with, or finally, we ourselves for having consistently from the beginning scouted the idea that plague had ever been really present at all.

The false prophets have been discomfited, and henceforth their best refuge will be in silence. Where now are the ugly forebodings, the gloomy brows, the mysterious head shakes and oft repeated warnings? What has become of the terrible epidemic so often prophesied, so wonderfully postponed? It was to have come with the rains, but it did not! The end of the rains was to have seen it lighting up, by the beginning of the cold weather its ravages were to have been enormous! And yet *mirabilia dicta*, in spite of all these soothsayers' fancies, here we are in the middle of October, and instead of the plague increasing by leaps and bounds, it has disappointed all its sponsors and has chosen to die a natural death.

That plague, if plague it was, should have manifested itself in Calcutta just at the beginning of the season, that we have always been told, was most unfavourable to it, and that then it should die out just at the beginning of the season supposed to be most favourable to it, is such a very curious concatenation of events, that we must really ask to be pardoned if we cannot accept it all without some slight demur.

We have had a good deal of talk mostly in the lay press, (which in India is peculiar for the knowledge it professes to have of medical matters), of one season being favourable and another unfavourable, of the plague only flourishing in the cold weather and dying out in the hot, and other nonsense of the same kind, for which only the flimsiest evidence can be produced. We have been told a good deal from time to time of the habits of plague by those who set up to know, or were supposed to know, but the statements made have mostly appeared to us reckless, without any solid foundation, and curiously suited to the exigencies of the hour and the necessities of the situation.

What we now want to know is, why has the plague, we cannot call it the epidemic of plague, died out? Why has it behaved so differently in Calcutta to what it has done in other places? Why has Calcutta not followed in the steps of Bombay?

There are persons that will not be inclined to answer satisfactorily, yet earnestly desire to know they must be in the near future with the Plague Commission, and often under the shadow of their swordship in their own backs.

If there is something about Calcutta that is particularly obnoxious to the plague, by all means let us know it, it will be an important addition to our knowledge. It can hardly be said that the city is too clean and its sanitation too perfect for the health of the plague germs; that the population is too well housed; that there is not sufficient overcrowding, or that the cleansing department does its work too thoroughly for even a plague bacillus to escape its notice.

No certainly none of these things can be said! And ignorant as we are of the means by which the supposed plague effected its entry, we will in the end probably be more so, as to the cause of its exit.

The disease to which the name of plague has been given, has been in Calcutta for six months, not confined to one special locality, but spread extensively throughout the city. Yet it has not been carried into the adjoining districts, though the restrictions placed upon the movements of the population have been almost nil. With the exception of Bagdal, where we hear some suspected cases occurred, not a single case has been brought to light.

The year has so far been a healthy one and for this we must be thankful, but as for the nature of the disease that has been so carefully watched, guarded, and tabulated, we are unfortunately, but little the wiser.

As far as clinical evidence goes, there is plenty of it to show that this special disease, a form of malignant typho-malarial fever with or without glandular affections, it has been known and has prevailed in Calcutta, for years.

As far as bacteriological evidence goes, and we gather that a very limited number of bacteriological examinations have been made, the plague bacillus has been found. We have no reason to doubt the accuracy of the results obtained, nor do we see sufficient reason to doubt the accuracy of the results obtained by Dr. SIMPSON in 1896. We will suppose that the bacillus was found on both occasions, and draw the conclusion that Calcutta has now safely passed through its second visitation of plague.

Assuming however that the true bacillus of plague was present in the majority of the cases, it must be admitted that it is extremely difficult to account in any reasonable manner for the course taken by the disease.

Is Calcutta to stand forth as the one grand, solitary instance of an overcrowded filthy oriental city which has been invaded by plague, and yet has escaped unscathed?

There is on the other hand no difficulty in assimilating the course of events to the clinical evidence, which points to an endemic disease, subject like all endemic diseases, to seasonal fluctuations and cyclical variations.

THE SEVENTEENTH MEETING OF THE INDIAN MEDICAL ASSOCIATION.

In accordance with Notices issued by command of the President, the Seventeenth Meeting of the Council of the Indian Medical Association was held at his Office, 55, Esplanade Street, Calcutta, on Tuesday, the 4th October 1900, at 6 P.M. An adjourned session of the same Meeting was held on Wednesday, the 12th October 1900 at 6 P.M.

Present :—Dr. LAL MADHAR MOOKERJEE, Rai Bahadur, (President in the Chair), Dr. E. W. CHAMBERS, (Vice-President), Drs. H. W. JONES, K. G. SINGAR, H. C. HONGKING, RAKHAL DAS GHOSH and JAMES R. WALLACE.

Business :—(1) The Notice calling the Meeting having been read, the Minutes of the last regular Meeting of the Council were read and confirmed.

(2) The Secretary presented the names of twenty-one new members who had applied for admission to the Association. They were duly elected.

(3) THE INDIAN MEDICAL ASSOCIATION PROVIDENT FUND.

The Secretary reported that 223 members had already joined the Association Provident Fund, irrespective of a large number who would become members as soon as Surgeon-Captain WADE made over the statement of accounts and moneys belonging to the Warrent Medical Officers' Provident Fund. The Secretary represented that as three or four subscribing members of the Association Provident Fund had already died, it became necessary to allow their claimants to receive some benefit from the Fund, and that this could only be done with the sanction of the Council. He therefore requested that permission be granted to float and work the Fund at once, in spite of the fact that the full complement of 500 members had not yet been attained.

Resolved :—That the Indian Medical Association Provident Fund be started forthwith, and that payments be made now and henceforward to claimants on the Fund, on proof of claim in accordance with the Rules of the Fund.

(4) MEDICAL AND SANITARY ASPECTS OF THE NEW MUNICIPAL BILL.

After a full discussion of this subject it was resolved that the Secretary do prepare a statement embracing the suggested alterations in the new Bill in connection with the Medical and Sanitary aspects of the same, and that such statement be forwarded to the authorities.

(5) GOVERNMENT DOCTORS AND PRIVATE PRACTICE.

The letter from the Government of India in regard to this matter having been read, it was resolved that the Secretary of State for India be now approached in view to having the unjust and iniquitous monopoly of private practice by State-paid doctors removed. The Secretary was desired to prepare a statement in connection with this matter, setting forth the whole official correspondence in regard to the same.

(6) MEDICAL PROFESSIONAL AND HOSPITAL APPOINTMENTS IN INDIA.

In view of certain Medical and Surgical appointments recently made in the additional and hospital staff of local medical colleges an important discussion was raised in the Council. After the consideration of the subject in all its phases, it was

Resolved :—That in view of the vital importance of the fact that all medical schools in Great Britain and Ireland

In the British Colonies and in the Dependencies of the British Empire, where teaching certificates and diplomas are accepted by the General Council of Medical Education of Great Britain, are compelled to recognise certain fixed academic qualifications for all their teachers, and that these conditions are binding on the medical educational agencies of the Indian Empire, and that any violation of these conditions is likely to endanger the acceptance of the certificates and diplomas of Government Medical Schools in India, and thus inflict an irreparable injury on locally trained medical students and practitioners who resort to Great Britain for degrees and diplomas, the Council of the Indian Medical Association desires to express its emphatic protest against the violation of the conditions which govern the appointment of teachers in the Medical Colleges and Schools of India which are recognised by the General Medical Council of Great Britain.

II. That the Council acting under a sense of deep concern and anxiety in the interests of medical students in Indian Colleges, which are entirely under the control of the Government of this country, desires to express its alarm at certain recent appointments in the local medical colleges, in which the incumbents do not fulfil the qualification demands of the General Council of Medical Education of Great Britain.

III. That in view of the damaging influence of such questionable appointments, not alone on the reputation of Indian Medical Colleges themselves, but on their alumni both in this country and abroad, the Council desires to express the earnest hope that appointments to the medical educational institutions and hospitals of India under the control of Government, shall under no circumstances be made in violation of the conditions which are compulsory for all incumbents who aspire to the important positions of teachers and consulting physicians and surgeons to such institutions.

IV. That in view of the important fact that the positions of Consulting Physicians and Consulting Surgeons to Educational Hospitals under the present circumstances of medical and surgical practice in India, confer on these offices a distinguished prestige, which of necessity commands the confidence of the public, both lay and professional, as consultants, it is incumbent on the Government in nominations to such offices, to be guided absolutely by the requisite academic qualifications, which not only are demanded by the regulations of the highest medical authority of the British Empire in matters of medical education, but by which the public interests in consultative practice can alone be met efficiently, and with that needful security to which danger to life in serious conditions of disease demand.

V. That in view of immediate action being taken by the authorities in connection with these Resolutions, a copy of the same be forwarded to the Chief Secretaries of the Supreme and Provincial Governments, to the Director-General of the Indian Medical Service, to the Inspectors-General of Civil Hospitals, to the Directors of Public Instruction as well as to the Presidents of the Medical College Councils of the various medical colleges controlled by the State in India.

With the passing of the above resolutions and a vote of thanks to the Chair, the meeting was closed.

COMMENTS AND NEWS.

**NO MORE OFFICIAL PLAGUE IN CALCUTTA.
THE GOVERNOR'S DECLARATION THAT
THE CITY IS FREE OFFICIAL
PLAGUE MANUFACTORY
SHALL BE KEPT
GOING.**

THE following *Calcutta Gazette Extraordinary* has been issued:—

It is hereby notified for general information that Calcutta is free from plague, and that all inspections of, and restrictions regarding, travellers from Calcutta have been withdrawn.—E. N. BAKER, Officiating Secretary to the Government of Bengal.

RESOLUTION.

The Lieutenant-Governor has the great pleasure of announcing this day that Calcutta is now free from the infection of bubonic plague, no fresh case of or death from that disease having occurred for ten days since the last reported case was discharged cured from hospital on the 23rd ultimo. By a Notification No. 6036 of this date, all inspections of, and restrictions on, travellers proceeding from Calcutta have been withdrawn, and detailed orders to this effect have been issued to the authorities concerned. By Notification No. 14 of this date, the Lieutenant-Governor has also withdrawn those provisions of Plague Regulation No. 14, dated 7th June, 1898, which require that the passengers and crew of all vessels leaving Calcutta for any port out of India, or for Rangoon, Aden, or the ports of the Madras Presidency, shall be medically examined *on shore* at the time of embarkation. The passengers and crew of such vessels will now be subject to medical examination either on board or on shore, as may be found convenient, and provision has also been made, in the case of passengers, for the acceptance of a certificate signed by a Commissioned Medical Officer, in lieu of such examination, as was the rule in force, under Plague Regulation No. 3 of 17th August, 1897. By these orders both the foreign trade of the port and the inhabitants of Calcutta who have occasion to travel, will be relieved from the restrictions which the outbreak of plague in April last, now happily at an end, rendered it necessary to impose.

While, however, the Lieutenant-Governor has with the satisfaction he shares with the whole community, taken the earliest opportunity to declare that Calcutta is free from the infection of plague, he feels it incumbent upon him to utter a word of warning. Though the town is free from the immediate presence of plague, it is too soon to assume that the danger is wholly past. The beginning of the cold season is now at hand, and the experience gained elsewhere shows that this season is liable to be accompanied by renewed activity of the disease. While, therefore, he earnestly hopes and believes that the plague, which had obtained but little hold on Calcutta and has now quitted the city, has gone for good, it is nevertheless of the utmost importance that there shall be no relaxation of the precautions which are being taken to prevent an outbreak of the disease and to detect cases promptly if they should occur. The Lieutenant-Governor trusts that the war, caste and family hospitals which, with such praiseworthy generosity and public spirit have been opened by many sections of the public and by private individuals, will be maintained in working order for some months to come; and he particularly desires that the special efforts which have been made by the Corporation to make the town clean and keep it so may in no respect be relaxed. It

would be the most direct to meet the needs of the hospitals have been tried, and that sometimes they have not required; or to improve, because the climate has made good its hold upon the town, that the most efficient sanitary measures taken during the past few years have been unnecessary. The Government, however, relies, as heretofore, on the public mind, and chiefly on operation of all notions of the community to secure the relaxation of the vigilance which has thus far been attended by success, so that if unhappily the disease should again present itself at our doors, it may find us still unprepared to meet it.

NATURE AND SIGNIFICANCE OF LEUCOCYTOSIS.

Dr. NATHAN STIRLING, Lecturer on Pathological Bacteriology, Edinburgh University, opened the discussion on this subject at the recent meeting of the British Medical Association, in these words: "The subject of the discussion which I have the honour of opening is at once one of the most important in modern pathology, and has also a most important bearing on clinical diagnosis and prognosis."

After alluding to the very extensive nature of the questions opened up he said:—"I shall take as the main subject of my remarks the nature of leucocytosis as a process in general pathology. What is the fundamental change on which the leucocytosis depends, and what is its standing in relation to the question of tissue reaction?"

The term leucocytosis may be applied to any condition in which there is an excess of leucocytes over the normal whether in the tissues, or part the vascular system; local, or general leucocytosis.

"The general facts are well known—that in many acute inflammatory conditions, occurring naturally or experimentally produced, such as pneumonia, erysipelas, etc., and especially in suppurative conditions, the number of leucocytes in the circulating blood may be two or three-fold the normal, or even more. Further, a similar condition may be said to be produced by the introduction into the body of various chemical substances, of which the most important classes may be said to be (a) bacterial products, especially the so-called bacterial poisons; (b) extracts of various organs or tissues rich in cells, such as spleen, bone-marrow, etc.; (c) a great variety of definite organic compounds—for example,—peptone, curare, nucleic acid, etc."

It has been shown by recent researches, especially by those of GOLDSCHMIDT and JACOB, with which the author's researches agree, that this condition of leucocytosis is real, that the total number of the leucocytes circulating in the blood is increased.

"There are two points which also must be kept in view.

(1) The variety of leucocyte in excess in these conditions is almost exclusively the finely granular (oxyphile or neutrophile), actively ameboid leucocyte, with polymorphous nucleus (2) the enormous rapidity with which the leucocyte increase occurs—namely, a doubling or more of the normal number in a few hours."

ORIGIN OF THE FINELY GRANULAR LEUCOCYTES

Dr. MUIR briefly described the varieties of leucocytes met with in man and discussed their distribution, and gave reasons for the opinion he had formed, that the finely granular, polymorphonuclear leucocytes "are formed chiefly, if not entirely, from the bone-marrow and enter the blood-stream in their fully formed condition."

LEUCOCYTOSIS IN INFLAMMATORY CONDITIONS.

There is no evidence to show that these polymorphonuclear leucocytes multiply either in the tissues or in the blood, and an important question arises, namely, Are any important changes found in the bone-marrow when there is an increased production of this form of cell?

The author's researches show that there are changes in the bone-marrow in such conditions, and he says:—"I find that there is a marked increase in the number of the finely granular leucocytes, which is readily recognizable. The changes consist in the rapid absorption of the fat of the marrow and a consequent hyperplasia of cells; and further, the important point is that the cells increased in number are the large finely granular cells which may be called 'finely granular leucocytes,' and which are the source of the finely granular leucocytes. The number of mitotic figures present shows that these cells are undergoing rapid multiplication. The eosinophilic eosinophilic cells are relatively and in many cases absolutely diminished. Erythroblasts or nucleated red corpuscles are also much diminished. The giant cells may undergo degenerative change and in great part disappear. (These cells do not contain granules, and are probably derived from the larger hyaline cells.) The marrow in such a condition presents a striking deviation from normal, and the change may be said to be of a corresponding nature to what occurs in the erythroblasts after hæmorrhage (great increase in their number and increase in the mitotic figures). If we call the latter the "erythroblastic" type of marrow, then we may call that which I have described the "leucoblastic" type of marrow. This fact appears to me to throw light on the whole subject. If we consider the finely granular cells as a class—may in a case of suppuration—we find (a) locally an enormous number of finely granular leucocytes (pus corpuscles); (b) in the blood a great increase in the number of the same cells; and (c) in the marrow a great increase in the cells from which these leucocytes are derived."

The phenomena of leucocytosis are explained by the action of chemotactic substances, such as bacterial products. In some cases the quantity may only be sufficient to act locally, but when in larger quantities, these substances are absorbed into the blood-stream and produce general leucocytosis.

In interpreting the phenomena we may then say: (1) That the local leucocytosis is a most important means of defence; (2) that the proliferative changes in the bone-marrow are the means by which the leucocytes concerned may be supplied in large numbers at any given place of need; (3) that the leucocytosis in the blood is an indication at least that this supply is being maintained. We may also mention that the vascular arrangements in the marrow are such as, on the one hand, to permit a ready action upon its cells of chemotactic substances circulating in the blood, and, on the other hand, to allow a free and rapid passage of the cells into the blood.

It is to be noted that chemical substances must be the means by which a general leucocytosis is brought about, and therefore it is not surprising that it can be produced when there is no local inflammatory change. Whether in such a case the leucocytosis really acts as a means of defence by combining with toxins in the blood, for example, in the leucocytosis following injection of diphtheria toxin, must still be considered an open question.

RELATIONS OF THE FINELY GRANULAR AND HYALINE LEUCOCYTES.

I have said that in view of their chief sites of multiplication the great majority of leucocytes fall into two series, one including the lymphocytes and hyaline cells which multiply by mitotic division in lymphoid tissue, lymphoid glands, malpighian patches of spleen, solitary glands, etc., the other including the finely granular leucocytes and the finely granular leucoblasts of the bone-marrow and possibly the eosinophilic series.

Now if we consider these two series of leucocytes as described, and suppose an external influence to act on either, we have an explanation of the two types of leucocytosis.

It is well known that the leucocytes are the most numerous of the corpuscles, and it may be of the opinion that in the same way we have an increase in the number of leucocytes (narrow cells.)

LEUCOPENIA.

A diminution of the number of leucocytes may occur with comparatively rapidity in inflammatory or infective conditions. The diminution is chiefly on the part of the finely granular polymorphonuclear leucocytes. Leucopenia may be due to a number of causes, for instance, in severe septicæmia and toxic conditions an enormous leucocyte degeneration and destruction can be traced in the spleen and to a less extent in the bone marrow, and in certain circumstances there is great leucocyte accumulation associated with phagocytosis in these situations.

It is to be observed that in many cases the conditions determining the leucopenia are of an unfavourable kind, whether they be exos of toxic substances in the blood, exos of leucocyte emigration due to rapid inflammatory spread, rapid leucocyte destruction, etc. It is essential that where there is leucopenia the circumstances that bring it about should be accurately ascertained.

Leucopenia exists in several chronic conditions, as, pernicious anæmia, some cases of chlorosis and anæmia with enlargement of the spleen. Here again the diminution is chiefly on the part of the polymorphonuclear leucocytes, and this association with defective blood formation or with alterations in the function of the bone-marrow is worthy of note.

In the discussion which followed Dr. MUIR's observations, Dr. EDMONSTON CHARLES remarked on the absence of polymorphonuclear leucocytes in Malta fever, and thought that this might assist in its differential diagnosis from typhoid and other fevers.

GROUNDLESS FEAR OF LIGHTNING.

We take the following from the *Scientific American* :—"A current news item given the result of an investigation carried out by Dr. G. STANLEY HALL, president of Clark University, on the things that most excite fear in people. Of the 298 classes of objects of fear to which 1,707 persons confessed, thunder and lightning lead all the rest, although in certain localities, as, for instance, those subject to cyclones, etc., the fear of the latter predominates. It may be accepted as probably true that thunderstorms constitute the most pronounced source of fear with the majority of people, due, no doubt, to the always impressive and not infrequently overpowering nature of the phenomenon. But is there any justification in fact for this fear so far as fatal results are concerned?

We believe there is not, but on the contrary, that many other causes which barely have a place in Dr. HALL's list are infinitely more entitled to the distinction as fear producers than lightning. As proof of this we may cite statistics of the United States Weather Bureau. These show that for the five years 1890-98 the deaths from lightning numbered 784, or an average of 156 a year. Again, H. F. KENTZER, of St. Louis, found from the record of nearly 200 newspapers that for the five years 1888-88 there were 1,080 deaths caused by lightning, or an average of 216 a year. We doubt whether of the number of deaths classed as "accidental" in the whole United States, any two groups can show so small a number. In New York alone over 200 people are drowned every year, with nearly 100 are burned or scalded to death, and close upon 500 persons meet their end by falls of one kind or another. Considering the record of 200 lightning fatalities in the same country with the above records

for New York alone, with the other causes of 2,000 accidental deaths for every year, it is not surprising to find in the popular fear of lightning, there is a certain, an inherited superstition.

But there is still another point in connection with the matter which ought to be particularly comforting to city dwellers, albeit country dwellers may not be affected to the same extent, and that is, that statistics show that the risk of lightning is five times greater in the country than in the city. The cause of this immunity of city dwellers is rather to seek. It is doubtless due to the predominance of metal roofs, the well-grounded water pipes in houses, and probably as much as anything to the protective network of overhead electric wires of all kinds. The popular belief that a stroke of lightning is invariably fatal is also not borne out by facts. Indeed, one record specially devoted to this feature during the year of 112 persons struck, only 74 were killed. Taking it all in all, there seems to be no more groundless superstition than that of lightning. Indeed, if one can go by statistics, the risk of meeting death by a horse kick in New York is over 50 per cent. greater than that of death by lightning.

Yet with all the weight of statistics against its dogmatism, lightning will probably continue to scare people as heretofore. Perhaps, after all, there may be a more direct cause than the mere psychological one usually ascribed to it, and that is the fact that many people of nervous temperament are affected hours before the approach of a thunderstorm and thus rendered particularly powerless to stand the strain which more or less affects the most phlegmatic natures during a disturbance in the heavens."

INDIAN MEDICAL SERVICE REFORM.

THE following is the reply of the Government of India to the Memorial forwarded on 24th July 1898, to the Secretary of State for India on the subject of the separation of the Civil from the Military branch of the Indian Medical Service, in pursuance of the Resolution passed at a Public Meeting of the Bombay Presidency Association, held on 18th April 1896, under the presidency of the Hon. Mr. PHEROZMEH M. MEHTA :—

No. 5386 of 1898. GENERAL DEPARTMENT.

Bombay Castle 27th September 1898.

To the Honorable Mr. PHEROZMEH M. MEHTA, C. I. S., M.A., Barrister-at-Law.

Sir,—In continuation of the letter from this Government No. 3593 of the 14th August 1896, I am directed to inform you that the Memorial has been considered by the Government of India. Their views which are concerned in by the Secretary of State are as follows :—

Many of the statements contained in the Memorial have been demonstrated to be inaccurate, so the Government of India considered more particularly two of the main arguments used by the Memorialists in favor of the change advocated. These were (1) that the present system has resulted in inefficiency in the conduct of the work of the higher medical appointments, and (2) that the proposal of the Memorialists—of which the main outline was that there should be in India a separate Army Medical Service and a separate Civil Medical Service entirely independent of one another—would result in economy.

As to the first contention, the Government of India are of opinion that the Civil work of the Indian Medical Service has been very well performed, that appointments to special duties in the higher branches have been made with special reference to the qualifications of the officers selected, and that the Government have no reason to be dissatisfied with

the manner in which the selected officers have carried out their duties. With regard to the suggestion that the method of filling the Civil Medical Service independently of the Army Medical Service would result in economy, the Government of India observe that the scheme sketched out in paragraph 15 of the Memorial is too vague to lend itself to discussion and that they do not feel justified in entertaining a proposal to subvert entirely the system on which at present both the Army and Civil Medical Departments are officered, without having some well-considered alternative to suggest. This was not supplied in the Memorial, which the Government of India therefore regard merely as an additional indication of the need for placing on a better footing that portion of the Medical Service which is recruited from among the medical students trained in this country. The Government of India are confident that the proposals since placed before the Secretary of State (which are detailed in the Home Department Resolution No. 1140-50, dated the 22nd August 1904 which has been published in the *Government Gazette*) will go far to satisfy the legitimate aspirations of the students of medicine in India who elect to enter Government service.

I have the honor to be, Sir, your most obedient Servant.

B. E. STEWART, Acting Secretary to Government.

DO WOMEN PERFORM ILLEGAL OPERATIONS ON THEMSELVES!

Says the *Medical Times & Hospital Gazette*:—"To many doctors, the idea of an unskilled woman being guilty of an attempt to perform an illegal operation on herself indicates such an amount of ludicrous folly as to appear almost incredible. In view, however, of the prominence which "illegal operations" are enjoying at present, and the circumstances attending some of them, it becomes important to question as to whether or not, the presence of a perforated wound into the peritoneum, through, or in the vicinity of the uterus, necessarily implies a second person as operator. It is very difficult to obtain reliable evidence on such a point, but the evidence to be had leads to the belief that women not unfrequently attempt to procure abortion for themselves by illegal operations. For such purpose they use such dangerous implements as bonnet pins, and the like, and the ease with which they thus provoke internal hemorrhage acts as an encouragement to them to persevere in their efforts. The sensitiveness of the uterus and upper part of the vagina is not at all great, and it is by no means unlikely that a resolute woman might endure the pain self-inflicted in producing a perforated wound. We should be glad if our readers would furnish us in confidence with cases of the kind which have come under their observation. For a woman to operate thus on herself with success is probably rare, but cases seem to occur where this does happen. Probably the woman has some little knowledge, when she operates successfully."

A MEDICAL ENGINEER.

Two poor to himself to meet his craving for ease and luxury, Count ORMOND so cleverly feigned serious illness that he has for more than a year puzzled and deluded the smartest doctors and thus enjoyed the benefits of every hospital in Chicago where he has for weeks together, been tenderly nursed and fed on delicacies. Being able to raise his temperature to 103° or 104° F and accelerate his pulse to 120 or 130 beats per minute, his favorite plan was to simulate a dangerous fever; though he could develop all the symptoms of a wide range of illnesses in such a way as to completely deceive the doctors. One trick of his to elicit the sympathy of the nurses was to be found in the streets in a

dying (?) condition, as the result of some fatal ailment to being the victim of unrequited affection; but he was soon bowled out and had to seek new fields for the exercise of his novel arts; as he was not so content to the apex of the alleged, hard-hearted lady love as to his scheme of impersonation.

THE DOCTOR AND DOCTORS.

THE following verses on medicine as a profession, by EASTON WATSON's appeared in a recent number of the *Scottsman* and should be read by those who sometimes take up medicine as a method of earning a livelihood:-

When a jolly young fellow obtains his degree,
His heart is expanded with gladness and glee,
And he thinks his life mapped out as plain as can be
Since he got himself dubbed as a doctor.

But after a little he alters his life,
The gingerbread loses its glitter and gilt,
And he thinks he will take the Queen's bob and a hit
To get rid of this job as a doctor.

He must travel the country side, uphill and down;
In the winter he's blue, in the summer nut-brown;
If he's tired from the sole of his foot to his crown,
It is only his luck as a doctor.

For to do a good deed loses half its delight.
If he gets out of bed in the dead of the night
To patch up a pauper who's been in a fight
And requiring the aid of a doctor.

So all you young fellows, where'er you may be,
The height of whose wish is to get a degree,
Just chuck it whenever these verses you see,
For they come from the pen of a doctor.

DEFINITIONS OF THE "PATHIES."

The *Clinique* says that a jolly correspondent quotes and forwards the following definitions:

Christian Science—Suggestion plus absurdity.

Divine Healing— " " faith in God's mercy.

Osteopathy— " " massage.

Hydropathy— " " water.

Metaphysical Healing— " " fog.

Hypnotism— " " sleep.

Spiritualism is somnambulism, and

Theosophy is an intellectual pleasantry.

To this we might add that there are ill-natured people who would say that homeopathy is suggestion in material, plus drugs in infinitesimal doses. There are even members of the "regular" profession, we believe, who would seem to hold all medicine to be principally suggestion. At least, we have heard of a celebrated hospital physician and teacher in London, who, at a clinical lecture, told his students to pay all their attention to diagnosis and prognosis. After an exhaustive dissertation on a case, he was leaving the bedside without prescribing any treatment, when the house physician asked what he should give the patient. "Oh," said the physician, "a hopeful prognosis and anything else you please."

PROFESSIONAL SECRETS.

MADE known to a doctor by a patient in the course of consultation should be preserved inviolate, is what our esteemed contemporary the *Medical Times and Hospital Gazette* emphasises, and we agree with him that it would be wrong in principle and ruinous in practice to give the public information of every crime (or rather what the law calls crime) which comes under medical notice professionally; as there are many instances where under the seal of confidence the doctor learns of matters that may be an offence, but should a patient betray a positively homicidal or suicidal tendency or at times be a violent maniac needing restraint or

of the law, and the law is not to be proper protection for the public health, it is the doctor's burden to see to it that the law is not broken by anyone who is not a doctor. The law is not to be broken, however, for law and as the law is to be broken, we must admit those who deal in it at all risks of being punished for it; but we must not be so stupid as to think a doctor who deviates from his duty in his patient in this respect, owing to fear of threats by those who administer the law.

AN ASSISTANT SUPERINTENDENT FOR THE HEALTH DEPARTMENT—A PROPOSAL BY THE CALCUTTA HEALTH OFFICER.

THE effectiveness of the Health Department as a whole depends primarily, in my opinion, on the efficiency of the individual officers constituting it. If, for instance, an incompetent Superintendent is appointed, all the Inspectors under him will get slack, or be taught to do things the wrong way, or somehow make a mess of them. The Superintendents come in contact with the Inspectors in a way that I myself cannot. If I went round with an Inspector every morning it would be a month before any individual Inspector got his second lesson. He could certainly not get instruction on more than 12 occasions in a year even if I did nothing else. One of the most important functions then of the Superintendents is to teach the Inspectors and get them into a good method of doing their work. Any man who knows his work and can teach his sub-officers and keep them up to the mark is worth paying for, any one who has not these educational and personal qualifications is not worth his salt. On these grounds I am of opinion that the appointment of Assistant Superintendent should be abolished and a fourth Superintendentship should be made in its place on a salary that would attract suitable men. None of the applicants in any way come up to my standard of what a Superintendent should be. Two of my native Superintendents are good men, considering that they have not had the advantage of the excellent sanitary education that can now be obtained in England, and I have no idea of making a clean sweep of such men. But I think the introduction of one or two highly trained and experienced English certificated men would have a very good effect in improving the class of work turned out by everybody. Such men could also be promoted to fill the office of Chief Superintendent if at any time it fell vacant. I should propose to offer Rs 850 rising by annual increments of Rs. 25 to Rs 450 a month plus a horse-allowance of Rs. 50. I believe that this pay would attract men of the class I propose to employ. I have no doubt that men would be forthcoming if advertised for, as in consequence of a passing reference in the "Sanitary Record", the journal of the Sanitary Inspectors' Association, two such men have written to me by this week's mail, asking for employment (vide letters attached). The proposed pay is not more than has been given to Superintendents, as the Budget of 1895-96 shows that one of the Superintendents was getting Rs. 400 per mensem plus Rs. 50 horse-allowance.

JAW-BREAKERS.

Says the Morning Post—The following is what a fond father wrote to his son as a mild rebuke for the latter's objectionable habit of always, when writing his home "effusions," using jaw-breaking words—

"My dear son,—In promulgating your ecstatic cogitations, of articulating superficial sentimentalities and philosophical or psychological observations, beware of platitudinous generalities. Let your observations possess a clarified coherence, a compacted comprehensibility, a succinct con-

clusionary and comprehensive brevity. Beware of digressions of vacuous garrulity, of the repetition and uninteresting observations. Let your expressions be clear, concise and unpretentious. Your observations have no interest without rhodomontade or rhetorical bombast. Beware of all polysyllabic profundity, pompous prolixity, and verbiage. Speak with confidence and pleasant simplicity, whether obscure or apparent. In other words speak truthfully, naturally, clearly and purely, but do not use big words."

TEN DAYS FREE FROM PLAGUE.

THE attention of the Committee of the Bengal Chamber of Commerce having been drawn to the fact that an erroneous impression prevails that when ten days have expired without a further case of or death from plague, Calcutta may be declared non-infected under Chapter II, Section 3 of the Venice Sanitary Convention, it is intimated that a letter has been received from the Secretary to the Government of Bengal, Financial Department, stating that, under the terms of the Convention the ten days would therefore not expire until the 8th instant. The matter is receiving the close and constant personal attention of H. H. the Lieutenant-Governor, but it rests with the Government of India, and not with the Government of Bengal to issue the notification declaring Calcutta free from infection. Since writing these lines the Government has declared its plague removed.

ACONITE POISONING.

SAYS the Medical Age—The only English case, in which the active principle of aconite has been used as a poison is the case of Dr. LAWSON who poisoned his brother-in-law, PEROX MALCOLM JOHN, to obtain the sum of \$1,500, in which he had a reversionary interest through his wife. The brother-in-law was a youth of eighteen years of age, paralyzed in his lower limbs from long-standing spinal disease. The youth died in less than four hours after taking a gelatin capsule containing some white powder which he was told was sugar. LAWSON was arrested, tried, condemned, and hung. The difficulty of proving the presence of a rare vegetable alkaloid in the body after death was the reason no doubt why LAWSON used aconite as the poison he used.

A BIG FEE.

THE *Hyderabad Chronicle* writes—"We learn that the trouble between Dr. LAWRENCE and Mr. SHAIKH OOMER is regard to the fee payable for the symphysectomy operation performed on the latter's wife, for which a fee of Rs. 2,000 was claimed, has been adjusted. Dr. LAWRENCE having informed Mr. SHAIKH OOMER that he accepted his assurance that he was not able to pay a larger sum than Rs. 800; and that with the sanction of the Resident, he would receive that sum as payment of his fee. Surely Mr. CHAWWORTH will not allow a payment so exorbitant to be accepted by a medical man in the service of the Government of India."

We consider Rs 800 a small fee for such an operation, especially when performed by so eminent a surgeon.

MUNICIPAL NUISANCES IN CALCUTTA.

SAYS Indian Engineering—"There is a more serious nuisance than that of the removal of refuse from town-refuse by rail along the Circular Road of Calcutta. We would invite the attention of the Chairman of the Corporation to the worse than plague, the standing masses of public health, at the Jaan Bazar end of Circular Road, in the midst of a densely populated centre, in close proximity to a large European

[illegible]

CALIFORNIA MEDICAL COLLEGE ANNOUNCEMENT

The recent appointments of Lieut.-Colonel E. D. STURMAY, M. B., as Director of Surgery and of Lt.-Colonel C. F. A. HARRIS, M. D., M. B., as "Professor" of Medicine, have been very fully discussed to the Council of the Indian Medical Association in protest against the nominations of the Government for these two important posts. Of course the Council cannot confirm these two medical officers in their high and important offices without committing a serious and grave breach of the Regulations of the General Medical Council of Great Britain. Our readers will approve of the just and necessary resolutions which are implied in the Resolutions which have been passed at the last meeting of the Association Council and which are fully reported elsewhere in our current issue. We sincerely trust the Government will be properly advised by the medical administration of this country to cancel the very questionable appointment of men to offices which by the dictum of the highest medical authority in the British Empire, they must be pronounced as being unwarranted to fill.

A CLEAN SWEEP.

Our "financial" contemporary *Capital*, which is an undoubted authority on matters Municipal in Calcutta, writes:— "When the Municipal Bill is passed it will be necessary to make a clean sweep from the Chairman downwards if really good results are expected. The present unsatisfactory position is not due to Babudom but to Chairmanship, Vice-Chairmanship, Engineeringdom, Health Officerdom, and all the other "doms" that follow in their train. If the Government really desire that Calcutta shall be properly administered they must see that the executive is thoroughly up to the mark, a thing which it has never been in the past, is not in the present, and we doubt if it ever will be in the future; unless the necessary reforms that we have indicated are carried out."

THE PRACTICE OF REPEATING PRESCRIPTIONS.

A recent decision of the Ministry of Public Worship, of Education, and of Medical Affairs in Germany is of interest. Physicians for internal use in Germany may not be responsible for the patient by an apothecary unless the physician signifies his approval in writing. External remedies, however, may be repeated. Substances prescribed as eye-washes, or those for inhalation, for subcutaneous injection, or for internal and suppositories are by this recent decision classed among internal remedies as regards their repetition, though the regulations as to bottles and labels that hold for external remedies still apply to them.

THE L. M. A. PROVIDENT FUND.

We would invite the attention of subscribers to this Fund, to the advertisement which appears in the Report of the Council, just meeting in this issue. We trust that as the Fund is now opened, all who have held aloof hitherto will join as soon. It will be observed that a few claimants have already as opportunity to reap a small benefit from the Fund. As the benefit to be derived from the Fund depends entirely upon the number of subscribers, we trust medical men and women will use the prudence and the necessity of combination in this important matter of family provision.

CENTRAL PROVINCES RAILWAY WORKS

The principal undertakings of this class in progress during the past financial year were in connection with water-supply, the most important being the improvement of the water supply and drainage of Jubulpore. The question of a water supply for Haveli, which was under consideration, had to be postponed temporarily for want of funds, but good progress was made with the Warden Works, which have been brought to completion.

SECRET

It is very encouraging to find that the suggestion proposed by the *Record* to convert the *Eastern Edition* into a daily paper has *more than 250 subscribers*. The *Record* is anxious to wish to see the *Record* readers of the *Eastern Edition* so constant in their homes. We fully expect that the great majority of the nearly four thousand readers of the *Record* will withhold his glad acceptance of the proposed change. We still wait however for a further response from our readers. A few are probably too apathetic to write to us. There are a postcard intimating their desire to receive the weekly *Record* with its doubled subscription. These readers are waiting probably for the printed form which will officially bind them to the terms of the change. Will every reader of the *Record* have the goodness to send us a spontaneous expression of his or her wish in this matter.

SHORT ITEMS AND PERSONALITIES

The Secretary of State has sanctioned the proposal for improving the pay of Military Assistant Surgeons of the Indian Subordinate Medical Department. The service will be divided into four classes, on Rs. 85, Rs. 110, Rs. 150, and Rs. 200 respectively, the existing class on Rs. 60 being abolished. Promotion will be after certain fixed periods of service, the highest class being attained after nineteen years' service, instead of the present average of twenty-four.

Surgeon-Major-General Bathbridge has submitted a vigorous protest to Government against the abolition of the post of Secretary to the Surgeon-General from the 1st instant. Meanwhile Surgeon-Captain Burnet continues in the appointment, the Surgeon-General having proposed to the Government to allow the Secretary to continue *pro tem* pending a decision, after the consideration of the points set forth in the protest.

The nursing work at the General Hospital, Rangoon, is being carried on by two English nurses recently imported by the Municipality for three years' plague duty, and others employed locally. Apparently Doctor Thomas, in charge of the hospital, who is also Port Health Officer, Rangoon, has construed the general strike as meaning resignation, and has employed new hands accordingly.

The Calcutta Medical School contemplates relinquishing its teaching in the vernacular. It will it is hoped limit, not only on teaching its classes in English but formulate a new curriculum, embracing the matriculation of the Calcutta University as its educational standard of admission, and a complete course of lectures and classes equal to the requirements of the General Medical Council of Great Britain.

The Calcutta Health Officer has submitted the following important Bye-law for sanction by the Municipality:—“No person who is afflicted with leprosy or who has large open sores shall engage in the sale, or preparation for sale, of any article of food intended for human consumption, or enter the places where such article of food is prepared, stored or exposed for sale.”

The Edson Hospital does not at present enjoy a popular reputation for good management. It is said among other things that the work of administration is not carefully supervised as it should be. The success of this movement in the Native Women's Society, and the great lack of the work that should be done by the hospital management in the native social structure.

Medical Practitioners throughout the Indian Empire, and members of the Indian Medical Services are kindly requested to send Original Articles and Clinical Reports of cases for publication in the Indian Medical Record. This must be done if the local medical profession is to remove the reproach being cast upon it of apathy and neglect of its duty in literary matters.

Members of the Indian Medical Association who have not yet received their membership certificates are requested to apply for them at once to the Secretary.

Members of the Indian Medical Association who have not received a copy of the Third Annual Report of the Association, or previous Reports, are requested to apply for them at once to the Secretary.

Members of the Indian Medical Association whose subscriptions are in arrears are requested to forward their dues to the Treasurer without delay.

On and after the 1st October all communications for the Indian Medical Record whether for the Editor, Proprietor or Manager, should be addressed to 80, Park Street, Calcutta.

Do you wish the "Record" to become a "cheap" paper? Kindly send your reply on a post card.

THE WOUNDS OF THE ABDOMEN, CALLED BY STONES

PARTICULARLY rich as our stores usually in abdominal wounds, the interest has of late been especially directed to non-penetrating wounds caused by blunt force, for within a few years an unusual number of such cases has come under our observation, all of which were unusually interesting and instructive from the diagnostic and therapeutic difficulties which they presented.

Concerning the principles to be observed in the treatment of penetrating wounds of the abdomen, surgeons have of late been completely unanimous, and it is probably universally accepted that when a stab, shot wound, or similar injury penetrates the abdomen immediate laparotomy is indicated. In the treatment of non-penetrating wounds, however, which present greater diagnostic difficulties than the others, there is as yet no settled rule, and it is only in the last few years that such have been raised in favor of earlier surgical treatment in these cases also, in opposition to the former expectant treatment, according to which operative measures were delayed until there was undoubted evidence of wound of the internal organs.

I will for the present confine my attention to our experience in abdominal contusions complicated with wounds of the intestines. It is no intention of mine to follow the general custom of exhibiting startling recoveries, our experiences have been very trying and sad, but on that account they have been doubly instructive. We do not hesitate to publish our unfortunate results, hoping that they will lead to greater success both in our own hands and in those of others.

I will refer at another time to the wounds of other abdominal organs, as for instance the stomach, liver, kidneys and spleen, merely remarking *en passant*, that the spleen appears to be peculiarly susceptible to injury, in accordance with what is generally believed.

In an investigation made into this subject at my instance, by MURKIN, he found that in 52.2 per cent of all deaths, caused by wounds of the abdomen due to blunt force, the spleen was more or less injured.

In the last year we have observed seven cases of abdominal contusions produced by blunt force in which the intestines were wounded. Five of these in the short period from December 1895 to the middle of March 1896.

I. B. L., 35 years old, was on the evening of the 7th April 1896, struck so severely in the neighbourhood of the navel by the pole of a wagon that he fell to the ground, and had to be carried home.

On account of the increasing pain he was brought to the clinic 15 hours after the injury, he complained of severe pain in the lower portion of the abdomen on the left side. He appeared happy. Pulse 96, temperature 101.1°F, no tympanites, percussion note normal over the abdomen, the urine was drawn off with a catheter and was normal. No other injury could be discovered, 30 hours after the injury he vomited bile colored and blood-stained matter, during the night he vomited several times.

Thirty six hours after the injury, temperature 99.6°F, pulse very small, hardly perceptible, collapse. Left lower half of the abdomen very painful on pressure, slight tympanites no vomiting, no motion passed, but only flatus, 48 hours after the injury tympanites more marked, no vomiting, feels well.

10th April.—Morning temperature 99.7°F, on the other hand pulse 120, very small, tympanites and tenderness have

• By Dr. Adolf Schmidt, from the *Minchster Surgical School*. (Specially translated from the *Minchster Medizinische Wochenschrift* for the *Medical Record*.)

spread all over the abdomen, after the evening of the 11th, when the injury, he vomited greenish, acrid matter, no sign of blood, tympanites very marked, pulse very small, diminished, severe collapse which lasted to the evening of the 15th, and in which he died 70 hours after the injury.

The treatment consisted of opium, stimulants, and supported by subcutaneous injection.

Post-mortem.—Perforation perforated, the abdomen which was much swollen contained foetid fluid, the loops of the intestines were stuck together and to the omentum by a thick purulent material, and were much distended with gas; this gas escaped from a perforation in the upper part of the small intestine of the size of a lentil. In addition there was hypostatic pneumonia of both lower lobes and oedema of the lungs.

As vomiting only appeared 30 hours after the injury and soon stopped, and as the patient felt well, it was concluded, that there was no rupture of the intestine and that the admixture of blood came from a tear in the mucous membrane, probably of the stomach.

At first the tympanites was very slight and only what could have been accounted for by paralysis of the intestines from the injury, or by infection by micro-organisms, which might have passed through the injured intestinal wall. It was only 60 hours after the injury that vomiting again appeared, the tympanites then developed rapidly and the distension diminished and severe collapse set in.

The diagnosis of intestinal perforation was now easily made, it had previously been masked probably on account of adhesions which subsequently broke down, but on account of the severe collapse it was too late for an operation.

II. H. JOSEF, 27 years old, was on the 29th September 1896, bruised in the region of the navel between an iron beam and a furniture wagon. Shock was present on admission, pulse 80, very small, severe pain in the abdomen, no tympanites, liver dulness normal; no effusion into the peritoneum.

Twelve hours after the injury tympanites more marked, vomited twice, soon afterwards considerable effusion into the peritoneal cavity was made out. The whole of the abdomen was tender, pulse 112, severe collapse.

A wound of the intestines being diagnosed, 16 hours after the injury, laparotomy was performed, there was a large amount of coagulated blood about the transverse colon and lesser omentum which was separated from the stomach for about 4 inches. The abdomen was full of fluid, the small intestine was distended, the whole of the serous covering reddened and coated with purulent matter.

Close to the vertebral column, in a collection of effusion which was stained with blood and bile and mixed with air bubbles, an open end of intestine was found, the edges were bruised and the mucous membrane protruded, it corresponded to the horizontal part of the duodenum. To the left of this there was a second end, it appeared that the freely movable jejunum had been transversely torn away from the duodenum, the second end was also bruised and the mucous membrane protruded. In order to unite the ends as quickly as possible Murphy's button was used, one end was easily introduced into the jejunum, but there was considerable difficulty in introducing the other into the duodenum, on account of its being less movable; the serous coat was attached around, it was soft and easily torn.

The next morning the patient died collapsed.

Autopsy.—There was a quantity of bloody fluid in the abdomen. The stomach and intestines were tightly distended and covered with thin purulent exudate. When the stomach

the patient was in a state of collapse, the pulse was barely detectable.

At 10 A. M. the patient was in a state of collapse, the pulse was barely detectable.

The clinical course of the case had indicated the gut involvement, due to the abdominal contents, the rapid onset of collapse led to the suspicion of a severe intestinal injury; the character of the wound explains the comparatively late occurrence of tympanites and vomiting of bilious matter. Diffuse peritonitis was found at the operation and this combined with the collapse rapidly caused death. A serious complication was present in the wound of the omentum and contusion of the colon, which would probably have led to gangrene.

III. K. FARRIS, 45 years old, at about 6 P. M. on the 4th December 1897, was struck on the lower part of the abdomen by the corner of a heavy oaken plank which fell from a wagon. On admission late the same evening, he felt well, there was scarcely any sign of collapse and he only complained of severe pain to the right of the umbilicus. The abdominal muscles were tense, but there was no apparent dullness, no tympanites, he vomited mucus once while being examined, he passed a restless night and vomited bile stained fluid once.

At 8 A. M. on the 5th, he became collapsed, pulse scarcely perceptible, severe pain just below the umbilicus, slight dullness on the right side below and behind, the diaphragm was pushed up, liver dullness normal. No motion, no flatus.

At 11 A. M. 17 hours after the injury, a wound of the intestine being suspected, laparotomy was performed.

The incision was made over the seat of the greatest pain, along the outer edge of the right rectus muscle; there was a large effusion of blood in the connective tissue. On opening the peritoneum a quantity of muddy brown odourless fluid rushed out, in this the remains of food was detected. The parietal and visceral peritoneum was much reddened and coated with fibrino-purulent exudation.

In a loop of the small intestines there was a hole $1\frac{1}{2}$ cm in diameter, with bruised edges; the edges were excised and the hole closed with a double row of stitches. About 10 cm. lower down there was a second wound which cut the gut more than half through and the same distance further on there was a third perforation of the size of a pea, the intestine between these presented several bruises varying in size from a pea to a fig; ana place, they were brown in colour, and dry in appearance.

To stitch up the largest opening would have much reduced the size of the lumen of the gut.

Excision of the whole of the injured part about 40 cm in length seemed indicated, but it was considered inadvisable on account of the low condition of the patient, therefore the loop of intestine was covered with stiff protective and warm compresses, and drawn out of the peritoneum; the wound was closed with plugs of sterile gauze and 1000 cc. of hot salt solution injected subcutaneously.

In the afternoon he felt comfortable, vomited once, pulse quite small. The next day the patient felt well, the pulse was intermittent, but not altogether bad.

On the 7th, relatively good night, the abdomen was not distended, when the warm dressings were changed, to be going on well and there was no rupture at the bruised places.

On the 8th, December, six days after the injury, the patient was feeling well, there was no tympanites, and no tenderness in the abdomen; but the tongue was dry and the pulse small and frequent. In the night he suddenly collapsed and died.

At 10 A. M. the patient was in a state of collapse, the pulse was barely detectable.

The following notes subsequent to the operation and to the abdominal wall, under the great incision there were two places with deep punctate oradation, the former the opening of the former was the additional between the loops of intestine.

There was found in addition extensive degeneration of the heart, multiple infarcts in the spleen, fatty liver, chronic granular gastritis and a tubercular lesion in the right lung. In spite of the severe nature of the intestinal injuries (three large perforations and much bruising besides) we at first had hopes of saving the patient's life. There was no general septic peritonitis, but only a circumscribed fibrino-purulent peritonitis,—probably due to the not very infective character of the intestinal contents, the relative earliness of the operation by which much of the fluid was evacuated, as well as the escape of the rest of the abdominal cavity by gauze plugs, and the rapid adhesions that formed. The patient felt comparatively well, the temperature rose for the first time slightly before death to 100.4° F, otherwise it was normal. Death however resulted from final exhaustion brought on by the escape of the contents of the intestines from the paper opening (particles of food were found in the abdomen) as well as by the other changes which were noticed and especially by the degeneration of the muscles of the heart.

IV. D. JOHANN, 29 years old, was on the 9th December, 1897 at 4 p.m. kicked by a horse several times in the lower part of the abdomen and on the shoulder he could not escape and vomited immediately after the first kick.

Several hours after the injury the patient was brought to our clinic in a severe state of shock. On the right side of the abdomen above the symphysis there was an indurated swelling, the abdomen was very tender, there was dullness to the breadth of 8 or 4 fingers over the dependent parts on both sides. Pulse small, 72, intermittent every 3 or 4 beats, severe singultus; he twice vomited a quantity of bile stained mucus—12 hours after the injury he felt fairly well, Pulse 100 regular, temperature 101.4° F; slight tympanites; no more vomiting, urine drawn off contained no blood.—24 hours after the injury the tympanites was worse, the pulse was good and he felt well, no localised pain, no fever.—48 hours after the injury severe vomiting occurred, tympanites quickly increased. Pulse very small, 108, temperature 101.4° F. Laparotomy. The incision was made in the middle line; the abdominal cavity and especially the pelvis contained a large quantity of foul smelling fluid mixed with pus, all the intestinal loops were covered with purulent matter; diffuse septic peritonitis.

As even before the operation the patient was in an extremely weak and collapsed condition, and as the state of things found in the abdomen held out no prospect of recovery, I did not seek further for the perforation that was certainly present, but plugged the abdominal cavity and especially the pelvis with large gauze compresses and partly closed the abdominal wound. The patient stood it well (1000 cc. salt solution was injected), but died 18 hours afterwards (48 hours after the injury) was delirious, his pulse very frequent with high fever.

Autopsy.—Diffuse septic peritonitis, Clotted in the spinal column and lying over it there was a perforation of the size of a plum stone in the small intestine with bruised edges; there was a foul smelling exudation of pus mixed with fecal matter throughout the whole of the abdomen. In addition there was hypostatic congestion of both lungs and a tumor in the spleen.

the patient was found in a state of unconsciousness, and it was not until he had been found by the nurse that the patient was brought into the hospital. The patient was found in the street, lying on the ground, and was brought into the hospital by the nurse. The patient was found in the street, lying on the ground, and was brought into the hospital by the nurse. The patient was found in the street, lying on the ground, and was brought into the hospital by the nurse.

At 10 P.M. on the 28th January the patient was found in the back with such severe pain that he became unconscious. He was found by the nurse, and was brought into the hospital. The patient was found in the back with such severe pain that he became unconscious. He was found by the nurse, and was brought into the hospital. The patient was found in the back with such severe pain that he became unconscious. He was found by the nurse, and was brought into the hospital.

A large incision was made in the middle line, at once exposing the abdominal cavity a quantity of gas and bloody fluid rushed out. On the left side of the abdomen the intestines were much inflamed, but shining, on the right side they were stonic and covered all over with granulation tissue a portion of one of the folds which was tightly bound with adhesions, there existed a mixture of feces and pus, a small portion of the adhesions was carefully removed and disclosed in the small intestine, above the ileum, two perforating tears close to one another, these extended for some distance into the mesentery, in which there were two other rents. The perforations and the holes in the mesentery were stitched up, and the wound closed.

The patient collapsed 12 hours after the operation.

Autopsy.—Diffuse facultative perforation, peritonitis; intestines inflamed, tightly adherent to one another; in the abdomen a quantity of stinking fluid mixed with feces; there was no other perforation. There was in addition pneumocystic degeneration of the cortex of the kidney, and edema of the lung.

The clinical indications pointed to secondary perforation of a bruised and necrotic intestine, due to the two large tears in the ileum were caused directly by the injury, but they were for the most part closed by rapidly developed adhesions, the adhesions were probably formed during the movement of the patient and then followed rapid perforation as the result of the escape of the intestinal contents into the peritoneal cavity.

In spite of the previous operations, it was not until the patient was in a threatening condition, that the operation was performed.

The patient was found in a state of unconsciousness, and it was not until he had been found by the nurse that the patient was brought into the hospital. The patient was found in the street, lying on the ground, and was brought into the hospital by the nurse.

The patient was found in the street, lying on the ground, and was brought into the hospital by the nurse. The patient was found in the street, lying on the ground, and was brought into the hospital by the nurse. The patient was found in the street, lying on the ground, and was brought into the hospital by the nurse.

There was moderate shock; pulse good, 78. The patient was found in the street, lying on the ground, and was brought into the hospital by the nurse. The patient was found in the street, lying on the ground, and was brought into the hospital by the nurse.

An hour and a half later (4 hours after the injury) the patient complained of increasing pain and tenderness.

Laparotomy.—The incision was made in the middle line, a quantity of muddy fluid, without focal matter, and containing mixed with pus was evacuated. The perforation opening was only found after looking through a great part of the intestines, it was situated about 30 cm from the cecum, which had an unusually long mesentery and was lying in the middle of the abdomen.

The perforation was about 1 cm in length and the mesentery membrane was torn most extensively.

The intestinal wound which was opposite the attachment of the mesentery was stitched in two stages, the serous membrane was also stitched. Toliotta of the abdominal cavity (careful swabbing with saline compresses). The cavity was stitched and 1000 c.c.m. salt solution injected. 17-1-98, he passed a good night, no vomiting, passed flatus. Abdomen not tender. 18-3 Had pretty severe pain in the night, bled. Vomited several times. Transverse colon (?) appeared much distended Patient somewhat haggard; pulse strong, 100. Temperature normal. 19-3 Patient still more haggard, epigastrium distended, blood-stained vomiting, right side of the abdomen somewhat tender. Pulse weak, 120, temperature once rose to 100.4°F. Abdomen still normal, 1000 c.c.m salt solution injected subcutaneously. 20-3-98, vomiting continues, liver dulness imperceptible to the left, normal on the right. The stomach was washed out and about 2 litres of gastric juice and altered blood evacuated, after that he died.

Abdomen no longer so distended. Some vomiting, no more blood. Temperature normal, pulse 120, tongue moist, during the night there was severe pain in the abdomen, which became more distended; the breathing was affected; about midnight collapse set in, with rapid breathing and at 5 A.M. he died (8 days after the injury).

Autopsy.—No peritoneal perforation, but the position of the intestine had been such that the finger could be passed through it. The intestine was found in the middle of the abdomen, it was situated about 30 cm from the cecum, which had an unusually long mesentery and was lying in the middle of the abdomen.

The liver dulness began three fingers' breadth above the margin of the ribs and reached to the fifth rib, pulse 110, temperature normal; some eructation, but no vomiting, no flatus passed since admission, general condition good, nine days after the injury condition unchanged, but the pulse was weaker, temperature 101.2 F. Laparotomy. Incision in the middle line, from the opening was evacuated a quantity of yellow matter, mixed with pus and without a feculent smell.

The perforation lay concealed in the posterior wall of the stomach, probably sunk during the prostration of the patient. The patient had the injured loop been in this position, it would have been wounded, there were no signs of shock. The third day after the injury jaundice appeared. If it had been due to a lesion of the liver, there was, however, no fever, and no other bad consequences. Had this perforation been discovered and operated on, and the perforation closed, he would probably have died.

Statement of Deaths from Principal Diseases in Calcutta during the week ending 17th September to the 23rd October 1890.

Current Medical Literature

EXOPHTHALMOS

Exophthalmos Treatment of Exophthalmos and Exophthalmos

It is very strongly recommended by Dr. JOHN F. WHEELER, when associated with hemorrhage from the bowels, pneumonia, or pleuritis. Arguing all the whilst-player's marks that though it is the last War Wicks, that win the hand, it is rather the opening lead that determines the final issue, he notes that the daily damage from the typhoid toxin is no greater in any one of the 20 days the fever lasts, and the compensation at the close is only the resultant of forces put in operation at the beginning and whose accumulated effect is more devices towards the end. Wherefore he thinks the stimulation of the nervous system is the main thing to be accomplished and the colder the cold water bathing (baths repeated every 3 hours and each lasting from 15 to 45 minutes according to the severity of the case) is begun, the better, for though it does not itself destroy the toxins it combats their ill effects through (1) the abstraction of heat and by (2) stimulating the nerve centres to maintain functional activity and nutritive integrity by thermic and mechanical shock, which latter operates by (1) exciting the vasodilator nerves to remove internal congestion by bringing more heated blood to the surface to be cooled by the water and (2) by stimulating the autonomic nerves over a wide area to thereby reflexly stimulate the entire nervous system.—*Mod. & News.*

Statistics of Exophthalmic Goitre.

In the *International Medical Magazine* for April, 1898, HARRIS, of Philadelphia, publishes a short contribution to the statistics of exophthalmic goitre, based upon the analysis of 227 cases. 165 were females, 43 were males (44 to 1). The oldest female case was 68, the youngest 9. The oldest male case was 66, the youngest 16. The average age of all was between 30 and 31 (in 212 cases 30.33 years). The conclusions formulated by the writer are as follows:

1. That exophthalmic goitre occurs approximately 4.5 times as often in females as in males among all people.
2. That the disease is most common during the period of active adult life, occurring earlier in females than in males.
3. That the disease is uncommon, if not rare, in the black race.

Referring to the surgical treatment of exophthalmic goitre, JENNINGS critically reviews the various surgical methods employed, and gives a detailed description of an operation for relieving the entire cervical sympathetic. He states:

1. That in true exophthalmic goitre surgical interference is both dangerous and ineffectual.
2. Simple section of the cervical sympathetic is useless, though partial resection, including the first two ganglia, may give lasting results.
3. The operation of section in total and bilateral resection of cervical sympathetic.—*Treatment.*

Nerve Disorders in Symptomatic Diseases.

Two cases illustrative of the nerve disorders which attend upon symptomatic diseases are described in the *Annales de Médecine et Chirurgie Infantiles*. The underlying fever in each case was measles. In both a mania, delirium was the most marked symptom. This condition appeared in one case as a sequel on the twenty-first day of illness and was ushered in by mental depression and attended by hallucinations. This patient gradually recovered. In the other infantile measles

appeared with the invasion of measles and was characterized by the same mania. The onset of the mania was delayed till the eighth day of the disease. The symptoms began to abate, but the mania was not cured. The age was 10 years and 12 years respectively. It these data are taken into account they are supported by the experience of other observers. They teach the importance of the nervous element as a factor in the pathology and treatment of children's diseases. This is probably of more consequence at or about the period of puberty, though it can at so age be overlooked. It is therefore the more to be considered in connection with cases of "suppressed" eruption. In its therapeutic aspect it may necessarily remind us of the paramount value of measures to hasten the appearance of the rash and frequently also of judiciously sedative treatment.—*Lancet.*

Carnogen or Red Bone-Marrow in the Treatment of Anemia.

AFTER two years consumption of BLAND'S pills, anemia, large doses of iron and tonics of all kinds in the vain hope of curing her chlorosis, which got worse instead of better, ETHEL C., aged 16 years, attended DANA'S clinic for nervous diseases, where Dr. ROBERT L. WATKINS placed her on Carnogen 3 1/2 t. and no other medicine; because while she had severe headaches in the brow running to the vertex, pains in the back—she had never menstruated—faintings, apoplexy, digestive disturbances, constipation furnished ample evidences of weak circulation, examination showed no objective signs of disease except a most pronounced and striking, anemia. She improved so rapidly that in a month after treatment her pallor decreased, there was very little headache and no more fainting fits while there was a large increase in the red corpuscles, which had also improved considerably in appearance, number, tone and form.—*Amer. Med. Surg. Bul.*

Scarlet Rash after Enemata.

EIGHT cases are reported by Dr. G. H. BURFORD, of an ordinary soap water enema being followed, within a few hours, by an excessively irritable, rapidly developed and widely diffused rash chiefly involving the extremities and trunk, and lasting from 36 to 48 hours when it disappeared as mysteriously and as quickly as it arose. It was sometimes accompanied by pyrexia and malaise. Two similar cases are also mentioned by Dr. C. W. SUCKLING, who cautions against the too frequent and sometimes unnecessary employment of clysters as he has occasionally noticed mild symptoms of scarlet fever arise after the use of enemata, and he thinks that the rash is due to toxins caused by the absorption of fecal matter liquefied by the absorption of a large quantity of warm water.—*Brit. Med. Jour.*

Epilepsy from Lead Poisoning.

A DAVIDSON reports a case where a man working in very confined places while painting the lead at a ship, was admitted to hospital complaining of headache and vomiting in an insidious manner. He soon had delirium followed by epileptic fits and unconsciousness and died on the fourth day after admission. Chemical analysis of the blood showed presence of 0.6 grains of lead which was the largest safely large amount in the blood that has been found. There was no kidney disease. Experiment showed that the lead was to lead poisoning.—*Lancet.*

the operation had been done, the conditions for the last operation were as follows:

The advantages of vaginal operations were (1) that the incision was not deep and (2) that the incision was not of sight. The disadvantages were that it was impossible to introduce the hand, only two fingers could be introduced and only the organs within reach of the finger could be removed. The conditions for which he would perform these (1) for plastic operations on normal sized uterus and ovaries, (2) for the removal of myomata up to the size of a child's head, (3) for the removal of ovarian tumours.

Dr. SARGENT of St. Louis said that when it was possible to get one ovary at tube he would do so. He strongly advocated the MCKENZIE method of drainage. Dr. FELLING of Halle, said that in doubtful cases he makes a puncture with the DISSELY aspirator. He protested against the practice of removing the uterus and leaving one ovary.

Dr. MARTIN said that he made a point of inquiring into the history, for if due to gonorrhoea, expectant treatment was adopted, when due to sepsis it was less liable to be benefited by medical treatment. He did not use drainage.

Dr. McCANN delayed operation until absolutely necessary. Dr. BYRNE said there were many cases in which the question of pus could not be settled until the abdomen was opened.

Surgical Treatment of Pelvic Inflammation.

In a discussion on this subject, Dr. CULLINGWORTH drew attention to the backwardness of this country in the treatment of these diseases. He put forward the following as points open to discussion.—(1) indications for operation in pelvic inflammation; (2) time to be chosen for operation; (3) methods of operation; (4) the extent of the principles of conservatism. In this paper he would deal with the first two only. The indications for operation were usually started as (1) inflammation of the connective tissue, and (2) inflammation of the peritoneum. As to pelvic cellulitis there was a general agreement that when there was no suppuration, no surgical treatment was needed, when there was the pus should be let out. In pelvic peritonitis operative treatment was not called for when due to simple catarrhal salpingitis, but only when pus was diagnosed; when operation was indicated after subsidence of acute symptoms and when bimanual examination showed a mass in DOUGLAS' pouch.—*Brit. Med. Jour.*

Verminous Tumors in Children.

FRANKLIN, of Nancy, writing on this subject, says that generally speaking intestinal worms are not considered likely to produce suppurative or perforative lesions. However, in the case of lumbricoid worms, this parasite has been so often encountered in different lesions that it has been agreed to designate these as verminous abscesses or tumors. These abscesses are generally in the abdominal parietes. They may cause an encysted peritonitis.

By what mechanism do these lumbricoids leave the intestine? FRANKLIN attributes their migration to an old perforation and a change to the skin. When the abscess is opened the passage has disappeared. LEONHART believed that these worms could, by continued pressure, perforate the intestine and then escape through. Others admit that perforation can only come by pressure after a modification has occurred in the intestinal lining through an enterocolitis. FRANKLIN believes that the parasite pierces a capsule and then enters the cavity of the abscess. FRANKLIN also

believes that in these patients there is not a continued escape of worms, but that the worms are retained in the abscess, and that the abscess is caused by the worms. He believes that the worms are retained in the abscess, and that the abscess is caused by the worms. He believes that the worms are retained in the abscess, and that the abscess is caused by the worms.

The abscesses due to threadworms are not of great importance for discussion, the author having a more convincing, from which he draws the following conclusions. Threadworms can produce an abscess in the rectum, and at a distance from it, abscesses in which they multiply in great numbers. These abscesses have been produced by penetration of the threadworms into the female laden with eggs into the rectal cavity. These deposits in the cellular tissue. These eggs may also be conveyed by the lymphatics.

An uncleanly individual may contract the eggs of the parasite by transporting the eggs of the parasite from the rectum.—*Med. Age.*

Differentiation of Brain Tumors.

L. BRUN in an address delivered at the Congress of Medicine said that although many of the symptoms of frontal and cerebellar stasis are identical, he considers that monoplegia, Jacksonian convulsions, tonic deviation of the head and eyes to one side, and especially motor stasis, denote frontal stasis. On the other hand, paraplegia and alternating hemiplegias, visual paralysis on the side toward the tumor with crossed hemiplegia, double paralysis of the optic muscles and paralysis of the facialis and abducens, distinguish cerebellar stasis. He does not lay much stress on homonymous hemianopia unless it exists on the right side from the first, combined with stasis and optic atrophy, when it indicates a tumor in the medulla of the left occipital lobe. He concludes by recommending paracentesis as extremely valuable. When the sensitiveness, tympanism and cracked pot noise are pronounced and extensive, they indicate plainly the general diagnosis of tumor, and when distinctly localized they point to its seat with precision, especially when the indications of the paracentesis coincide with the symptoms observed. In the difficult differentiation of tumors in the central convolutions and neighborhood, distinctly circumscribed paracentesis sounds will often help more than even the cerebral symptoms, as they are scarcely possible unless the tumor is located at least near the cortex.

Suture of the Bile-Duct.

In the *Bulletin of Johns Hopkins Hospital*, April, 1906, Professor W. S. HALESTED describes an ingenious device to facilitate suture of the bile-duct. He states that to make an incision in the normal ductus communis choledochus has been considered so impracticable, not to say impossible, and the result of suture even of the abnormally thickened duct so uncertain, that it is the practice of all surgeons to wait weeks, months, or even years for the duct to dilate and thicken rather than interfere promptly in cases of obstruction of the common bile-duct by calculi. The operation may be postponed to "give nature a chance" to expel the stone, but never for the sake of giving the duct time to thicken. The dangers of this practice are many, and when at last the surgeon interferes the patient is very weak. By using HALESTED'S hammers which he has devised Professor HALESTED has sutured the common duct in dogs five times, and the common duct twice and the cystic duct once in man. The wall of the duct is clearly exposed and two protection sutures are inserted to act as retractors. The incision is made between them. The stone having been removed the threads are drawn apart and a hammer of the proper size is introduced. The duct is gently raised from its bed and drawn by the hammer towards the operator. Making stitches of silk are then applied, one over the heel and the others in front of the handle. Although the same stitches are used they necessarily perforate the wall of the duct, but no harm results as the duct is usually healthy.—*Lancet.*

Obstetric Surgery.—The following cases are reported from the University of Edinburgh. In the first case, a woman, aged 35, had been married for 15 years, and had borne 10 children. She had been suffering for some years with a tumor in the lower part of the abdomen, which was found to be a large fibroid tumor. The tumor was removed by the abdominal method, and the patient recovered well. In the second case, a woman, aged 30, had been married for 10 years, and had borne 5 children. She had been suffering for some years with a tumor in the lower part of the abdomen, which was found to be a large fibroid tumor. The tumor was removed by the abdominal method, and the patient recovered well. In the third case, a woman, aged 35, had been married for 15 years, and had borne 10 children. She had been suffering for some years with a tumor in the lower part of the abdomen, which was found to be a large fibroid tumor. The tumor was removed by the abdominal method, and the patient recovered well.

The tendency to large fibroids is not due to any special cause, but to the fact that a pregnant woman is the last time and most anxious thought of the physician is taken up with the obstetric cases.

Unaided Labour.

Dr. James Watson of London reported a case of a woman who was delivered by operation and post-mortem. The woman was delivered in July 1895, but no labour pains were felt. There were pains and hemorrhage. At the time of delivery she was very ill, abdomen enlarged, and no fetal sounds or movements were perceptible. After several days, operation was undertaken. When the placenta was removed, the fetal parts could be felt, and the middle line and fetal fluid escaped. A placenta weighing 12 pounds removed. Uterus contracted. The patient died 28 days after operation. Examination proved conclusively that gestation was normal.

Benign Uterine Catarrh.

The symptoms of this disease: (1) Those associated with catarrh and no hemorrhage. (2) Those associated with catarrh and slight hemorrhage, and (3) Those associated with catarrh and hemorrhage. In the first case, hemorrhage is the main, if not the only, symptom. In the second case, hemorrhages are in the main due to (1) beginning cancer, or (2) the recrudescence of a chronic catarrh from a form of uterine catarrh which is not malignant as its cause. There symptoms are usually those of malignant disease. There are present emaciation, general cachexia and emaciation, occasional night sweats, frequently pain in abdomen and back, and the discharge, which is watery and semipurulent, and frequently contains a considerable amount of blood. "Thin" discharge is much rarer than in cancer. The odor of the discharge is usually offensive but not necessarily so. Examination shows the uterus slightly enlarged, or at least not normally shrunken, but not so large or fixed as in malignant disease. The introduction of the sound is very painful. The uterine mucous membrane is hypertrophied, swollen and easily detached. Microscopic examination of a scraping shows inflammatory changes, infiltration of leucocytes, and degeneration of cells, and granular degeneration. Under appropriate remedies, benign uterine catarrh will usually improve in a week or two, but this is of no avail in malignant disease. The difference between this disease and ordinary uterine cancer is that in the night, irregular and bloody pain; the early appearance of fetid discharge; the slight enlargement and mobility of the uterus.

As to the almost universal custom of applying a bandage to the lower part of the abdomen, it is not recommended. The only difficulty in the management of cancer is the diagnosis from malignant disease. This should be made. The treatment of cancer is not recommended; but hot fomentations, hot baths, and other treatments are recommended. The treatment of cancer is not recommended; but hot fomentations, hot baths, and other treatments are recommended. The treatment of cancer is not recommended; but hot fomentations, hot baths, and other treatments are recommended.

The Belly Band.

As to the almost universal custom of applying a bandage to the lower part of the abdomen, it is not recommended. The only difficulty in the management of cancer is the diagnosis from malignant disease. This should be made. The treatment of cancer is not recommended; but hot fomentations, hot baths, and other treatments are recommended. The treatment of cancer is not recommended; but hot fomentations, hot baths, and other treatments are recommended.

Periodic Menstrual Psychoses.

TRENKLE relates a case of delirium with hallucinations occurring at the menstrual periods in a woman 35 years of age who had given birth to a child some years previously. The attacks took place in January, March, April, and May of 1896, and on the two last occasions were followed by hysterical depression lasting for a few days. Such cases are rare, but may be met with either in early, late, or middle menstrual life, and may be acute, subacute, or chronic. The intervals between the menstrual periods are generally free from mental symptoms. The prognosis is relatively favorable, 68 per cent. ending in cure, but the condition may become chronic, or may be followed by dementia, or may be transformed into ordinary insanity or perhaps into acute periodic insanity. When there are coexistent lesions of the genital organs, removal of the ovaries may be indicated, and may sometimes give good results, but removal of ovaries should be had only after a long period of observation. Treatment in the attacks should usually be carried out in a hospital, and not in an asylum.—Brit. Med. Jour.

Treatment of Vomiting of Pregnancy.

GEORGEY is convinced that the condition of nausea and vomiting of pregnant women is due to reflex irritation of the digestive tube; that such irritation is caused by the pylorus and the different portions of the stomach, and more particularly in the ilio-cecal angle of the colon, and this painful contraction at this angle is a pathological sign of reflex hyperesthesia of the intestinal canal. The morbid symptoms vary from slight pain and tenderness to simple nausea or to uncontrollable vomiting. In the slow, light, progressive movements of the bowels, the patient is able to eat and drink, and the vomiting is not so severe. In the more severe cases, the patient is unable to eat and drink, and the vomiting is so severe that it is necessary to resort to medical treatment. The treatment of vomiting of pregnancy is not recommended; but hot fomentations, hot baths, and other treatments are recommended.

THE PATHOGENIC PROPERTIES OF MILK

By Dr. OWEN COLEMAN, M.D., F.R.S., F.R.C.P.,
Fellow of the Royal Society, Lecturer in Pathology,
University College, London.

Pathogenic Diarrhoea.—It is well known that the author, following on the discovery of the bacillus of dysentery for the purpose of determining the importance of tuberculous infection, discovered a bacillus which subsequently produced considerable diarrhoea through changes which occur after it has left the tuberculous organism under certain conditions of culture.

Samples of tuberculous material were obtained from deceased cases, the bacilli were grown in sterilized vessels and taken directly to the laboratory. These samples he designates as tuberculous milk. The other samples were taken from the milk sold at the railway stations and placed in sterilized bottles. These he designates as the mixed milks. The specimens were collected in both the summer and winter months. Some were prepared longer than others, dependent upon the distance they came. He found that as a general rule the composition of the milk of markedly diseased cows was that of the ordinary mixed milk, that the bacillus which has often been capable of producing irritation does not destroy the ordinary mixed milk supplied for consumption. In order to obtain a correct idea of the relative noxiousness of the mixed and unskimmed milks, the tuberculous milks were excluded from 119 samples above referred to. This left 42 samples of non-tuberculous unskimmed milks. A comparison of their pathogenic properties showed that 40.8 per cent. of the mixed milks proved to be non-irritating, 40.8 were locally irritating, and 19.2 per cent. were highly virulent. Of the unskimmed milks 60.5 per cent. were irritating, 33.3 per cent. locally irritating, and none of them highly virulent. A study of these same samples in order to determine the influence of time and temperature showed that the longer the time and the higher the temperature at which the milk was kept greatly increased the pathogenic properties of the specimens. The author concludes that infection of the milk outside of the udder and the conditions under which it is kept are the most important factors causing it to have irritating properties. He has found a close resemblance between the infection induced in guinea pigs from inoculations of milk which had given rise to outbreaks of epidemic diarrhoea, and that produced in guinea pigs by the injection of some samples of milk obtained in the market. From this he infers that milk must be one of the most potent factors in the summer diarrhoea of children. This view is confirmed by the fact that he has been able to isolate a bacillus from all the cases of fatal septicæmia due to milk injections the same as that obtained twice from milk giving rise to intense diarrhoea in children and adults. This is the only microbe which he found constantly present, and it retains its virulent properties through several subcultures outside the body. It closely resembles the bacillus coli communis in its pathogenic action. Its differences are quite within the limits of the ordinary variations of the *b. coli*, so much so, that he has as yet, been unable to positively affirm that it is not this microbe.—*Lancet Med. Rep.*

Proximity of Trees to Dwelling-houses.

The proximity of trees and shrubs to dwelling-houses is not generally considered in the light of a health problem, but the fact that it is to be so considered is stated by Dr. OWEN COLEMAN, Medical Officer of Health, Ealing. It may be mentioned in a popular London suburb, where trees and

shrubs are planted in the front and back gardens of the houses, that the proximity of trees and shrubs to dwelling-houses is a health problem. The large trees in the front and back gardens of the houses are scattered about the houses, and the houses are scattered about the trees. The perfect jungle that so many suburban dwellers make of their front and back gardens, and the trees and shrubs that are so prejudicial. They prevent the sun from reaching the houses, keep the ground damp and cold, and prevent the proper access of fresh and wholesome air to the lower part of the houses. During the night, the air in the houses is contained air naturally rises, and to some extent passes out of the upper part of the house, its place is supplied by air coming in at the basement or ground floor, and this air will be filtered through bushes and undergrowth mixed with the exhalations from damp soil charged with decaying organic matter, it is small wonder that some households find themselves specially liable to some throat or lung disease. These not infrequently are never assigned as to the possible cause, but incontinently refer it to the neighbourhood as a whole, and either go on suffering or go up and leave the place. The big trees (due regard of course being had to their soundness) have an important part in keeping up the salubrity and equable climate that is peculiar to that part of the Thames Valley. They serve as wind screens, and act the same part as a breakwater does in subduing the violence of the waves. Remove them to any large extent, and undoubtedly, as a consequence of becoming more wind swept, the temperature will be sensibly lower in winter, and the character of the whole of the district altered.—*Treatment.*

Accountability of the Physician.

THE law does not require of a physician or surgeon absolute accuracy, either in his practice or his judgment. The law does not hold physicians and surgeons to the standard of infallibility, nor does it require of them the utmost degree of care or skill of which the human mind is capable, but that, while in the practice of their vocation, they shall exercise that degree of knowledge and skill ordinarily possessed by members of their profession. This is the declaration made by the supreme court of Nebraska, in the case of *VAN SICKLE vs. POTTER*, December, 1897, which was an action brought to recover damages from Dr. POTTER and REYNOLDS for alleged negligent treatment of a kneecap fracture. The trial resulted in a verdict and judgment in favor of the doctors, which the supreme court affirms. The evidence, the supreme court holds, sustained the finding of the jury that the plaintiff did not contract with the plaintiff to effect for him a permanent cure, and did not contract to visit and treat him until he was cured. As to whether they had pursued the proper method in setting his kneecap, by wiring the fractured portions together, the supreme court says: "As is usual, the experts for the plaintiff agreed with his contention, and the experts on behalf of the defendants agreed with their contention"; and it decides that they were not guilty of negligence in the treatment given the plaintiff, including the leaving the point of a drill in the bone, when broken off, and leaving a hole in one of the pieces of the kneecap, owing to a movement of the plaintiff's leg. Upon the basis of the finding of the jury, as to whether the defendants agreed to visit and treat the plaintiff until he was cured, the supreme court holds that they were properly permitted to testify that on the date of their visit to him they informed him that they thought he would unless they should be requested to do so. It was held that in such a case testimony of the plaintiff's medical authorities as to the proper method of treatment was not competent evidence in the case, and that the jury was not bound to accept of the testimony of the plaintiff's medical authorities as to the proper method of treatment.

... ..

10-10-68

I have followed him to the end of his
 instrumental journey and I have seen
 how after twenty years of service
 applied for urgent leave when he was
 met by the British Empire and the
 stance that prompted the decision
 during his absence from his home
 died leaving a household of children without a father.
 The exigencies of the service were the great cause of
 withstanding local arrangements were also made for him.
 In contrast to this a second could tell him that after twenty
 years service in Burma, he "enjoyed" his "leave" for three
 months' privilege leave, while a contemporary who had
 spent more than that time of incessant duty in the heat
 and plague camps found no fault with his leave.
 The third man has had the experience of his Hospital Service
 being systematically sent back for one trivial ailment
 or another bringing "dust on his head and dirt on his feet"
 from his superior, till a certain late hour at the Home
 Manager's domicile was followed by happy results. With
 what cool confidence I have witnessed a confidence in the
 teeth of glaring improbabilities calculate the time when
 a certain appointment would be his and it was so. The
 "job" executed by our friend Mr. Manager Rake
 presents so many curious aspects of boldness, ingenuity,
 cunning, diplomatic talent, sallow effronance and great
 circumspection and forethought, that I have been
 prompted to make a collection of the precious lot and
 work up a literary *chef d'œuvre* for the edification of the
 public at some future date.

You would like to have proofs Sir? Well, that is just what you cannot obtain, at least proofs of that nature that would secure a legal conviction. But if this filthy, stinky disgraceful business is an open secret and known to the officers of the Service, *Examiners and Administrators*. Call for confidential communications from Assistant Surgeons and Hospital Assistants and the "altered evidence" contained in them will carry conviction to the uneducated mind.

What is the outcome of this state of things, to which we are concerned? Simply this: that no "privileges" of military men and servants of the State are to be taken for granted, as sanctioned by existing laws, and that no man is to be obtained only by manipulating the people, and making our status insignificant as it is regarded by the people, and their Managers, and our "Rights" are to be based upon as so much dirt. "Money" is the only thing that the Gentile Apostle saith we "shall have" and that will obtain National Dependence, and that will make us sturdy work and money makers.

"MILITARY RINGING" TITLES FOR ASSISTANT SURGEONS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Perhaps enough has been already written protesting against the insane and ludicrous suggestion of your correspondent "P" as to the above, but as he returns to the charge with re-doubled vigour in the last *Record* to hand, with an extra embellishment of "smiles" and rotten argumentative powers, it is high time he was pulled up short. One would have thought that the very sensible and extremely moderate retort of "An Old Assistant Surgeon" was enough to subdue "P" into a more sensible way of thinking, but evidently not.

His statement that the suggestion he put forward "had the approval of several of his colleagues" must I am afraid be taken *cum grano salis*, while personally speaking from a knowledge of the members of the service generally, it is a statement that I emphatically refuse to believe, and I challenge your correspondent to produce three men from the sum total of all the Presidencies who will come forward in the *Record* agreeing with his "suggestion."

One can quite understand the long and severely fought battle of the Commissioned Officers of the Medical Service for purely military titles which they have at last won, but they placed their banner of offense more on grounds of gaining social equality with their brother combatants which they feared was wanting in a quasi title. "P" in his enthusiasm for military titles and military "ring" would have us mount a dung hill to be buried in it completely when we get to the top of it, while he actually fails to produce any advantage socially, morally or professionally (?) in support of his contention I mean "suggestion." On yes, the "military ring" forthwith.

It seems a great pity for "P" that he wasted his military opportunities in allying himself to any branch of the medical profession for the military ring that he finds desirable would have rung for him to his heart's content in the "ring" of the "just" "good" "room-deteriating" with nothing more satisfactory, *per se*, etc. etc. I have no doubt that some of our officers as "P" must be aware of it, and I am sure that as my friend "Garm" would have said, "it is a shame to allow such fantastic ideas to come into the mind of any one."

(We trust our correspondent knows that officers do not write on the principles of "solid human pectorum" — Ed. I.M.R.)

BUBONIC PLAGUE CASES AT ANAND DISTRICT HOSPITAL CAMP: SIX MONTHS' WORK.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Of 59004, or a daily average of 2874, persons who were detained for observation at this camp between 24th November 1897 and 17th May 1899, no fewer than 641 received medical aid while 60 Hindus and 30 Muslims (i.e. Adults—58 males and 18 females and 2 children) were sent to the Plague Hospital, and of these 51 had plague of the bubonic type, 14 pneumonic, 5 septicaemic, 1 septic and 4 of the bubonic and pneumonic variety combined, and 26 of these recovered while the remainder died.

4 of these patients were over 50, 5 between 41 and 50, 9 between 31 and 40, 27 between 21 and 30, 25 between 11 and 20, and 7 under 10 years of age.

Though 1 case went as far as the eleventh day, 3 to the eighth, 7 to the fifth and 17 to the third day before the early signs were seen, still in 33 cases the plague manifested itself within 24 hours after infection, and the most prominent symptoms were;—utter lassitude, anxious face, moist saliva, white tongue, suffused conjunctiva, feeble pulse, monosyllabic "drunkard's speech," and later a very tender and painful bubo accompanied by delirium in 50 per cent. of the cases.

In the pneumonic variety which was the most fatal (10 deaths in 14 cases) the sputum consisted of pale red blood and the cough which was of a hacking character, was frequently followed by dyspnoea rarely by orthopnoea, while the chest felt sore with lancinating pains.

The bubonic variety which was the most common and the least fatal accounted for 59 cases in whom the buboes appeared as under:—

REGION OF BUBO	B	P	L	S	T
Inguinal	15	12	1	29
Femoral	7	12	5	24
Both Combined	1	1
Axillary	3	3
Submaxillary	1	2	...	3
Parotid	1	1
Total	28	27	4	59

The treatment which gave most satisfactory results was the exhibition daily of Liq. Hydrag. Perchlor (corrosive sublimate solution) six drachms divided over 24 hours: Under this the temperature markedly remitted and the delirium lessened, while the tongue became clean, there was a decided general improvement. Remarkable though the results given by this drug, we could not claim a definitely specific action for it, since the perchloride was tried in only 70 cases of plague. The buboes did nicely under repeatedly applied caustics, and it is satisfactory to note that so far no cases of plague occurred in Anand itself, even though 78 cases were detained from through passengers.

Yours &c., MARSHALL PRASADA, M.B.

TO THE EDITOR, "INDIAN MEDICAL RECORD,"

Of course I must admit that you have been trying your utmost and that an appeal has already been made for improvement in the prospects of both the classes, though the result is that the upper class is favoured and the poor Hospital Assistants' class is altogether neglected. I would most respectfully request you to be so good as to send in a reminder to the Government of India, to get at least some redress for our grievances. Hoping to be excused for the trouble and thanking you for the sympathetic disposition you have always shown towards the miserable class of Hospital Assistants.

BELGAUM, 8th October, 1898.

-10-

TO THE EDITOR, "INDIAN MEDICAL RECORD."

1.—They do not know sufficient English to be able to carry a medicine indent or keep their registers properly in the same language—which are most essential duties in the new employ to which they principally flock to

31. -- In college experience, even on a respectable salary, a small loss of dignity.

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Rs. 1 for subscribers and Rs. 3 for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTH.

FINK.—On the 24th September, 1898, at the Dingle, Glendalough, the wife of Major G. E. Fink, I.M.S., of a daughter.

DEATH.

GILLESPIE.—Oct. 6th, at Bombay, Anne Cecilia, the beloved wife of 1st Class Assistant Surgeon T. D. W. Gillespie, Home Surgeon, J. J. Hospital, Bombay, aged 57 years, and 3 months.

NOTICES TO CORRESPONDENTS.

Assistant Surgeon.—Regarding your complaint about the P. M. O.'s Head Clerk which we noticed in our editorial comments in last issue and your present further contribution on this subject, we quite understand how dangerous it is for junior officers to publicly represent complaints against their superiors' clerks, but if you or any one else will forward us evidence of an authenticated and convincing character regarding the frauds and the taking of illegal gratifications by P. M. O.'s Head Clerks, we promise you an immunity from every shadow of unpleasantness, for we believe the P. M. O. Her Majesty's Forces and the Director-General of the Indian Medical Service will take action against these reptiles on such evidence and crush them to death. They certainly deserve condign punishment and we shall gladly do anything to see them get their just deserts.

Aspirant (Assam).—Kindly quote in words the paragraphs you refer to, and we shall be able to advise you.

Railway Medical Man.—Apologizes for his reticence to the qualified Railway Doctor whom he aspersed.

H. F. D.—Transfer from one Presidency list to another cannot possibly involve loss of service or pension.

Hospital Assistant.—It is very pleasing to find one of your class respond appreciatingly to the proposed change to make the Record a weekly paper. No less than 617 Hospital Assistants have already signed to the doubled subscription.

A. D. M. (Peroneper).—We much appreciate your enthusiasm in the cause of your service and in the cause of the local profession generally. It is particularly gratifying that a few have to work for the many in the cause of reform, but if gratitude and co-operation do not mean anything, must not lose heart. Right and wrong.

W. C. E. (Jank).—Make your mark in your own pointment.

G. E. (Gent Yank).—Thank you for all the trouble you require in last number of the Record.

ABDOMINAL AFFECTIONS

OF THE OVARIES AND UTERUS.

THE SECOND OPERATION—A
SECOND TIME.

WILLIAM H. WATSON, M.B., F.R.C.S. (Edin.),
Surgeon to the Samaritan Free Hospital,
London.

In this paper I include every case in my practice in which an abdominal section has been performed a second time, with the exception of six cases already recorded.* I have selected these cases for publication together because their histories illustrate a considerable number of complications, accidents and causes of death which may occur in abdominal surgery, and because very few of them are without special points of interest. The cases may be divided into three groups. In the first eight the second operation was performed on account of a return of disease after a period of good health. The second group consists of five cases in which the first operation was insufficient to effect a cure. In the remaining thirteen cases the second operation was required on account of some complication arising as an immediate or a remote consequence of the first.

GROUP I.

CASES 1, 2, and 3.—The first three cases were examples of the growth of an ovarian tumour in the second ovary after the removal of an ovarian tumour. In Case 1 the second ovary had completely separated from its normal connections, probably by twisting, and was nourished by adhesions in its abnormal position. The patient is alive and well. In Cases 2 and 3 the patients very nearly died from obstruction of the bowel during convalescence. The former is alive still; the latter died from pneumonia at the age of sixty-five years, nearly five years after the second operation.

CASE 4.—In this case an ovarian cystic tumour had been removed by another surgeon three and a half years before I saw the patient. I diagnosed a second cystoma, but on opening the abdomen I found a very large collection of ascitic fluid, encysted by peritoneal adhesions. The left ovary and tube were absent. The right appendages were dotted over with a granular growth which might have been either tuberculous disease or papilloma. I removed the ovary and tube and the patient made a good recovery.

CASES 5 and 6.—In these cases it was supposed that both ovaries had been completely removed for neoplasms before the patients came under my care. In each case I was informed of this by the gentleman who had operated. Nevertheless, I performed in each case an operation in no way differing from an ovariectomy with deep enucleation of the growth, except that the Fallopian tubes were absent. Both cases recovered. These two cases show a local recur-

rence of the disease. The condition is a singular one, and I am not aware of any other instance of such a local recurrence.

CASE 7.—This case was particularly interesting because of the long interval between the first and second operations. The patient was an unmarried woman who had been married in 1871 until October, 1882, when she began to suffer from abdominal difficulty in keeping the bowels open. I saw her on January 26th, 1894, and she then had an abdominal tumour, intestinal obstruction with abdominal distension, vomiting, and constipation. I recommended an exploration with the intention of relieving the vomiting and the pain due to peristaltic efforts, if no more effective treatment could be possible. The peritoneum was found studded with numerous cancerous nodules and I therefore opened a coil of gut and made an artificial anus. The operation was successful in relieving pain, but death from exhaustion took place a month later.

CASE 8.—The gentleman who performed the first operation in this case informed me that he had found an ovarian tumour so thin-walled and so deeply embedded in the broad ligament that he thought it wise to leave the tumour instead of removing it. When I opened the abdomen, nine years later, I found a multilocular thin-walled cystoma of the right ovary and corresponding disease of a similar nature on the left side. I had no difficulty in removing both completely. It is now two years since the operation, and the patient is still well, nothing abnormal being palpable in the pelvis.

In the foregoing cases I performed both operations in only two instances, the first and seventh. Death was not caused by the operation in any of these cases, and six of the patients are alive and well.

GROUP II.

In the following five cases the first operations failed to effect a cure. In each instance I performed the second operation only, and there were two deaths.

CASE 9.—The left ovary was removed from the patient in May, 1890, for the relief of inflammation accompanied by constant aching pain. After about two months the pain returned in the remaining ovary. The patient became so ill that, after consultation with the gentleman who had performed the first operation and with others, I removed the second ovary in March 1891. The patient suffered much for about a year after the operation. She then began to improve, and last spring she informed me that she only suffered from a bearing-down sensation of comparatively little consequence.

CASE 10.—This patient dated her illness from 1881, when she was much shaken and frightened by an accident. A few months later she began to suffer from profuse, frequent, and painful menstruation. In 1883 she sought advice at one of our metropolitan hospitals. Something was removed through the vagina, but with scant result. Early in 1885 an abdominal section was performed by the obstetric physician to another London hospital. After this the patient could not get about at all. A profuse red discharge from the vagina continued for three or four weeks at a time, and it was sometimes necessary to plug the vagina on several occasions. The pain was so great that injections of morphia were required

* Abstracted from the *Lancet* by request.

† Operation performed before the Medical Society of London.

‡ The possibility of metastatic disease has not been considered as a possibility, although it might be maintained that the abdominal cavity is a common source.

GROUP III.

In the remaining cases the second operation was performed on account of some complication resulting from the first operation or arising during convalescence. In this group I performed both operations in six cases. In the other seven I performed the second operation only. Five of the patients died. The first three cases in this group indicated three forms of bowel difficulty which may arise after an abdominal section.

CASE 14.—The patient when I first saw her was forty-four years of age, and had been under treatment for uterine tumours in America for eleven years. She had constant and increasing pain, which was more severe at her monthly periods. I was at first inclined to take the view which had probably been taken by others—namely, that an operation for the removal of the growths was unnecessary when the patient might shortly hope for relief by passing through the change of life. After keeping her under observation for about six months, however, I came to the conclusion that she really did suffer sufficiently to justify surgical interference. On opening the abdomen, I found that there was in each iliac region a very hard oval tumour the size of an orange, attached to the wall of the uterus by a pedicle about one and a half inches long and as thick as an ordinary cedar pencil. The growths had almost devoid of blood-supply and had become the seat of extensive degeneration, so that they were practically foreign bodies. They had created a large amount of adhesions by adhering to the surrounding abdominal wall. Without doubt these ailments

DATE 05-20-2008 BY 60322 UCBAW

After the operation was completed, the patient was placed in the prone position and the abdomen was covered with a large bandage. The patient was then moved to the ward and the following day the administration of food was resumed. The patient's condition always seemed to improve. Two weeks after the operation I ordered that feeding be continued and be persevered with for a few days. The food was not after four days the pain became very severe and was aggravated in a kind of fit. Under careful treatment the patient returned to her usual condition; and after that period she was able to take food more freely and continued to do more effect than before in moving the bowels. I found that some adhesions gave way at this time. The patient left my immediate charge a fortnight later with directions to be very careful in keeping the bowels open, to limit the diet if she became distressed. I hoped for the partial obstruction which evidently retained weight, to overcome in time by the gradual stretching of adhesions.

The patient continued to be much troubled by pain and distension. She could not take laxative medicines, or use an enema without suffering severely, and the bowels would not act spontaneously. After an interval of twenty-two months I agreed to the patient's urgent request that I should re-open the abdomen and separate the adhesions which I believed to be the cause of her trouble. On Oct. 16th, 1895, I opened the abdomen and found that the centre of the transverse colon was fixed to the back of the abdominal incision nearer to the pubes than to the umbilicus, so that this portion of the gut had a V-shape, and the acute angle at the middle of the colon was at the time of operation occupied by a scybalous mass of feces. The omentum was much adherent to the abdominal wall and also to the sigmoid flexure, which was thus fixed to the centre of the transverse colon. I separated the transverse colon from the omentum and put it in its proper place. The patient made a good recovery, and her bowel condition was much improved. She still complains of distension and pain in the right side, but Mr. Thorburn Starr, under whose observation she has been recently, tells me that the amount of pain is certainly less troublesome at times than on

CASE 15.—The next case illustrates a remote and severe effect of a pelvic operation. The patient had a double ovariotomy performed in 1882. This was followed by troublesome constipation, which became a serious affliction ten years later. She came under my care in May, 1892, when no treatment either by the rectum or by the vagina made the slightest impression on the bowels. The condition had developed very slowly. The finger in the rectum could not reach the seat of obstruction, and the masses of faeces were felt both through the vagina and through the vagina, and also by palpation of the abdomen. There was no relief to be obtained. After consulting I opened the abdomen on June 22nd, 1892, and found the whole colon enormously dilated, and the rectum was shut off from all obstruction, all

There had been no fever, but the patient was very ill, and on the 11th, the day after the operation, I failed to see the patient, and she would not open her eyes. On the 12th, at operation, however, the patient was found to be alive, the pulse being 102, and the temperature 102°F. It was obvious that the patient must be saved without further delay. The way was clear, and a large quantity of blood was removed, but death occurred about midnight. At the necropsy it was found that there had been no escape of blood into the peritoneal cavity. At the lower end of the sigmoid flexure the canal of the gut was almost completely obstructed by a mass of cicatricial tissue which had developed on the mucous surface. The lumen of the canal was reduced to the size of a cedar pencil and passed obliquely through the diseased tissues. It is now to my mind that in this case it would have been better to open and clear the bowel at the time of operation.

CASE 16.—This patient had a supra-vaginal hysterectomy performed in 1893, from which she made a good recovery. She continued well until March 22nd, 1896. On the evening of that day she ate a hearty supper, and on the following morning she was seized with severe pain in the abdomen. I was asked to see her on the 24th, when I found the pulse 72 and the temperature below 100°F. To the left of the middle line I could define a distended coil of intestine which I thought might be the sigmoid flexure. Further consultation was desired and as a consequence operation was postponed. In the meantime opium and belladonna were given, food by the mouth was withheld and the patient was nourished by nutrient enemata. Next morning the pulse was 108, the temperature was 103, and the abdomen was somewhat distended. I opened the peritoneal cavity and found a coil of small gut strangulated and sloughing. It had been tightly constricted by a band of adhesion which was very strong although not thicker than a piece of No 3 Chinese silk. I washed out the peritoneal cavity and made an artificial anus; but diffuse septic peritonitis already existed, and the patient died about 10 o'clock in the evening of the day of operation. Surgical treatment cannot be employed too soon for the condition which existed here, but it is not always easy to decide beforehand when to operate. Cases of obstruction by band if promptly treated should give as good results as the operation for strangulated hernia. Unfortunately, the diagnosis is more difficult and the initial treatment is too often a purgative.

In the next two cases, Nos. 17 and 18, the second operation was required on account of a hernia in the scar of the first.

CASE 19.—Though the peritoneum was not opened this case is included in the series because the kidney is an abdominal organ. The patient had lost a great deal of pus from the right kidney for five years before I saw her. I drained the organ, giving great relief, but four weeks later an obstruction in the left ureter necessitated a left nephrectomy. The patient died three days after the second operation.

CASE 20.—In this case an apparently adherent dermoid ovarian tumour was removed on 11th June 1896, and the patient's condition gave no trouble or anxiety for a fort-

night. The patient was very ill, and on the 11th, the day after the operation, I failed to see the patient, and she would not open her eyes. On the 12th, at operation, however, the patient was found to be alive, the pulse being 102, and the temperature 102°F. It was obvious that the patient must be saved without further delay. The way was clear, and a large quantity of blood was removed, but death occurred about midnight. At the necropsy it was found that there had been no escape of blood into the peritoneal cavity. At the lower end of the sigmoid flexure the canal of the gut was almost completely obstructed by a mass of cicatricial tissue which had developed on the mucous surface. The lumen of the canal was reduced to the size of a cedar pencil and passed obliquely through the diseased tissues. It is now to my mind that in this case it would have been better to open and clear the bowel at the time of operation.

The patient was confined at home, and on the 11th, the day after the operation, I failed to see the patient, and she would not open her eyes. On the 12th, at operation, however, the patient was found to be alive, the pulse being 102, and the temperature 102°F. It was obvious that the patient must be saved without further delay. The way was clear, and a large quantity of blood was removed, but death occurred about midnight. At the necropsy it was found that there had been no escape of blood into the peritoneal cavity. At the lower end of the sigmoid flexure the canal of the gut was almost completely obstructed by a mass of cicatricial tissue which had developed on the mucous surface. The lumen of the canal was reduced to the size of a cedar pencil and passed obliquely through the diseased tissues. It is now to my mind that in this case it would have been better to open and clear the bowel at the time of operation.

On July the twenty-second day after the operation, some urine was passed containing about half its bulk of pus. After this the patient's condition improved somewhat and the urine again became clear and contained only a trace of albumin. There was no trouble from the bowels. The lower abdomen was soft and flaccid, and no tenderness or tenderness was detected in the pelvis by bimanual examination. The left kidney remained very tender. On July 6th, the twenty-sixth day after the operation, the patient's condition was again worse; the left kidney was very hard and could not be touched without causing severe pain; the temperature rose to 105, and the pulse, which had been steady, about 84 to the minute, rose above 100. The patient became drowsy and indifferent, and I expressed the opinion that she would die if an opening were not made into the left kidney. On 7th July, in consultation with Sir DOUGLAS POWELL and Mr COKER, of Uxbridge-road, it was agreed that the kidney should be opened, and this was done immediately. The kidney was not less than nine inches long, and broad in proportion. On tapping it with a trocar and cannula I drew off some red fluid but no pus. I therefore made an incision into the pelvis, but still got no pus. On inserting my finger I found that the calices were much enlarged, and I divided several septa, pushing my finger into the kidney in all directions, but gaining no further information as to the cause of mischief. The parts outside the kidney were quite normal. I inserted a drainage tube and closed the wound. The patient was very feeble for a couple of days and the temperature remained high, but after 9th July the course of convalescence was one of steady improvement. Later it was discovered that these attacks yielded promptly to purgation, and Mr COKER suggested that free purgation might have obviated the necessity for the second operation. This is just possible, although I hardly think it likely. It did not occur to any of us to treat the case in this way at the time of serious danger, and the bowels were then being frequently moved without difficulty. It should further be considered that although I discovered nothing but a much dilated kidney at my second operation, I must certainly have altered the relations of its calices to each other by my manipulations, and that in this way I may have broken down some obstruction to the exit of urine. I am inclined to think that this patient had suffered from pressure of the tumour on her ureters, especially the left, for many months before operation, that the kidney was distended accordingly, and that when she got up after lying on her back for a fortnight the left kidney was, filled over and formed a valve-like obstruction, which was closed by the pressure of the fluid within the kidney, and which she and I did not find till the kidney was opened. At the second operation I probably removed some of the calices, and thus made a

the patient was very feeble, but on the fourth day after hysterectomy the bowels had acted freely, the sloughing pedicle seemed to be separating nicely, the patient enjoyed her food, and I thought all would be well with her. On this day I made a note that the wound above the pedicle was free from all signs of irritation, and I removed all the sutures except those next the sloughing pedicle. The following night the patient was restless and uncomfortable. On the twelfth day after the operation I found that about an inch of the upper part of the incision had yielded, exposing the omentum. There was no sign of adhesion or other inflammatory reaction. I carefully cleaned and re-closed the opening by three sutures, but the patient gradually sank and died thirty-six hours later. At the necropsy there was no evidence of inflammation in the abdomen except some injection of peritoneum behind the seat of rupture of the wound. There was much congestion of the lungs, and all the tissues were very anemic. I have seen a considerable number of cases of rupture of the abdominal wound due to a sudden strain, as from retching or coughing after the sutures have been removed, but I have never seen any other than this, in which there was no attempt at union of the exposed viscera to the edges of the incision, or any in which a fatal issue has resulted from the accident.

CASE 22.—This patient was a woman, aged forty years. There had been a uterine discharge for six years, which had constantly increased and had been very offensive for about two years. The uterus had been curetted by one of my colleagues in February 1896, but a microscopic examination of the scrapings had not indicated that the disease was malignant. After a time, however, a clinical diagnosis of malignancy was made, and I was asked to remove the uterus. When I saw the patient her womb was slightly enlarged and was discharging great quantities of offensive matter, and as a consequence she was extremely anemic. Removal of the uterus seemed possible, and the patient, although made fully aware of the serious nature of operative treatment, was most anxious to take the risk. My colleagues with whom I consulted thought an operation was justified as affording the only chance of relief. I therefore agreed to open the abdomen and to perform hysterectomy if the disease seemed confined to the womb. I performed this operation, but cancerous disease had almost destroyed the whole circumference of the uterus well up the ligaments. In the evening, although the patient was very feeble, her condition, both physically and mentally, was satisfactory. Next day she appeared to be doing well in every way. She had passed the evening of

well in the evening patient thought that a catheter had been put into her bladder, and when I went to see her I found that the catheter was gone, and that she had been voiding. The temperature had risen to 101° F. in the axilla, but had come down to 99° by 10 A.M. The pulse, however, was extremely feeble, and then to 120, and 130. In the afternoon the heart failed still more. About 8 P.M. however, the patient suddenly collapsed, the temperature falling to 97° and the pulse becoming spasmodic. About 10 P.M. her a little later she was evidently moribund, and sensible, and the condition seemed to me to indicate the effects of hemorrhage so closely that, when I had ascertained that there was no escape of blood from the vagina, I determined to re-open the abdomen. The patient was so ill that no harm could result if there was no hemorrhage, and it did not seem right that I should leave the question of the possibility of the existence of hemorrhage undecided. The second operation was a very trivial one—merely the removal of a few sutures and the loosening of the finger—but it might have been a very important procedure, as in Case 24, and it brings the case within the title of this paper. The patient died an hour later. At the necropsy some coils of intestine were found to be adherent in the pelvis, and there was some turbid serum there also, but no blood. It was undoubtedly an error of judgment to yield to this patient's desire to be operated on, but I have always been guided in this question by the view that if there be any doubt as to the course to be adopted, that is, if I think there is any chance at all of benefit being derived from an operation, the patient should be allowed to decide for or against this course if he or she has been made clearly to understand the risks involved.

In the last four cases in my list I was fortunate in being able to perform successful operations in emergencies occurring in the practices of others.

CASE 23.—In this case the operations were the same as in Case 21—namely, a hysterectomy and a re-sewing of a ruptured incision on the eleventh day. But in this case the patient was a strong woman; her wound gave way suddenly during the night, and when I examined it some hours later I found the protruding bowel firmly adherent to the divided edges of the incision. I cleaned the parts, returned the viscera, and sewed up the wound, which did not give any further trouble.

CASE 24.—I was asked to see a patient about two hours after a hysterectomy had been performed. She had suddenly become very pale and faint whilst in the act of retching. When I saw her she had every appearance of severe hemorrhage. As the gentleman who had operated was not at hand I opened the abdomen, found that the cavity was full of blood, and that the right broad ligament had slipped completely from its ligament. I secured the divided broad ligament and removed large quantities of blood, but I did not wash out the abdominal cavity because healthy blood-clot is not likely to be harm. A glass drainage tube was placed in the pouch of Douglas. It was doubtful for many hours, indeed for days, whether the patient would survive; but she gradually rallied and made a perfect, though slow, recovery. She was alive and well five years after the operation.

CASE 25.—In this case the inverted fundus of the

It is a disease of the female sex, and is commoner in young women than in any other age. It is found to be a general, but not independently associated, disease. It is supposed that it is commoner in warm climates than has been a previous endemism. One of the most striking observations is that the patients are generally in a low state of health; it is not the robust, muscular, healthy sort of women who are the victims of trouble; it is the flabby and ill-

The hemorrhage which comes from underneath the placenta may be so small as to remain located under the chorion, and beyond detaching a few of the chorionic villi, and indirectly doing a little damage to the circulation of the fetus, and consequently retarding the aëration of its blood, it does not do much harm. It is often recognized at full term by a patch of adherent placenta. But generally the blood makes its way from underneath the placenta between the chorion and decidua and shows itself externally.

A more serious variety is where it becomes *concealed*, that is to say, where it has stripped up the placenta and a good deal of membrane, but fails to quite reach the internal os. These two forms of hæmorrhage may co-exist. The prognosis of the former is not serious, but the concealed variety, if at all profuse, is a very grave condition indeed.

The symptoms of the ordinary accidental hemorrhage, where blood is showing externally, is simply external hemorrhage *plus* the fact that the woman is pregnant and that perhaps some attempt is being made at labour. In the concealed form, however, the symptoms and physical signs are first those of shock and evidences of internal hemorrhage or of hemorrhage which is not explained by the amount of hemorrhage which is showing externally. Then there is a great deal of pain, not intermittent, like true labour "pains," but continuous pains, pains of tension, due to the sudden over-distension of the uterus with one to three quarts of blood which has been infused into it. When one comes to palpate the abdomen, the legs are found drawn up, the abdomen is very hard and tender, the uterus feels very hard, perhaps irregular in shape (bulging in some places more than in another), the outline of the uterus is obscured, no movements can be detected, and the fetal heart cannot be heard. And when one comes to examine per vaginam the head, which may have been protruding on a previous examination, may be pushed out at the very end and cannot be recognised by the examiner's fingers.

Postnatal hemorrhage has to be diagnosed mainly from grossly bloody stools, and practically the diagnosis can only be made when you can put your finger down on the bleeding site, and make sure that the placenta is the source.

1. The first step in the process is to identify the problem. This involves gathering information about the situation and the people involved. It is important to understand the context and the impact of the problem on the organization and its stakeholders.

[illegible]

The prognosis of most of these cases of accidental hæmorrhage is good if labour pains are present, but in the concealed variety it is bad. It is said that 80 per cent. of the mothers die and 90 per cent. of the children. The treatment of the ordinary form of accidental hæmorrhage, unless it is a very marked case of hæmorrhage, is to palliate—keep the patient quiet. It is a mistake, and you are sure there is no obstruction, give ergot to try to induce uterine contractions, and at the same time put a binder on to apply equal pressure to the uterus. If hæmorrhage goes on, it is much better, especially after the twenty-eighth week, when the child is viable, to palliate no longer, but to rupture the membranes. The membranes are ruptured by the finger, and made into a saw, or by a probe passed up along the finger. The almost immediate result is to induce the uterus contract and retract, and so to close the uterine sinuses, and then the hæmorrhage after this procedure almost always stops, and labour can be practically left to come on as it will.

In the concealed variety, however, mere rupture of the membrane does not bring on uterine contractions, because the uterus is over-distended and is in a state of shock, and practically primary uterine inertia is present. It is therefore advisable, as the hemorrhage is going on, to try to release some of it; and you can generally do this after digital dilatation of the cervix, by stripping away some of the membranes on one or other side, and especially if you like. Very often you can thus free the neck of the blood-clot, which is often just above the internal os. This evacuation will give an opportunity for the uterus to contract down. If you find the hemorrhage does not cease, but becomes greater and more profuse, it is much better to rupture the membrane and bring on labor as rapidly as

that it is impossible to see. That is, however, not
HALL'S idea. He merely believed that it was that the
ovum was not always attached early, where the uterine
muscle is thickest. He supposed that that is the explana-
tion why the placenta *previa* which may be implanted
in the cervix, does not become detached on the various
movements of the tube habitually, but it finds its way into
the cervix, and, especially after the menstrual period,
when there is no epithelium on the surface, becomes located
somewhere on its lining membrane. He states that
the reason of *placenta previa* is that the ovum has not
found any detached patch until it reaches the lower zone,
where perhaps some recent desquamative endometritis has
been present. That has not been accepted by many
writers; in fact, it is too recent a statement to have
received much criticism. It rather bears out LAWSON
TARR's idea of the cause of tubal gestation being due to
graveles saplingitis, where the epithelium would be de-
tached. Another theory, which I think will turn out to
be the right one, is that advanced by HOFFMEIER. He
believes that the *placenta previa* is due to the develop-
ment of the placenta within the decidua reflexa at the
lower zone of the uterus. The ovum might have been
implanted at the normal fundal end of the uterus, and yet
the placenta had been developed from persistent chorionic
villi at the other end. That has been accepted by a great
many Continental writers MARTIN, ALFENBACH, and
OLSHAUSEN amongst others.

Neither do we know for certain why hæmorrhage should so often follow this low insertion of the placenta. There are many theories about it. Its exciting cause may be a blow, just as in accidental hæmorrhage. But the probability is that during the later months of pregnancy, long before any definite signs of labour come on, there is a distension and gradual gathering up of the lower zone into the main body of the uterus, and the placenta, being inelastic, is stripped off here and there, and therefore hæmorrhage results. Another theory, which has a great many adherents, is that the placenta, especially in the later months, grows more rapidly than the lower zone, and practically grows off the lower zone of the uterus, and the uterus becomes then detached from the placenta. In any case, however, the hæmorrhage is maternal, coming from the uterine sinuses, so that the child does not die from loss of blood *via* the fetal placenta, but from *æmphyxia*.

The *symptoms* of placenta previa are practically hæmorrhage in the later months of pregnancy. This hæmorrhage is not concealed, but is external, and can be diagnosed at once, and solely by passing the finger through the cervix; so that if one has a case of serious hæmorrhage in the later months of pregnancy, in order to arrive at a diagnosis one must, as a step to diagnosis as well as treatment, get the finger through the cervix. That can be generally done by a little gentle digital pressure, without any dilating by bougies, especially in multipara. Occasionally the presence of the placenta can be recognized by vaginal palpation, abnormal ballotement, &c., but these negative signs are not very reliable. The difficulty in laying down anything like definite treatment is the fact that in two cases one can be treated on quite the same routine principle; as I want only to speak of the outline

of treatment. Some cases die and without being treated at all, but these are the cases where the hemorrhage is slight and the labor is painless. In each case the prevailing part is forced down through the internal os and compressed the placenta against the bleeding site underneath it, and we arrest the hemorrhage. One often meets with cases of ante-partum hemorrhage which have not been seen sufficiently early to make an ante-partum diagnosis, and yet one finds afterwards that the only hole in the membrane is adjacent to the edge of the placenta, instead of being practically at the opposite pole, showing it was a case of marginal or partial placenta previa.

I did not mention the classes into which placenta prævia is divided. The most serious of all is the complete placenta prævia, where it is central, completely covering the internal os. Here the whole placenta is perhaps nine inches across instead of seven, and covers all the lower zone and part of the middle zone of the uterus. Then there is the partial placenta prævia, where it overlaps the os to a certain extent, but the membranes can be felt as well as the placenta. And then there is the marginal placenta prævia, where the membrane comes down to the os and can be felt, or where, if we do not examine until labour has begun, it feels like a fleshy tongue coming down into the cervix. Spontaneous deliveries would more often ensue were it not the case that in cases of placenta prævia malpresentations are more common, because the head does not adapt itself so well to the lower, cupped or otherwise altered lower zone of the uterus. The tendency, therefore, is to get a shoulder presentation which does not come down into the cervix, and does not compress the parts as a vertex or breech or thigh would do. Now, suppose one has a case of hæmorrhage, and is satisfied that it is a case of placenta prævia by having passed the finger through the cervix. We will suppose that gestation has not progressed twenty-eight weeks, and that the child is not likely to be viable. In that case, if it is placenta prævia at all, it generally means that the placenta is a central implantation. The more centrally the placenta is attached to the lower zone the earlier does the hæmorrhage occur. It is obvious that it may be so, for it is attached over a larger surface of the lower zone. Therefore there is no particular reason why you should not bring on labour at once, and it is very much safer to do so. In cases occurring after the twenty-eighth week if the child is dead there is no necessity to wait, and nothing can be gained by it. If it is alive, which you can perhaps detect by hearing the foetal heart or by movements, I still think that if the hæmorrhage is at all severe it is much better to interfere at once so as to try and keep that child alive; otherwise the child is almost sure to die. It follows, therefore, that in any case of placenta prævia at any period, when one has once made the diagnosis, one ought, if the hæmorrhage is at all severe or has recurred, to consider that that woman, if allowed to go on with her pregnancy is doing so at the risk of her life, and it is much better to bring on labour at once.

As to the methods of treatment, I think the first thing to do when one gets a case of placenta previa, where the diagnosis is sure, is to strip off a bit of the placenta from the lower zone by passing the finger through the internal

Since this time, most surgeons have conceded that although the etiology of cancer remains as great a mystery as ever, its history indisputably points to its local origin. The mammary gland has been cited as an example: in which there is first a swelling, in the beginning painless and insensible; which, after a varying period of time, becomes the seat of lancinating pain and tumefaction extending into the axilla; and the pain becomes more accentuated. This is about the stage when the patient becomes aware that something serious has seized on her. The very thought of "cancer" racks her soul, and mental agony begins, for she knows it means her death knell, her spirit is crushed and a smiting blow has been struck on the vital processes. As one overwhelmed with secret grief, her powers soon show signs of giving way, the appetite fails, her nights are sleepless, and she is incessantly haunted with the thought that her doom is sealed; fated and condemned to the agonies of this dreadful scourge.

Now the 3rd stage is reached, her nutritive processes are profoundly altered, the flesh wastes and the spirit sinks, her strength fails. Now or possibly before this, a propagation or generalization of the disease begins. But we must not confound propagation with generalization in cancer, for generalization may kill even before propagation has begun. Now the budding, growing, enlarging crop of new elements bursts through the integuments and hemorrhage with stinging pain and a copious discharge of ichorous fluid steadily saps and exhausts the supporting powers of nature.

The new elements slough and a horrible gangrenous odor is present. Now we may have pus absorption, putrid infection, a general dissemination, or a metastatic spread of the malady.

DEATHENS AS A CONDITION PRECEDING LOCAL LESION.

Now let us turn to the views of LABET and BROCA among the moderns and contrast their attitude with the "Localists."

BROCA declares of the diathesis:—"that it is impossible to foresee, or guard against it; it cannot be escaped from and is inaccessible to treatment. It is an index of the constitution, which precedes any local changes."

Therefore, according to him, the evolution of cancer is first a pre-existing diathesis, provoking the organic change. The secondary changes in the growth lead to primary infection, and finally, this infection tends to metastasis and death.

The question of cancer has been generally admitted in France, Italy, and Germany since ...

...the history of cancer surgery to some extent, and was also mentioned by PACHA, ... On the contrary from the ... the time of HIPPOCRATES, CANCER ... until the time of the 16th ... was regarded as primarily constitutional, ... not universally admitted.

He answers, No! But if says he I supposed there be examined in like manner, can its character be definitely recognized? He answers in the affirmative although he insists that there are discrepancies in which the microscope alone could not be depended on, as he always recognizes a clinical as well as a histological distinction. He says by this combination of the clinical features with the anatomical elements, he has in most cases been able to determine with certainty the probable character of a tumor or ulcer. Labet, *Traité Malade, Pratique des Malades Cancerreux*.

HENOCQ long since maintained that predisposition was a leading factor in malignancy; and that the local mutations of tissue were stimulated into activity by various physiological and psychical states. HENOCQ (*Dictionnaire de med. Hypothèse des matières cancéreuses*). BOUTILLARD after considering in detail the numerous theories on causation, declared that the initial factors of cancer are absolutely unknown. PÉRYOLLE and BROUSSIN deny both diathesis and predisposition. *Etude sur le cancer*. BICHAT in his time was a strong advocate of the local origin of cancer *Oeuvres chirurg.* T. III p. 421.

VELPEAU regarded malignant diseases as primarily local in origin and capable of radical cure by surgery. This is a proof that our modern views on operative cure are by no means recent. But ROGER whose studies on this phase of the subject were most extensive, denied the possibility of cure of cancer by surgery, alleging that the cases cured were not genuine.

ROBERT PARK is strongly inclined to believe in the infectious origin of malignant disease, and in a recent contribution in the *Annals of Surgery* sets forth at considerable length his reasons for taking this position; but his theories are lacking the confirmation of scientific proof and hence must be regarded as only speculative.

ROGER WILLIAM who has presented us with the most complete treatise on cancer that we have in English, gives us no clue as to the direct systemic cause of cancer, but makes the extraordinary and melancholy statement that the malady is enormously on the increase; that it works its great ravages in those who live regular temperate lives, and that the libertine and the dissipated usually escape it.—*A Treatise on Cancer*.

THE CONSTITUTIONAL ELEMENT.

My out-experience has been that of all influences the constitutional takes first place in the rate of causation in cancer, and that at last while surgery comes in to relieve the victim of his agony and give him what Mr. JAMES CHIESS of Edinburgh so appropriately designates "mental rest," it can only deal with surface indications, or as JACOBS puts it, in uterine cancer it can be regarded only as a palliative measure.—*Gen. Heb.* '98

The conquest over this scourge can now or never be complete, until internal remedies are discovered which will destroy the lethal elements in operation in the blood. Heredity, grief, and disappointments, disordered physiological states all play their shares. The younger the subject the more destructive the lesion.

It appears that cancer is strikingly a disease of advanced civilization and works its greatest havoc among those who partake the most freely of flesh food. It has been a question whether it is most frequent among the single or married. It is certainly one of the most common afflictions of senility among females.

THE CANCER HISTORY, SPERMATOCYSTS AND PIGMENT IN CANCER

Biological embryology we are forced back on physical phenomena to aid us and guide us in the recognition and prognosis of cancerous disease. Sight and touch enable us to decide on the character of various neoplasms, but the nose never fails to stamp the character of a growth after the ulcerative stage begins, for the peculiar foul ichor of cancer has no possible counterpart and can never be mistaken. But some cancers kill before they ulcerate, and visceral cancer except of the hollow organs may spread far and wide before gangrene begins.

Peripheral cancer seizing on the epithelial stratum of the integuments or the orifices of the mucous membranes presents such a regular series of sequelae and such distinctive and subjective features as are not liable to mislead the average observer though error is possible in certain atypical or undeveloped cases. Let us not overlook the many similar characters which epithelial proliferation may present in the anorectal outlet, the bladder, the prostate, the lips, the tongue, the pharynx and larynx, nor the occasional similarity between surface tuberculosis, syphilis and cancer.

Tuberculosis or syphilis we may cure by local and constitutional remedies, true cancer probably never.

It would, therefore, under an erroneous diagnosis, be a most calamitous affair if we subjected our patient to the sacrifice of an organ that might be spared. Let no one deceive himself into a belief that the microscope will always remove every possible doubt in all cases, for it cannot. It can define the histological chaos, but the bearing of this on tissue change it cannot foretell. Hence why the clinical features must be scrutinised and analyzed with great caution under all circumstances.

Notwithstanding the claim, that the spread of cancer is on the increase it is my opinion that it is not, but that since the verdict of the microscope is being so generally accepted without question, a great many cases of syphilis and tuberculosis are being entered on the lists as malignant diseases.

Since the propaganda of the early and wide incision has been adopted as a prophylactic, there can be little question about it.

Certainly, I have witnessed the ablation of lesions, stamped as "Cancers" which presented some of the genuine features of the malady to me, and cases have been under my care which had been pronounced malignant, that turned out innocent.

Visceral Cancer is quite invariably insidious in its advent, as very often the first intimation we have of it is when it has induced stenosis, perforated a tubular passage or made its way out to a serous surface.

This is most notably the case when it seizes on the cephalic end of the pylorus. In cancer of the lower passages hæmorrhage appears in its advanced stages with the excretions.

It was thought that the ablation of peripheral cancer was often followed by metastatic invasion of the viscera.

In doubtful cases of internal cancer the cachexia is one of the most invariable signs of its presence. In this class of cases it is evident that surgery can do nothing or little other than remove mechanical impediments. Surgery has accomplished marvels here in the way of securing temporary relief and renewed lease of health, as the tissues being highly vascular are hyperplastic and undergo repair with singular rapidity and perfection.

A MIRROR OF PRACTICE

REMARKABLE UNDERSTANDING UNION OF A FRACTURED THIGH BONE IN AN OLD WOMAN OF SIXTYTHREE

By JAMES R. WALLACE, M.D., F.R.C.S.
Calcutta.

Mrs. S., an Irish lady, sixty-three years of age, of splendid physique, who has lived in Calcutta for over thirty years, and by the way is the mother of three British officers in the Indian Army, slipped in her bath-room on Christmas Eve 1897, and fell heavily across the one-foot-dam so frequently seen in English houses in this country. She struck herself across the middle of the right thigh and immediately felt severe pain in the part, was unable to raise herself and had to be carried to her bedroom. Not suspecting that her leg was broken, she lay in bed suffering great pain. The extensive swelling and discoloration of the thigh and hip alarmed her and I was summoned to attend her at noon on the 26th December, two days after the injury. I found Mrs. S. in great pain, unable to move, with pillows propped behind her in a half sitting posture, and the lower half of her right thigh and leg lying almost at a right angle to the upper half of the thigh. There was great swelling of the parts, the ecchymosis, which covered the whole limb and extended backwards into the hip, was not only perfectly black, but the skin showed signs of blistering, from the extensive superficial extravasation of blood. The limb seemed bordering on a gangrenous condition, but was warm, free from smell, and pulsation could be felt in both the common femoral and the popliteal. There was also a feeling of healthy warmth in the foot of the injured limb. The patient seemed much exhausted, so after administering a little brandy and water, I gave her a few whiffs of chloroform, straightened the broken limb, swathed it in cotton wool and bandages, and after fixing a temporary extension weight to the ankle and settling the limb between two sand-bags, I advised constant nourishment and stimulation and watchful care for a few days before putting the leg into splints. I gave a serious prognosis, as from all appearances, gangrene seemed imminent. For three days the broken bone was kept in position with sand-bags, and during this period the enormous swelling subsided gradually, though the extravasation discoloration lost none of its suspiciously grave appearances, except that the sanious bullæ had collapsed, and the cuticle was dried and shrunken. This was a favorable sign and I therefore gave a guarded but fairly satisfactory prognosis. Extension of the limb was now accomplished by means of an 8 lb weight and a pulley arrangement over the foot of the bed. By the tenth day the swelling was almost entirely gone, the ecchymosis had altered in color, and though there was no sign of union between the injured fragments of the femur, both ends being still freely moveable. The limb was in perfect position, there was very little pain, except on pressure or movement and there was a complete absence of muscular rigidity or spasm. The thigh and leg were now fixed to a Linton's long splint and the extension apparatus readjusted. After three weeks this splint was removed and the thigh was put into a plaster of Paris encoisement; the extension was continued. After four weeks the plaster casing

was taken off the foot was bound somewhat tightly with bandage. Extension was stopped and the patient was allowed to go about on crutches. The appearance of the thigh at the seat of fracture was all that could be desired. There was some degree of bulging, but the callous nodosity was comparatively small, though apparently very dense and hard. There was little or no limp when I saw the patient six months later, and only about half an inch of shortening of the limb.

The most remarkable features about this case, which render its publication surgically interesting, are—

(1) The old age of the patient—63—and her safe recovery from the intensely threatening traumatic conditions that made gangrene imminent.

(2) The perfect recovery of the use of her limb with scarcely any apparent shortening in one so advanced in years.

GLOBULAR FOREIGN BODY IN THE OESOPHAGUS REMOVAL BY DIGITAL MANIPULATION

By ASSISTANT SURGEON J. C. GILLMAN, I.S.A. Lond
Civil Medical Officer, Puri District

NABINI, an Oorya female *et* 28, presented herself at the Puri Pilgrim Hospital on the morning of the 15th October, with a history that on the previous day at about 11 o'clock while playing with her child, she put a rather large sized beetul nut into her mouth with the object of letting the child see it disappear, when to her surprise it went down the pharynx and lodged in the oesophagus behind the cricoid cartilage from whence it would neither come up nor go down.

The patient appeared alarmed about herself, countenance anxious, eyes staring respiration somewhat embarrassed, frequent attempts were made to vomit but without avail, mouth filled with rosy and frothy saliva which could not be swallowed, water and other liquids were likewise rejected.

On my arrival at the hospital I was informed about the case and after satisfying myself that the foreign body was neither in the larynx or trachea, I endeavoured to introduce the tube of the stomach pump but could not pass it more than 8 inches beyond the teeth. A No 12 catheter was tried with no better success. Externally the nut could be felt distinctly through the skin, but could not be moved, manipulation under chloroform failed to shift it.

As the symptoms were not urgent, I resolved to see what time would do before resorting to oesophagotomy, and in the meanwhile ordered a hypodermic injection of morphia, nutrient enemata and perfect rest.

The next morning the symptoms were much the same, so I procured the husband's consent to an operation should further endeavours fail to remove the nut. I passed the forefinger of my left hand down the oesophagus as a guide with a long curved forceps but could not grasp it. After applying a 4 per cent cocaine solution with a probing sponge, I proceeded to use gentle and firm upward pressure externally with both index fingers, this caused the patient to struggle slightly, when with increased pressure I succeeded in forcing the beetul nut into the mouth.

This case shows that when there is a suspicion of the presence of a globular foreign body in the oesophagus which is likely in time to become smooth and covered with mucus, we should wait for sometime before resorting to oesophagotomy, provided the symptoms are not urgent; even though at first we may not meet with success.

A COPY OF PNEUMONIC PLAGUE SIMULATING ACUTE BRONCHITIS.

By HAN DEVI SHARMA, L.T.M.S.,

Special Plague Officer, Abu Road, Rajputana.

GANGARAM son of TULIRAM aged about 45 years, resident of Rohara in Sirohee territory, arriving from Bombay, where he was a peon in the Custom Office, was detained here for observation as he was suffering from cough and slight fever, on the 17th October 1898. His brother died of plague in Bombay and he was coming home to perform the obsequies. In the evening his temperature rose to 103.4° F after chills and rigors. He was at once isolated with all his effects and diaphoretics and expectorant mixture prescribed. At night he was a little delirious.

On the 18th instant his morning temperature was 100.6° F, but his cough was troublesome, he expectorated pure bright blood at frequent intervals. On auscultation, tubular breathing could be heard with dullness of both lungs. He had 4 loose stools before 10 A.M.—Salol in viii grs. doses had the desired effect after the third dose. He was very feeble and prostrated. His tongue was covered with coffee coloured fur, there was no diminution in the hæmoptysis. In the evening his temperature rose to 104.6° F, was delirious and comatose. The same mixture with milk and tea continued. The prostration became worse and worse.

On the 19th instant his temperature registered 103.2° F, pulse small and slow, abdominal breathing. The hæmoptytic blood was portwine colour but was unmingled with mucus. He was listless, apathetic and face dusky, tongue furred and blood stained, conjunctiva suffused, great prostration and aphania. The stimulant mixture with hot tea and milk given every third hour. After 2 P.M. the condition became worse and sudden syncope setting in he died at 6.30 P.M.

The precautionary measures taken after his death were—His brother who had been here from Rohara to see him was isolated with his personal effects the same evening. The hut and the clothing &c of the deceased were burnt to ashes, phenyls were freely poured around the camp. The corpse was cremated and the bearers isolated for 10 hours.

From the history of the case and from my past experiences and observations, I believe that the man died of "primary plague pneumonia."

His brother who attended him for the last 50 hours will be detained for 10 days observation, and every precautionary measure conceivable is being adopted to neutralize the infection.

The above case is interesting for the following reasons—His brother died of plague in Bombay on the 9th inst and he left for home on the 15th inst. He was detained at Anand Observation camp for 6 hours and his personal effects were disinfected. He arrived at Abu Road in apparent health on the morning of the 17th inst. and the same evening he was attacked with fever and bronchitis and died after 49 hours illness. The disinfection pass, No. 412 dated Anand the 16th October 1898, is in my possession.

Indian Medical Record.

1st November 1891.

GOVERNMENT SUPPORT TO INDIAN MEDICAL JOURNALS. ANOTHER CROSS INCURSION IN BENGAL.

THE question of supporting Indian medical journals from the tax-payer's money will probably come prominently before the public very shortly. We have referred over and over again to the favoritism of the Government in maintaining an unjust partiality towards the *Indian Medical Gazette*, so that our advocacy for the abolition of this hateful system is not a new one. We have attacked the policy of the Government and not the *Gazette*. The remarks we made in our last issue have been construed by some bilious fault-finders into a libellous attack on the *Indian Medical Gazette*. We do not put ourselves up as being specially versed in Law, but we know enough to pilot ourselves clear of any of the shoals and quicksands of the perilsome enactments which deal with libellously writing journalists. We libel nobody. We mean to libel nobody, and we determinedly hope we shall never libel anybody. But we shall voice our sentiments fearlessly in the exposure of wrong-doing, and we shall never be backward in letting down the full glare of journalistic daylight into every creek and corner of all such crooked policies which tend to the perpetuation of monopolies that crush out every effort of honest, independent enterprise. This is clearly our duty, and we mean to do it, even at the risk of being dragged into a Police Court. For our own part we are so sure that we have not been guilty of the faintest infringement of the law of libel, that we would rather welcome a public enquiry into what we may pointedly style a "godfathering of medical journalism in forma pauperis," by which we mean nothing more nor less than this, namely, that the Government, imbued with the idea that a medical journal could not exist twenty-five years ago without State aid, decided to maintain and to support one by a subsidy from the revenues of the country, and we hold that no such aid is needed to-day by any medical journal that has the support of the medical profession, and as there are medical journals competing in the field, the time has come for the withdrawal of such paternal anxiety and wet-nursing on the part of the State.

Now as the whole subject of such State protection and partiality is likely to gain wide publicity and interest, we venture to place the whole matter before our readers and the public, as we have dealt with it from the beginning up to the present time, though we must apologise for reproducing our former articles, our only excuse being, to leave out no link in the chain of evidence as to our dealings in this matter.

Our first article appeared in June 1891, and was as follows:—

"We believe in the old Scotch maxim that 'fair play is bonny play,' and learning from good and reliable authority here in London, that the Indian Government pays a handsome monthly subsidy to the proprietors of

the *Indian Medical Gazette*, we are about to speak of it with candor and impartiality, and to demand a return of which justice it has a distinct obligation by returning an equal share of support for this Journal as is given to our contemporary. We are perfectly prepared to carry on this Journal without Government support, and to give the fullest sway to the honest and honorable practice of 'live and let live'; but we must claim a 'PATRONS AND NO FAVOR.' If, when there was no medical journal in this country, the Indian Government very rightly considered its patronage and support were necessary, and might with justice be given to private enterprise, to encourage the undertaking of establishing a journal in the interests of Medical Science, the time has, we believe, now come, when with healthy and vigorous competition, such enterprises might either be left to maintain themselves and Government support be entirely withdrawn, so as to give an equal chance to all competitors in the arena of medical periodical literature, or else the Government should equally distribute its favors. We maintain, as representing independent and distinctly private enterprise, that we have a perfect right to an existence, unhampered by the crushing and fatal influence of any one-sided partiality or favoritism, and it is our purpose to test this question to its fullest possible and legitimate extent. We have, as an initial measure, forwarded the following letter to the Chief Secretary to H. M.'s Indian Government, Simla, dated 14, Farnival Street, London, 29th April 1891:—

"SIR,—As I am about to apply to H. M.'s Indian Government for similar support as it has graciously accorded to the *Indian Medical Gazette*, for this Journal, may I beg the favor of being informed as to the number of copies of the *Indian Medical Gazette* for which the Indian Government subscribes monthly. Two copies of the *Indian Medical Record* are forwarded monthly to the Indian Government. Soliciting an early reply to my London address."

I am, dear Sir, Yours obediently,

JAMES R. WALLACE, Editor, *Indian Medical Record*."

In our September 1891 number we published the following remarks and letter:—

"In our article on this subject in our June issue, we published the letter we forwarded to the Indian Government, seeking for information as to the support the Government accords to the *Indian Medical Gazette*. The following reply has been received from the Under-Secretary to the Government of India, dated 17th June 1891:—

"In reply to your letter dated the 29th April last, I am directed to say that the Government of India subscribe for only one copy of the *Indian Medical Gazette*."

"I am to explain that, as the charge for the purchase of, or subscriptions for books, is now borne by Provincial Revenues, the Government of India do not ordinarily subscribe for more copies of any work than are needed to meet their own requirements. It is usual for the Local Governments to decide as to the number of copies of a publication which is required for their own use or for distribution to local officers."

"It is clear from the above that the support of the Government of India is limited to but one copy of the *Gazette*. The term 'Provincial Revenues' indicates the region from which 'the handsome monthly subsidy to the proprietors of the *Indian Medical Gazette*,' which we referred to, is derived, and we will now extend our respectful enquiries in that direction, and hope either to bring about a fair and equal distribution of 'the loaves and fishes,' or secure 'fair and free trade' in the arena of literary dealing. We simply desire to see equal monopolies established. In this we have no personal ill-will against any one, and we protest emphatically against any

efforts being thus concentrated. Some kind friend has written us that our inquiries in this direction have stirred up strife in certain quarters, and that a firm resolve has been made to crush us. It is a compliment to know we are worthy of such friendly designs. However, we have known of such threats being put into active operation before now against thriving institutions, and every secret and cowardly device has been used to undermine their foundations and blast their prospects. Meanness has often assumed the garb of decorous formality and hurled its weapons upon the unsuspecting object of its jealousy and spite. But there is a censor in life which follows every act of meanness that is committed, and sooner or later pays it a well merited retribution. Right must win. We are prepared to face our duty manfully and bravely, and to use the talents God has given us for the well being of our fellowmen. In such an aim and with such a goal in view, we commend ourselves to the good judgment of our readers and of all right thinking men, hoping for no better epitaph than that 'we tried to do our duty.'

In our April 1st, 1892 number we produced this article—

"After a long silence and seeming inactivity, we have approached this subject once again and have acted upon the suggestion of the Government of India to direct our inquiries to the Provincial Governments of the country, to each of whom we have sent a copy of the annexed letter, which explains our latest position.

CALCUTTA, 11th March 1892

TO THE CHIEF SECRETARY

TO THE GOVERNMENT OF BENGAL

DEAR SIR,—In connection with this office letter, dated London, 29th April 1891, and the Government of India reply thereto, dated 17th June 1891, referring to the support given by Government to Indian medical journals, I was informed by the Government of India that 'the purchase of, or subscriptions for books, is now borne by Provincial Revenues.'

As this Journal has been carried on successfully for the past two years without Government aid (its subscription lists being open to inspection to verify this assertion), sufficiently demonstrating its hold upon the confidence of the profession in India,—both official and non-official—it is my intention to appeal to the various Provincial Governments with the object of securing for independent journalistic enterprise that impartiality of conduct which is the declared policy of the Indian Government in all its provinces, and the effective and honest working of which is the best stimulus to private enterprise.

I would beg to point out that the *Indian Medical Gazette* is the only other medical journal in the country, that it receives very liberal support from the State, and I would respectfully urge that as we both occupy the same field, any official aid given to one, must be detrimental to the other. I am fully prepared to do without State support, and to allow the question of the continued existence of this journal to rest with the verdict represented by the support and confidence of the medical profession, but I feel bound to claim and to solicit that State support be henceforward either withheld from the *Indian Medical Gazette* or that such support be equally divided between us.

I would further urge that there can be no special merit attaching to the *Indian Medical Gazette* to bind the Government to support it. The fact that State aid was a necessity to inaugurate and establish medical journalism in this country twenty-five years ago, cannot possibly be put forward to-day, and our several subscription lists will effectively settle the question of our work of usefulness to the profession in India, and thus decide the feasibility of survival without State aid. All I ask for is "fair play," and this I beg to claim as the first consideration of any Government towards its subjects.

In view to further action in this matter, may I beg to be informed as to the number of copies of the *Indian Medical Gazette* subscribed to monthly by your Government, and the money value thereof.

Yours faithfully, JAMES R. WALLACE, M.D.

Editor and Proprietor, *Indian Medical Record*.

"We are hopeful that the Government will see its way to the withdrawal of the subsidy it pays to the *Indian Medical Gazette*, and thus permit both journals to enter the field of their common enterprise on a fair and equal commercial basis. There is a very distinct precedent for the line of action we are adopting. Some years ago two rival engineering journals came into existence, and it was found out by one of them that the Government had subsidised the other. An appeal was made to the Provincial Government concerned, and as no satisfaction was received, the matter was forwarded on to the Governor-General. Here, too, little satisfaction was obtained, and appeal was made to the Secretary of State for India, who ordered the subsidy to be stopped."

The various Local Governments thus approached sent replies to the above letter which we here epitomise—

Bengal Government—"The Lieutenant Governor sees no reason to modify the arrangement under which certain officers are supplied with copies of the *Indian Medical Gazette*."

Burma Government—"No copies of the *Indian Medical Gazette* are subscribed for by this administration."

Punjab Government—"This Government subscribes for five copies of the *Indian Medical Gazette* at an annual cost of Rs 75."

Madrass Government—"Government is not prepared to supply the information asked for."

Bombay Government—"This Government does not subscribe for copies of the *Indian Medical Gazette* in the Civil Department." "Twenty four copies are subscribed for by this Government in the MILITARY Department, and supplied to Station Hospitals in this Presidency at an annual cost of Rs 860."

Central Provinces—"The Chief Commissioner finds it desirable to procure one Indian medical journal for Civil Surgeons' libraries, but that a second journal is unnecessary. Accordingly, one copy of the *Indian Medical Gazette* is bought by the administration for each of the 18 Civil Surgeons in this Province."

N. W. P. and Oudh—"On the recommendation of the Inspector-General of Civil Hospitals of these Provinces, a similar number of copies of the *Indian Medical Record* will be subscribed for by this Government as for the *Indian Medical Gazette*."

It will thus be seen that we moved in a perfectly reasonable and constitutional manner to get access to the journals under the custody of State patronage, with the result that while the Governments of Bombay, the Punjab, the Central Provinces, Burma and the N. W. P. and their counterparts acknowledged our right to obtain the information we sought at their hands and provided it, the Bengal Government, which offends most in its godfatherly care of the *Gazette*, positively evades declaring its questionable appropriation of public money for the up-keep of its pet journal, and the DEVIL DAMONIA GOVERNMENT OF MADRAS, reigning like Babylonish, with a secret seal upon the deeds of its Council Chamber. And this is allowed to pass as a grim parody for constitutional Government! "Woe unto thee Madras!" It shall be more tolerable, &c., &c." We shall not complete the quotation, lest like as in the language of our tirade upon the Indian Government for selling it "a wastefully gilded lacubus," the opinion of the Advocate-General shall again be taken as to whether a case for our prosecution could stand. The negative opinion was given then, but who knows what may not come of predicting the still severer judgments of the great ancient cities of the plain—Sodom and Gomorrah—upon benighted Madras! We should probably be hanged and quartered, and so we prudently desist.

It might be pleaded that the Government has a perfect right to distribute a certain number of copies of the *Indian Medical Gazette* among its subordinate officials by way of further educating them; or that it has an equal right to endow the libraries of Civil Surgeons by the free distribution of medical literature.

We would meet these suppositions by absolute facts. The *Indian Medical Gazette* is a MONTHLY journal, and charges a yearly subscription of Rs. 18. It is therefore beyond the means of Government medical subordinates, such as Hospital Assistants, for whom the Government aid is presumably given. The *Indian Medical Record* is a fortnightly journal, and charges a yearly subscription of Rs. 6 to Hospital Assistants. That it meets the needs of these classes is proved by the very large numbers who subscribe to the *Indian Medical Record* in spite of the gratuitous distribution of the *Indian Medical Gazette*. To defend the "grant in aid" of the Government to the *Indian Medical Gazette* on the plea of embellishing the libraries of Civil Surgeons, is altogether unjustifiable; for while there may be some justice in the plea of free distribution among its poorest class of medical servants, there surely can be no justice in offering "free education" to those who can easily afford to pay for so comparatively costly a journal as the *Indian Medical Gazette*.

The fact is the BENGAL GOVERNMENT is nearly the sole supporter of the *Indian Medical Gazette*, and we are informed that it pays its proprietors the handsome YEARLY SUBSIDY OF SEVEN THOUSAND TWO HUNDRED RUPEES!

We claim that the verdict of the local medical profession is in favor of the *Indian Medical Record*, and this verdict is alone obtainable by a comparison of the subscription lists of the two journals.

We have reasonable grounds for doubting that the *Gazette* can even claim to be called a *Service* journal, if the

support of its proprietors from the Indian Government and its Officers is to be used as a criterion.

We would add that the Bengal Government has been in demand of the *Indian Medical Gazette* and of the *Indian Medical Record* to place substantiated copies of their respective subscription lists in its hands, to be compared, which of the two journals has the confidence and support of the local medical profession whom the State is professedly so solicitous and anxious to uplift and educate, as to spend yearly over 7,000 Rs. of tax-payers' money in trying to accomplish its object.

We again affirm that we are perfectly able to exist—and our viability is proved by an experience of nine years of life, and our development into a fortnightly journal and our projected development into a WEEKLY from the 1st January 1899, are tangible proofs that we can do so—without the support of Government, and we now declare that we do not ask for any portion of the "grant in aid" given to the *Indian Medical Gazette*, and since we have placed within the reach of the local profession, a cheap and thoroughly approved fortnightly medical journal, serving all and more than the purposes of the *Indian Medical Gazette*, we have made good our claim to ask the Bengal and other Provincial and Presidential Governments to cease applying public money for the support of another medical journal, carried on as ours is by a private proprietary.

We claim with some degree of pride, that the *Record* has done more for the building up of the local medical profession in the nine years of its existence, than the *Indian Medical Gazette* has done in the quarter of century that it has lived. It has not sought to do this and it cannot possibly do so. Its policy could not harmonize with any scheme that would place the local profession on a plane of equality with officialism. We claim too, that the *Record* has greatly encouraged and advanced literary effort on the part of all grades of the local profession, such as the *Gazette* has never done.

We have sunk a large capital in our enterprise and we are about to still further improve and enlarge the *Indian Medical Record* to make it still more worthy of the confidence and support of the local medical profession, but we believe we will have the approval of all right thinking men the world over, in asking the Government once for all to desist from inflicting a serious wrong upon independent medical journalism in this country by subsidizing and protecting one journal in preference over others, and thus adopt a line of conduct that will be consistent with the position of an impartial and liberal Government, giving one and all a FAIR FIELD AND NO FAVOR.

The Indian Government once subsidised *The Indian Engineer*, and its rival *Indian Engineering* appealed against the injustice. The appeal failed to move the Indian authorities, but when the grievance was laid before the SECRETARY OF STATE FOR INDIA, the edict went forth that the subsidy should cease, and it ceased.

This is an encouraging precedent for the local profession and for this journal. We shall loyally lay our case before His Excellency the Viceroy in Council, and failing in our appeal, we will proceed to the Secretary of State for India, and we shall not cease in our efforts till we have secured redress for a grievance that affects the interest not only of the local profession but of the general public in India.

THEORY OF THE NEW CHARACTER OF DISEASE, BAKES AND OTHER NEWTON'S DISEASES. SUGGESTION APPLICATION TO TREATMENT.

The study of medicine at the close of this 19th century can certainly not be accused of being dull, whatever its daily routine of practice may be; it opens up fields for speculation and during flights of imagination sufficiently varied to attract the wildest romancer and we find the fertile pen of Mr G. WELLS doing for it what JULES VERNE did for other branches of science not so long ago.

Mr. WELLS has happily hit the mood of the hour, he "shoots fully as it flies," for it is but a truism to say that where the amount of exact knowledge is small, the mind runs riot and tends to indulge in speculative fancies and gaudy but shadowy hypotheses.

From the earliest times medicine has been enlivened by these delightful mental exercises.

We can watch its progress through past ages hand in hand with superstition, priestcraft, astrology, magic and all the other occult and mysterious influences which from time to time have reared up their heads, and hood-winked mankind, by playing upon his supernatural fears; while the theories that have been propounded have been as numerous and often as evanescent as the leaves that autumn scatters to the winds, or the snow that falls upon some mountain torrent.

Medicine like other things has had its romance, nor is the final page of the last volume yet reached, far from it indeed! the plot is only deepening, never have the imaginative faculties had freer scope or more complicated situations to deal with, and no one can foresee what startling and unexpected denouements may unravel before us.

What could be more strange than the modern serum treatment of disease? Could anything savour more of savage superstition or of the barbarity of the middle ages, yet strange as it is that we should try to cure our diseases by injecting into our bodies the blood-serum and extracts from various organs of lower animals, it is an accomplished fact, it is the teaching of the leading pioneers in medicine, it has been baptised by much research and comes upon us crowned with the halo of science.

It is only necessary to read some of the recent contributions to medical literature, such as Professor FRASER'S address on Medicine at the Annual Meeting of the British Medical Association at Edinburgh, of which we gave an outline in our issue of October 1st, or Dr. HEDDARUS' articles on "The Present Position of the Therapy of Traumatic Tetanus" translated by us from the *Munchener Medizinische Wochenschrift*, to see that there are many among the supporters of this form of treatment who think that at last the bars have been removed, and that they have had a glance through the gates which guard some of Nature's most intricate secrets.

Whether or not our teachers have been led astray by blind enthusiasm time will tell, but in view of past failures and disappointments it is well to preserve an open mind and to greet each new discovery with caution and reserve.

In our issue of 16th August we drew attention to the observations of M. ARLOING which expose certain flaws in the logical sequence of deductions which have led up to the present position of serum treatment. M. ARLOING has

observed the agglutination of the agglutinative serum reaction; he has shown that this reaction can be obtained after the treatment of animals by certain chemical substances, as well as by the introduction into their bodies of specific bacilli.

The observations are of the greatest interest and it still remains for the advocates of serum treatment to explain them away; for what they seem to amount to is, that we can place our bodies in the same position of defence against certain diseases by the inhibition of certain well known drugs such as eucalyptol, guaiacol, creosote etc, as by the newest serum treatment, in as far, at least, as the agglutinative reaction is a measure of defence.

We now come to discuss the practical import of the communication made by Mr. BAKES of Bacharest to the French Academy of Science, a full translation of which will be found in our 16th September number.

M. BAKES was led, by a series of observations, which we need not recapitulate, to try the effect of injections of nerve substances derived from the spinal cords and brains of sheep and rabbits in certain diseases as Malaria, Neurasthenia, Epilepsy etc. M. CONSTANTIN PAUL, communicated the results to the Academy of Medicine at Paris in February 1899 and stated that he was convinced of the good effects brought about.

Later on M. BAKES extended the method to the treatment of Rabies, he says, "I have tried to prevent or cure rabies by my method, that is, by the subcutaneous injection of a certain quantity of the nerve substance of the bulb and spinal marrow of healthy animals."

As the result of his preliminary investigations in this direction he states, "We are continuing these interesting experiments under altered conditions of infection. But we are anxious to publish these preliminary results which prove, that it is possible to antagonise rabies by injections of nerve substance derived from the bulbs of sheep which are healthy, and have undergone no previous treatment."

As M. BAKES is well known to be one of the most accurate observers in Europe his results must be received with all respect. And it is obvious that if his anticipations are realised the Pasteur method of treating hydrophobia will be a thing of the past.

M. BAKES' experiments are sufficient to show that normal nerve tissue contains some substance which is inimical to, and neutralises the poison of rabies; this being so, it is only a matter of time to isolate it, and to concentrate it sufficiently for practical therapeutic purposes.

They show that it is not necessary to employ nerve tissue taken from animals which have previously suffered from rabies, experimentally induced.

The basis of Pasteur's treatment is, that the presence of the protective substances in the spinal cords of the rabbits employed, is due to, and the direct result of, these rabbits having suffered from rabies (induced by inoculations); that, in other words, the specific action of the poison of rabies was to produce in the animal an antidote, an antitoxin.

BAKES' experiments show the fallacy of this hypothesis and of all deductions drawn from it, and his simple method of treatment will be free from the many obvious objections which have been, and can be advanced against Pasteur's.

Striking and revolutionary as all this is, it does not exhaust the interest and importance of the new treatment which M. BARRÉ speaks of as "his method." We find that it is also applicable to Tetanus and other poisons.

He says "By the results obtained by WASSERMANN and TAKAKI in tetanus as well as those obtained by VIDAL, MATHIASZ, etc., in strychnine poisoning my procedure of treating certain maladies of the nervous system by the injection of the normal substance of the brain of sheep has acquired a solid experimental basis."

At the time of writing we can go even further than that, for a remarkable and early fruition has attended the researches of M. BARRÉ.

With respect to Tetanus its practical application has been tested and proved successful, by Dr. KROKIEWICZ of Warsaw.

Last July Dr. KROKIEWICZ had two cases of tetanus under his care, one of these he treated by the antitoxin method the other according to the method of M. BARRÉ by the injection of the fresh emulsion of the brain of a calf.

The two cases differed but little in severity, that treated by the antitoxin method (a man) had a shorter incubation period and was consequently more acute, while in that treated by M. BARRÉ's method (a woman) trismus was more marked, the difficulty of feeding was great, and the general condition not so satisfactory.

The course under treatment was very different in the two patients. In the woman, two injections of brain emulsion representing in all about $\frac{1}{2}$ oz. of brain substance, effected a complete cure in eleven days, with no ill-effect other than the formation of two small abscesses at the seat of the second injection which was somewhat too concentrated. The man, on the other hand, received four doses of antitoxin (1 in 10,000) amounting in all to 196 c.c.m., and yet was not cured for eighteen days. Furthermore the brain emulsion produced an almost immediate alleviation of the tetanic symptoms so that the patient begged to have the injection repeated, the administration of the antitoxin, on the other hand, was followed by severe paroxysms, sleeplessness, fever, and a sense of dread which allowed it to be repeated only under the pressure of dire necessity.

This it must be admitted, is a very remarkable result, it is all the more remarkable considering that tetanus is one of the diseases in which such splendid results have been confidently expected from the antitoxin treatment, and considering the immense boom there has been in antitetanic serums, of which we believe there are no less than seven in the market.

This new method of treatment is sure to attract a large amount of attention and its merits will be carefully tested; should it prove as effective in other hands as it has done in those of Dr. KROKIEWICZ it will be another and severe blow at the whole theory on which the treatment of disease by antitoxins is based and will considerably modify the practical aspect of many questions which modern bacteriology has somewhat too confidently accepted as definitely settled.

It is to be further noticed that M. BARRÉ does not limit the application of his method of treatment to the diseases already mentioned, he says,

"Further our experiments have proved that the substances contained in the bulk, and which antagonise the infection of rabies and of tetanus, act upon certain toxins, certain alkaloïds, certain poisons differing in character in such a manner that there can be no doubt that my procedure may have a beneficial action in different nervous diseases of a toxic or infectious nature, as well as in those diseases in which favourable results were obtained by CONSTANTIN PAUL and myself."

—o—

REST IN THE TREATMENT OF SKIN DISEASES.

DR. W. ALLEN JAMIESON, M.D., F.R.C.P., F.Lin., in his Presidential address in the Section of Dermatology of the British Medical Association meeting recently held in Edinburgh, thus defines Rest.

Rest consists in the removal of irritants, whether these be such as worry and distress the mind, or tease and vex the body.

Why is rest necessary? Rest is required as a consequence of fatigue or exhaustion. It is our duty to rest the skin from the deeper side by what therapeutic means are at our command. Thus all internal causes which may be amenable to be eliminated, by correction of dietary, by cutaneous sedatives, of which antimony may be taken as a type, by hæmatics, and by agents which influence metabolism, such as arsenic, or flush the sudoriferous canals as pilocarpin.

More closely considered rest is procured for the skin by freeing it from the effects of the over activity of its own constituents or appendages, of this an example is provided by ichthyosis. The most prominent feature here is the continual accumulation of the horny layer on the surface, in place of its regular and imperceptible desquamation.

Here by certain keratolytic applications of which resorcin is the chief, used as a soap supplemented by its employment as an ointment or in combination with glycerine of starch, we can in many cases perfectly remove the abnormality. We can compel the over-active epidermis to rest by these means.

We find evidence of increase of the secretory energy of both the sebaceous and sweat glands, and in this way also is the quietude of the skin disturbed, whatever theory of seborrhœa be accepted, it is certain that either in the concrete or oily form it acts as an irritant. Our efforts to obtain rest in this instance must go further than merely removing the accumulation of oil and degenerated epidermic scales.

The anaemia must be corrected by toning up the soil, not merely by iron to enrich the blood, by mercury to neutralise the syphilitic virus if present, but by ergot or ichthyol to constrict the vessels of the peri-glandular plexuses. Locally sulphur which has a peculiar and specific desiccating effect, quite apart from any presumed anti-parasitic one, and the astringent action of cold water are our most reliable remedies.

Hyperhydrosis weakens the tissues by converting the integument into a swamp, here we employ small quantities of salicylic acid, 3 per cent. in a bland pulverulent medium as powdered tale.

Another state in which our efforts must be directed to procure rest for the skin is that in which it is necessary to modify abnormal perversions of functional activity. This

A certain amount of food must be taken, and the patient must be kept in a comfortable position. We may meet on occasion these forms which are especially dangerous at the end of life. The sign of the patient is a general swelling on the neck which must be treated for its repression. One of the most troublesome of the eruptions that affects infants and young children, especially of the poorer classes, is *Urticaria* or *nettle-rash*. The skin in those affected, almost always exhibits evidence of malnutrition. Thus it is usually dry, thin, and anemic. All faults in feeding and hygiene surrounding must be removed and instead of the strong carbolic soap often employed, we prescribe either merely ablutions with gruel or with a superfatted naphthol soap; cotton or flannel to be worn next the skin; accompanied by the inunction of glycerine of starch made with double the quantity of glycerine of that in the Pharmacopoeia, medicated by the addition of naphthol and camphor, tamenol or resorcin. Sometimes an oil containing menthol and a little lanoline or adeps lanea proves more grateful. Internally antipyrin in small doses at night, is valuable in promoting sleep.

In old age also the skin is apt to be thin and anemic, the result of atrophy, here the sudorific action of pilocarpin can be brought into play to calm the pruritus, if this be repeated night after night for a couple of weeks, a great amelioration will certainly, sometimes a permanent cure be obtained. Glycerine of starch and superfatted naphthol soap will also be useful in addition, with warm under clothing of the softest wool.

Of the inflammatory affections which necessarily call for rest we naturally turn to eczema as an example; its relation to catarrhal processes cannot be overlooked. It does not matter whether we regard it as a parasitic catarrh or not, provided we bear in mind that it is a catarrh. As in bronchitis we endeavour to soothe by keeping the air of the apartment moist and warm. So in eczema we envelop the raw denuded itching surface with a soft, bland, aseptic medium, a starch jelly with which is combined a proportion of boric acid.

In general dusting with a weak, salicylic acid powder, or painting with nitrate of silver dissolved in sweet spirits of nitre before renewing the above poultice, is sufficient to destroy micro-organisms where the boric acid fails.

In order to overcome the infiltration or induration of the skin which accompanies eczema and which persists as a leathery condition after the surface has healed, it is recommended to envelop the surface closely in strips of the salicylic soap plasters which PICK of Prague has introduced. The plaster is worn for several days up to a week. There should be no resin in it.

In some cases which may present the seborrhoeic type, which may implicate the cheeks and seem to have had their origin in seborrhoea of the scalp, or eczema of the margins of the eyelids, the above treatment fails, and UNNA's plan of olive muslin is recommended; a porous cloth carrying on and in its substance a thick stratum of an ointment of such hardness and consistence that it just melts slightly at the heat of the body.

When pieces of say this zinc ichthyl olive muslin are applied to the skin of the face, we obtain an amount of rest attainable by no other means with which I am acquainted.

When eczema is already extensive, where large areas of the trunk or the lower limbs are involved, or threaten to become so, confinement to bed is imperative.

It sometimes happens that a case of eczema confined to bed and carefully treated, ceases to improve after a certain time. When this is the case a cure not infrequently follows an entire change, the patient is sent home and allowed to follow his ordinary pursuits.

In acute the question of how best to procure repose for the skin is more complex; the worst examples of acute eczema to be encountered in these subjects, whose skins are coarse, thick, muddy, and pale. Treatment in acute has several sides. On one hand we must endeavour to thin down the abnormally thick epidermis.

This is effected by various methods in accordance with the degree and the resistancy of the integument.

Sometimes ointments which contain salicylic acid, soap and sulphur, as in the admirable one of BONNÉ, or it may be necessary to have recourse to the resorcin desquamating paste suggested by UNNA or to the application of his resorcin or salicylate plaster muslin.

At the same time the sulphur nullifies the pus-determining properties of the micro-organisms.

THE ROLE OF PARASITES.

The inquiry as to how to secure rest when parasitic agencies are to blame has been left to the last. At the present moment the trend of investigation is to try and find an organism which can be credited with the causation of every cutaneous disease, the effort is a laudable one, for in due time (it will demonstrate which ailments are and which are not parasitic in origin. A man of 31 consulted me for a too copious fall of hair which he feared would occasion baldness. His hair was dark and plentiful, but there was a considerable amount of seborrhoea in the form of branny greasy scales, distributed pretty uniformly over the scalp. By the use of a salicylic and sulphur pomade the seborrhoea had entirely disappeared in the course of a month, but the hair still fell out too abundantly.

If SABORAND is correct that the bacillus he has discovered is the cause of seborrhoea and of seborrhoeic alopecia, how can we explain the complete cure of the seborrhoea in this case, the healthy state of the scalp, and yet the persistence of the loss of hair!

There is an entire consensus of opinion that erysipelas regarded as a medical disease is caused by the streptococcus of FERHISEN giving rise to spreading inflammation of the skin, or mucous membrane, having contagious characters.

Though constitutional symptoms manifest themselves almost consecutively with the onset of the disease, it is for a time a surface ailment. And there is one remedy at least which can in the large majority of cases strangle it, so to speak, at its birth, if used promptly and efficiently. This is ichthyl. It should be thickly smeared over the inflamed area as a 25% ointment made up with prepared chalk and vaseline and covered with a layer of cotton wool.

The treatment of pityriasis versicolor is well enough established but the prevention of recurrence is scarcely

with a simple method. I have been in the habit of directing my patients to continue (after cure) to wash for a week or two with a resorcin and antiseptic acid soap. In this way a permanent cure has resulted.

TYPHOID FEVER IN BELFAST.

TEMPORA mutantur, and fashionable theories also? At last we have a widespread and destructive epidemic of typhoid fever in which the old scapegoat, the water supply, is not at once set down as the medium of infection and communication?

It will be remembered that last autumn Belfast suffered from an epidemic of typhoid, the present one is however more serious as the following figures from the *British Medical Journal* show:—

WEEK ENDING	1897.
June 28th 1898 ... 34 cases notified ... 28 cases	
July 2nd " ... 66 " ... 56 "	
" 9th " ... 57 " ... 44 "	
" 16th " ... 69 " ... 43 "	
" 23rd " ... 81 " ... 37 "	
" 30th " ... 98 " ... 59 "	
August 6th " ... 195 " ... 45 "	
" 13th " ... 143 " ... 61 "	

If ever a city reaped the harvest of its neglect of all sanitary rules, the city of Belfast is assuredly doing so now. Anything more disgraceful than the revelations made before a committee which sat some five years ago to inquire into Belfast sanitation, it would be impossible to imagine.

Houses of the worst possible description, entirely devoid of all sanitary appliances or means of cleansing, were being run up at an almost unprecedented rate. But the worst feature of all to our minds was the nature of the sites on which these houses were built. There is plenty of low lying slob land about Belfast, totally undrained, where in wet weather the subsoil water lies level with the ground, and the falling rain turns the inequalities of the surface into a series of unhealthy puddles.

It is on soil of this description that a large portion of the dwellings of the labouring classes are erected, and it is on ground of this kind, when there is any open space left, that the children of the poor collect and play about.

A large portion of such dwellings are also erected upon made soils in which, according to the evidence given before the Committee above referred to, decaying organic and even fecal matter could be identified.

It is to the absence of building laws, or to their total neglect, by interested and unscrupulous persons that we would attribute the unhappy notoriety for unhealthiness which Belfast has gained for itself.

On this point the *British Medical Journal* says:—"In the opinion of a large majority of those most competent to judge, the pollution of the subsoil with filth and the imperfect removal of refuse matters, is the chief cause of the undue prevalence of typhoid fever in Belfast. It is a cause always at work and fully adequate for the production of the state of things now existing. Closely associated with this cause, indeed partly identical with it, must be put the erection of cheap houses upon insanitary sites, and

decisions of adequate sanitary arrangements. This has prevailed to a really frightful extent in Belfast, and the city is now reaping the results of the constant neglect of its corporation, health officers, and town surveyors in past years. Many houses of poorer class have no waterclosets and no means of removing filth by any backyard or rear entrance."

According to this Journal there are three possible causes (of the epidemic) which demand the most thorough and careful investigation.

1. The water supply.
2. The new main drainage system, not long ago completed at a cost of £300,000.
3. The pollution of the subsoil with filth, and the imperfect removal of refuse matters.

To these we would add a fourth, *the level of the subsoil water*, for although it may justly be held that a saturated soil without specific contamination cannot give rise to typhoid fever, yet we cannot say to what extent it may favour the production of the specific organism; while without doubt it acts prejudicially upon the health of the community and lowers their vitality.

For these reasons we think it is worthy of being investigated separately and it may be noticed that Mr. ADAMS, the Health Officer of Maidstone found a close connection between rainfall and subsoil water level and the course of the Maidstone epidemic.

Regarding the water supply the *British Medical Journal* says—"But it must be admitted that all efforts to connect previous epidemics of typhoid fever in Belfast with defects in the water supply have failed. It has never been shown that the parts of the town supplied by the Woodburn water suffer more than those supplied by the Stonyford water, or *vice versa*, nor have epidemics in the city ever been proved to be traceable to any temporary pollution of either source of supply."

The same journal further remarks on the new main drainage scheme.

"It is a curious and disquieting fact that since Belfast completed an elaborate and costly system of main drainage typhoid fever has been decidedly more prevalent than it was previously."

This system as we have seen cost £300,000. Large schemes of this kind have an extraordinary attraction for the present day Sanitarian.

Some how or other they do not always hit the mark, which shows that the preliminary investigation was not searching enough, and that our knowledge of sanitation on the large scale is mainly empirical.

On this subject the *Public Health Engineer* further adds:—"Those of our readers who will remember the admirable articles contributed to *The Public Health Engineer*, by Mr. HARRIS REEVES, on the Maidstone Epidemic from a Sewer Gas Point of View, and the articles of Mr. BROWN on Sewer Ventilation, will possibly have no difficulty in accounting for this "curious and disquieting fact." We shall not be surprised to hear that sewer gas has a good deal to do with the mystery."

COMMENTS AND NEWS.

"OFFICIAL PLAGUE" IN CALCUTTA. — WAS IT A FRAUD?

We quote from our excellent weekly contemporary *The Saturday Journal of Calcutta*—

"The plague has left Calcutta, and the unpleasant controversies that have arisen in connection with it may very well be dropped. There is, however, one indirect issue arising out of the wicked charge levied against the Government of manufacturing plague, that I would like to draw attention to. The statement weakened the hands of the authorities in dealing with the natives, large numbers of whom, already violently opposed to the plague regulations, came to believe that the Government was acting merely from a capricious desire to annoy. Now is it, or is it not, the duty of every European in this country, or all who have white blood in their veins, to rally in times of danger to the support of the Government? A weekly medical paper, published in Calcutta, and circulating among Anglo-Indians, has the following headings to the notification declaring Calcutta no longer infected: "No More Official Plague in Calcutta. The Governor's Declaration that the City is Free. Official Plague Manufactory still to be kept open." One of the first claims of the Anglo-Indian and Eurasian community to the consideration of the Government, has been its steadfast loyalty to the Crown. I hope then that the leaders of that community in Calcutta and elsewhere will come forward to publicly disassociate themselves from these persistent efforts to charge the Government with lying and fraud, and to play into the hands of the most seditious and disaffected sections of the native press."

THE CALCUTTA PLAGUE AND ANGLO-INDIAN LOYALTY

THE above comment in the *Saturday Journal* (which is the offspring of the Calcutta *Englishman* by the closest marital relationship), raises two important questions (1) the true diagnosis of Calcutta Plague and the government measures for dealing with the natives and (2) false and true loyalty to the Government.

We have consistently maintained that Calcutta has not had a visitation of *true* plague. We say "true" plague because every standard work on Sanitation Medicine defines plague as "a contagious epidemic disease, and this 'Rasley Plague' (there is no other name for it) has been neither contagious nor epidemic. It is a flagrant contradiction of terms to style the Calcutta Official Plague, 'plague' at all. Official opinion on this matter was that *true* plague was present in Calcutta. Judged by the clinical and epidemiological manifestations of the disease with which Calcutta was afflicted, Mr. RISLEY, one of the Secretaries to the Bengal Government, and a few of his State paid medical advisers, upheld his opinion, that our city was plague infected. Their prophecies regarding its spread have been as false as Balaam's, and the opinion of the medical experts is so utterly disgraced and confounded, that it does not find practical or logical support from either the clinical or the meteorological behaviour of the strange febrile disorder which they terrifyingly hailed as THE PLAGUE. So that from start to finish, this scare, created and fostered by State-officials, has proved itself to be a huge unmitigated medical fraud. It is no disloyalty to speak the truth fearlessly even though such expressions challenge the policy of the Government and lay bare its weakness and rottenness. It is false loyalty, disastrous alike in its duplicity and in its consequences, to betray the Government into a course of action that is positively dangerous both politically and financially, thereby

weakening the Government's position, and wrecking the reputation and prestige of the nation. We maintain that the Englishmen and the Bengal Plague Commission are jointly responsible, under the misguiding influence of official medical men, who simply said what their paymasters bid them, that the whole commercial machinery of the metropolis was dislocated, its trade utterly paralysed, and the domestic peace and happiness of its European and Indian inhabitants wantonly disturbed for almost half a year. We are second to none in our loyalty to the Government. The British Government of India is the greatest of Providential blessings in the destiny of this vast Oriental Empire, but while admitting that this is so, we as frankly and as fearlessly declare that the policy of the Indian Government is not only misapplied and wrong in its effect on the peace and welfare of the domiciled European and Indian communities, but it is from a sense of deep and earnest loyalty, that we warn the Government that its treatment of these communities, more especially the domiciled Anglo-Indian community, has created the intensest feelings of disaffection towards such policy, and it belittles a government, if actuated by a desire to deal righteously and impartially with its subjects to disperse and eradicate the causes of such disaffection, as to do otherwise is to be unrighteous, unjust and impolitic.

HOW "PROFESSORS" ARE MADE IN INDIA.

WHEN "General" O'BRIEN shook the dust of India off his shoes and bid farewell to the old fashioned operation theatre and tools of the Calcutta Medical College Hospital, there was an uncomfortable stir in the dove-cot of the Bengal Secretariat. Old women and young women were busy pulling wires, and from all accounts there seemed to be a pretty hard nut to crack, in finding a successor to the genial and courteous sawbones who had just gone back to the "Green Isle." Not that it was difficult to find a *suitable* and fully qualified successor to O'BRIEN. To be "suitable and qualified" counts for nothing with either the Imperial or Provincial Governments of India. There were a few competent surgeons and anatomists of the Indian Medical Service quite ready and at hand, who had a legitimate claim to the Professorship of Surgery and the First Surgery of the Calcutta Medical College and Hospital, but being bent on providing for "Dowry," a job had to be perpetrated and perpetrated it was. The exigencies of the occasion were peculiar. Dr. BOVILL, a Senior Civil Surgeon of the I. M. S. and a Colonel to boot, was vegetating at Darrjiling. His term of office in the Sanitarium had expired and therefore Dr. BOVILL must be found with a post suitable to his rank and seniority. Howrah was the place but unnamed in Howrah was Dr. R. D. MURRAY. What was to be done with MURRAY? Make him "Professor" of Surgery was the reply and so the conundrum was solved, BOVILL came to Howrah and MURRAY became a "professor." It was all so natural to the legendary proclivities of the Bengal Secretariat. They manufacture professors by a patent process, a thoroughly secret invention, the only material needed being a workable Secretary to a Government and an I. M. S. officer for whom the Secretary longs to do a good turn. The elastic mental calibre of the I. M. S. man with his hydra-headed intellectual and scientific capacities, is a marvel to dwell upon. The whole phenomenon is ludicrous in the extreme. Yet so it is, for we find an I. M. S. man who is only a good general practitioner, who has not the smallest pretension to being called a surgeon, who never dreamed of teaching surgical anatomy nor general and operative surgery, pitchforked into a professorship in surgery and a consulting surgeoncy.

That Dr. MURRAY'S appointment has stirred up the strongest indignation in Calcutta goes without saying, but that the Director-General of the Indian Medical Service, will

"The rate of increase of the income of asylums for their care and of expenditure on this account, is indeed giving every taxpayer of intelligence grave reasons for thought. The most striking anomaly in the whole thing is that the Lord Chamberlain is the head of this vast machinery for the management of the insane. Hence it is that the personnel of the inspection of lunatics and of asylums by bar-

...the first and most important consideration in the establishment of a plague hospital is the selection of a suitable site. The site should be in a quiet, airy, and well-ventilated place, and should be accessible to the public. The hospital should be built of brick or stone, and should have a large, open space in front of it. The site should be in a quiet, airy, and well-ventilated place, and should be accessible to the public.

The establishment of a plague hospital requires a large amount of money. The cost of the building, the purchase of land, and the payment of salaries to the staff will be considerable. It is therefore necessary to secure the necessary funds before the hospital can be established. The Government should be asked to contribute towards the cost of the hospital, and the public should be encouraged to donate towards it.

THE LONDON "NURSING RECORD" ON ANGLO-INDIAN NURSES.

THE above named contemporary :—"The Indian Medical Record" in taking up the cudgels in defence of the Anglo-Indian Nurse, and asserts that injustice is done her by the importation of British Nurses for plague duty. "We are quite of opinion that if Indian trained nurses are to be found in sufficient numbers, well qualified to undertake the work of plague nursing, their claims to appointment deserve every consideration, but as a matter of fact, the lack of efficient nursing, and the condition of the plague hospitals before English nurses bravely went, at the risk of their lives, to give skilled assistance to the plague patients, is notorious."

"The contemporary states that both doctors and nurses could be obtained in India in any number required. We are, therefore, anxious to know, therefore, why they were not required. Mr. JAMES CASTLE, in an article in the *British Medical Journal* in February of last year, stated that "in no disease does one get such immediate results from careful and prompt medical treatment, and as a direct outcome of successful nursing, as in plague," that each two patients required an attendant to themselves if the utmost good was to be done, and that "a liberal supply of doctors and nurses was essential if the lives of the plague-stricken were to be saved." Were nurses in anything like this proportion provided for the plague patients."

"On the face of the published facts as to the condition of the plague hospitals, it is difficult to accept the statement of the *London Anglo-Indian Association*, that "the importation of British medical and nursing labor for plague duty was absolutely unnecessary." If indeed this was the case, then the condition of the plague hospitals was, if possible, even more disgraceful than we reported."

"It is reported by our contemporary that two English nurses sent out to Calcutta for plague duty "with all the bloom of their English complexions, were hastily sent on to Dardanelles, to summer there, as it was feared they might lose their health and their lovely complexions. These nurses are on the "employed list," and are utterly unqualified." This statement, if substantiated, proves, not that nurses are not required, but the necessity of selecting the right kind of woman."

...the first and most important consideration in the establishment of a plague hospital is the selection of a suitable site. The site should be in a quiet, airy, and well-ventilated place, and should be accessible to the public. The hospital should be built of brick or stone, and should have a large, open space in front of it. The site should be in a quiet, airy, and well-ventilated place, and should be accessible to the public.

1. We have learned that a plague is a very spreading disease, which possesses a natural duration, and which is made up of a series of several annual recurring epidemics.

2. That these annually recurring epidemics take place in periods of natural duration, and that the course of each epidemic is completed in or within a year.

3. That each epidemic divides itself into four stages of rise, spread, decline, and inactivity, or quiescence.

4. In a large city in which the disease is fully developed, all known or tried measures of suppression or extinction are useless in each and every stage of the disease.

5. That insanitary and over-crowded houses spread and maintain infection, and cause an increased mortality.

6. That large insanitary districts become permanent plague centres, from which infection is spread in all directions to other districts.

7. That Europeans are almost immune from plague, whether living in the docks, in ships in the stream, or in houses in the native town.

8. That the severity of the mortality from plague falls upon the Hindoo population, as the following table of the Race and Caste mortality as recorded in the last epidemic will show :—

Per 1,000 per annum.			
Europeans	... 1.4	Low-caste Hindoos	... 31.4
Jews	... 15.9	Brahmins	... 34.2
Eurasians	... 31.3	Caste Hindoos	... 34.9
Mahomedans	... 23.6	Lingayets	... 31.4
Native Christians	... 29.1	Bhatias	... 34.0
Parsons	... 24.6	Jains	... 30.2

All that has been said in this letter about plague and plague experience refers to Bombay.

The conclusions to be arrived at from our previous experience, and from our present corrected knowledge of plague are, that when plague is established in a large Indian city it comes to stay, and cannot be extinguished by any means at present known to us. It follows, therefore, that so-called preventive measures are chimerical. In such a city as Bombay the mortality of each plague epidemic can be forecasted with greater accuracy than the progress of a cholera epidemic. What can then be done to prevent the spread of suppression or extinction? Deceive the public by deceivingly deceiving them!

PLAGUE IN BOMBAY.

...the first and most important consideration in the establishment of a plague hospital is the selection of a suitable site. The site should be in a quiet, airy, and well-ventilated place, and should be accessible to the public. The hospital should be built of brick or stone, and should have a large, open space in front of it. The site should be in a quiet, airy, and well-ventilated place, and should be accessible to the public.

...the number of deaths from plague, by ... the total reported deaths and ... the first 12 weeks of the present ...

The second column is evidently to afford a test as to whether the reported mortality returned under pulmonary plague is really due to radiogroup plague.

Week Ending	Recorded plague mortality.	Increased weekly mortality from plague and lung disease in excess of the average added to recorded plague mortality.	Normal mortality of previous five years deduced from total mortality to arrive at a nearly correct plague mortality.

PNEUMONIAL MORTALITY. REAL, SUPPOSED AND IDEAL.

THE *British Medical Journal* publishes a letter from Mrs GARRETT ANDERSON which revives an old question and the ability with which she restates what seems to her the true state of the case will be recognised.

Mrs. T. A. COGHLIN read before the Royal Statistical Society on 21st June last, an able paper on deaths in childhood, showing a mortality of about 1 in 142. The late Dr. M. C. O'NEILL of Dublin, writing in 1869 estimated the rate to be about 1 in 120. Mathews Duncan in 1871 stated the following: "Not fewer than 1 in every 120 women die within the full time of the four weeks of ..."

... thinks that this is incorrect. She has ... from various outdoor and indoor maternal ... a death-rate, when all deductions are made, ... She thinks that the risk to a lying-in woman ... the average ... but upon ... of those who surround her."

... quotes in support ... and ... a case in ...

... have been ...

(1) The fact, that which has generally ... the ... where ... are made to ... by those who ... without reservations or corrections. (2) The ... which is what ought to be attained always, but which is not.

A GRAVE SCANDAL.

We take the following from the *Medical Times* ... The death of a woman from ... with the intention of procuring abortion, reported ... led to remarks on the prevalence of such ... and the dangers thereof. If the law, as it stands at present, is not sufficient to prevent the advertising and sale of ... for removing "obstructions," it is matter of urgency to alter it. Why is it that such a difference is made between cases where death ensues after abortion brought on by ... methods, and those where abortion results from the administration of drugs? Drugs of the most potent kind are advertised, and need to bring on abortion, and there can be no doubt that deaths frequently result. Surely the ... of these drugs are as much guilty of manslaughter in such cases as are the doctors who bring on abortion by the use of instruments. We are heartily glad to have medical abortionists removed from our ranks; but it is a gross scandal that what is punished as a grave crime in a doctor, is allowed in a slightly different form to be perpetrated by unqualified persons. We have shown long ago that persons styling themselves "Madam Fraise" sell medicines capable of producing abortion and consequent death. Must we wait for deaths to be discovered before stopping this trade? And when death results, is to be merely regarded as a "warning to the public?"

PLAGUE CARRIERS.

Reis and Rayet says — "Simla is not at all healthy at the present moment. The Simla Correspondent of the *Times* writes on the 31st October:

"There have been several cases of illness at the station, the patients suffering from an exhausting kind of malarious fever which leaves them very weak. The Commander-in-Chief is among those who are in the doctor's hands and His Excellency is still confined to his room, though the fever seems to have abated. No special guard can be assigned for the prevalence of malaria, but the changes of temperature now in the 24 hours are so great, the sun being still powerful in the day while cold winds from the snows set in at night. Autumn has set in, our last thunderstorm a few days ago being the last we have seen of the rains."

"We feared Mr. Risner would take the ... Simla. His departure from Calcutta has been ... by the death of plague in the city. It seems the ... malaric of the Lower Province is traveling the capital up in the hills. We may now hope for drastic measures to kill malaria, which ... these plague."

[illegible]

THE NEW PHOTOGRAPHY.

WROTE TO THE DE. COLLEGE TRIAL.

[illegible]

It has been definitely settled that delegates from all the Anglo-Indian Associations will meet in conference at Allahabad on the 27th to the 30th December next. Great political issues hang upon the results of this gathering of the kind. If our representatives are true hearted, fearless patriots, an opportunity is close at hand to make a very strong impression upon the Indian Government that the Domiolded European Community will no longer brook the injustice that is being heaped upon its members in every branch of the State service of the country. Our cry must be the absolute **EQUALITY** of the Domiolded British and European Community with the imported Britisher. Let this be mixed with no uncertain sound and every grievance; no matter how great or how small, will disappear the very instant the Government of India issues the edict that there shall henceforth be an equality of rights and privileges in India both for the imported Britisher and his kith and kin in this land. This **MUST** be granted, and the time is coming when the Government dare not refuse it.

RELAPSING fever is again epidemically prevalent in Bombay and is assuming almost epidemic proportions. We read that the deaths have reached 75 a week, that the type is more virulent and that it is most severe amongst the Ghatti population, which also curiously enough provides the largest number of plague deaths.

It is a curious phenomenon that Relapsing fever should thrive at the same time, and amongst the same class of the population as plague, especially when we consider that the arrival of plague as a rule is the signal for most of the other infectious diseases to depart.

The following are some of the most important returns from out stations for the week ending 7th October.

A FLAGON TO BENGAL FLAGON MANUFACTURERS

THE following is one of the sections of the law creating the Florida State Board of Health: "Any person or persons, who shall falsely or maliciously disseminate or spread rumors concerning the existence of any infectious or contagious disease, shall be guilty of a misdemeanor, and upon conviction thereof shall be punished by a fine of not less than \$100 or more than \$1000, or by imprisonment in the county jail of not less than three or more than six months."

What started the Calcutta plague scare? Six months hard labor

1990

the rank of representative of brigade, has introduced a bill into the United States Congress providing for the appointment of a brigade dentist for each brigade with the rank of major, and one for each regiment with the title of captain.

After he has completed his investigation at Quetta, Major A. S. Davies, R. A. M. C. will proceed to Poona for the purpose of making a sanitary investigation into the outbreak of epidemic fever amongst the troops quartered in the Wanowrie

The revival of the plague in the Punjab does not seem to have been very marked. There have been no more cases beyond the first at Karim and one at a village in the Gurmukhar tahsil of the Hoshiarpur District.

It has been decided that the families of any native soldiers who may die while engaged in plague duty shall be eligible for family pensions as if the soldiers had died on foreign service.

Mr. Ernest Hart's services to the British Medical Association are to be commemorated by a scholarship for the "study of Preventive Medicine." This endowment which is tenable for two years is worth £200 (or Rs. \$200) per annum.

A telegram has been received from Durbhanga announcing the serious indisposition of the Maharaja of Durbhanga. Dr. Russell is in attendance, and according to the latest report the Maharaja is making satisfactory progress towards recovery.

A pension of \$5000 has been awarded by the Russian branch of the Red Cross Society to Mr. Henry Durant, the initiator of the society, who is now in straitened circumstances.

In England the professional classes are distinctly taller than those of the lower orders. It is a fact that the Fellows of the Royal Society average taller than any other class of men.

Colonel Deane, I. M. S., Residency Surgeon, Kashmir, will probably succeed Colonel Hutchinson as Administrative Medical Officer of the Central Provinces.

Dr. Marshall, Health Officer of Bangalore, has resigned, asking to be relieved at once, as too many masters had made his position unendurable.

Dr. Lingard, Imperial Bacteriologist, whose health has broken down, proceeds home on a year's furlough at once. A medical officer will be appointed to carry on his duties.

Dr. H. W. Chambers is freed from his duties as District Medical Officer under the Plague Regulations. He is now engaged in writing a book on Indian Fevers.

...the ... of ... has been ... Why

...to the security of the...
...of the Navy was also...
...of the Navy was also...

"Having signed the document to the J. P. McDougal
 Trust was made by the person named in the Trust
 deed?"

Captain Burdett, U.S.A., goes at once to Saigon to act as Agency Surgeon in place of Captain Brown, who met with a severe accident while riding.

Dr. J. Waller Leather has been appointed Assistant Agricultural Chemist and Lecturer in the Government of India at the Forest School at Dehra.

The Principal Medical Officer, Her Majesty's Forces in India, has been asked for the services of sixteen medical officers for employment on plague duty.

Surgeon-Major-General G. B. Roberts, M. A. is working during the cold weather from Calcutta.

Colonel Stephen, Inspector-General of Civil Hospitals, Punjab, avails himself of furlough from the 12th December.

Major M. O'Dower, I.M.S. has been permitted to retire from the end of November next.

Colonel B. Franklin, I.M.S., and Captain Pallen, Wiltshire Regiment, will accompany Lord Elgin home.

WANTED—Medical Gentleman, graduated in Paris, of literary attainments and having a fair knowledge of several European languages, desires a situation with a British Native States, or Tea Gardens. Would serve as Private Secretary as well as Medical Adviser. Address "N. X." care of Manager.

WANTED—A Passed Junior Chemist to take charge of a small dispensary and aerated water factory in the mofussil. Apply with copies of testimonials stating age and salary expected to the Proprietors, The Firehose Store and Pharmacy, Madras, T. S. R.

Medical Practitioners throughout the Indian Empire, and members of the Local Medical Services are kindly requested to send Original Articles and Clinical Reports of cases for publication in the Indian Medical Record. This must be done if the local medical profession is to remove the reproach being cast upon it of apathy and neglect of its duty in literary matters.

Members of the Indian Medical Association whose subscriptions are in arrears are requested to forward their dues to the Treasurer without delay.

Please send all communications to the Indian Medical Record whether to the Editor, Proprietor or Manager, to 50, Park Street, Calcutta.

Subscribe to the the New Weekly Record.
Kindly sign the printed postcard in this
number and return without delay.

ON WOUNDS OF THE INTESTINE CAUSED BY BLUNT FORCE.

Our experience with what is termed in the literature of the subject as to the most frequent cause of such wounds of the intestines are for many frequently due to a localized force acting upon a circumscribed spot, then to a force that is diffused over the abdomen. Of our seven cases, six were thus caused, in one only, Case II did a diffused force (crushing between two vagabonds) cause a complete rupture of the jejunum from the ileum.

In his comprehensive work, giving 222 cases, Petry found that kicks from animals were the most frequent cause (58 cases); falls from men were a frequent cause (31) and that being run over by cars (32 : 238) was also a common cause of rupture of the intestine.

The wounds may be brought about either by a quick moving object striking against the abdomen as the axle of a cart, a falling log, a stone etc., or by a man when running or falling coming in contact with a fixed object such as a post, beam, table corner, axle of a cart etc.

According to statistics far more men than women meet with these injuries. Petry in 222 cases found 217 men and only 15 women. Our cases were all men.

Different ages also suffer to a different extent. Our cases were all between 26 and 45 years. Petry found the great majority between 20 and 50 years of age. Both facts are easily understood. Men are more frequently exposed to the dangers which lead to such injuries and they are especially exposed during those years when their working capabilities are most active.

The manner in which the intestinal wound is caused is sometimes clear enough from the condition of the perforation, its surroundings and position, as well as from a consideration of the force that caused it.

In our cases we could not always definitely say whether the perforation was caused through the *bruising* of the intestine, or through *bursting* of the intestinal wall. Doubtless when the force is great and rapid, and acts upon a circumscribed spot, the intestine can be crushed so forcibly against the spinal column, that the intestinal wall is directly crushed through (vide case IV).

In such cases the edges of the perforation are much bruised, sometimes it happens that there are two holes in the intestine opposite each other but in the same transverse section.

Sometimes the internal pressure of the intestine may be so much increased by a sudden blow that the intestinal wall gives way or bursts, this is especially likely to happen when the canal is full of fluid, faeces, or gas, the probable explanation is that the contents cannot move out of the way upwards or downwards with sufficient rapidity. Obstruction may be caused by kinking of the gut from the blow causing a sudden indentation of the abdominal wall.

When the force acts more in a tangential direction a tear of the intestines may result, this may cause a complete division of the gut, complicated not infrequently with a tear of the mesentery, this occurs especially in the fixed portions of the intestines (Case II. division of the jejunum from the duodenum). The complete rupture may be caused by a longitudinal strain.

If the injury does not cause an immediate perforation, it often causes bruising of the intestinal wall, which in conse-

quence of necrosis leads to a secondary perforation. This occurs the perforation is brought about by the necrotic membrane involving one layer of the intestinal wall (the mesentery is torn, the membrane separates the gut by extending along it etc.).

The situation of the perforation varies according to the site of the injury; the position and extent of the small intestine explains the fact that this portion of the gut is most frequently wounded; out of 219 cases cited by Petry and others it was injured 163 times.

Of the small intestine again perforations are most frequently found in the lower part of the ileum, and the upper part of the jejunum, less frequently the large intestine is ruptured, after this the stomach, and most rarely of all the well protected duodenum. Sometimes, as already mentioned a complete division occurs at the junction between the duodenum and jejunum.

The number and the characters of the perforations are naturally subject to much variation, according to the nature of the force which causes them and the condition of the gut at the time of the accident. Most frequently there is a single perforation. Yet, as in our cases, there may be two, three and, even more perforations and in addition to these there may be bruises and contusions which may assume the importance of primary perforations.

In addition to round perforations which look as if clean punched out, we find oval perforations, tears and longitudinal rents of various forms.

The edges of the wound are sometimes smooth and clean cut, but more frequently they are, irregular, serrated, ragged, the last especially when the rupture is due to bursting, the edges of the wound is caused by the direct compression of the gut, as for instance by the force of the blow squeezing it against the spinal column are often extremely bruised, and their prognosis is very grave.

In consequence of the contraction of the muscular coat the form of the opening is liable to variation. The prolapse of the mucous coat is a very constant feature, it was noticed in all our cases.

This protrusion of the mucous coat which probably takes place immediately and which may be of considerable size naturally prevents primary closure of the perforation.

Yet in a few lucky cases a perforation may heal, by adhesions to a neighbouring loop of intestine, the serous membrane of which has become inflamed, often the closure of the opening is brought about by the omentum. In the majority of cases however such adhesions are prevented by the escape of the intestinal contents and by peristalsis. And even if they have formed, peristalsis or the exudation of faecal matter, the varying conditions of the intestines, or the movements of the patient, may break down the fresh adhesions and separate the parts which have stuck together, so that the intestinal contents leak out into the abdominal cavity causing peritonitis and death, just as from an unhealed perforation only a little later (Case V.).

From the opening in the gut gas first escapes and is soon followed by fluid and more solid faecal matter, while the gas collects in the upper part of the abdomen and causes tympanitis and diminishes the area of liver dulness. The fluid collects in the dependant regions, mixes with the quickly formed peritonitic exudation and causes a scope of dulness of variable extent.

The escape of the fluid contents presents a special danger of its own, as it more easily and quickly penetrates to all parts of the abdominal cavity and sets up a diffuse peritonitis, while more solid matter is usually retained in the neighbourhood of the perforation and becomes encapsuled.

• By Dr. Adolf Schmidt, from the *Münchener Medizinische Wochenschrift* (Specially translated from the *Münchener Medizinische Wochenschrift* for the *Indian Medical Record*.)

The greater portion of spilled matter escapes immediately or soon after the appearance of the perforations later on, particularly has set in and there is paralysis of the peristaltic movements of the intestine, the intestinal contents escape in limited quantity, or not at all.

The direct subjective and objective phenomena arising from an injury to the abdomen from blunt force, are naturally extremely varied.

Many patients at first present almost no severe symptoms, although the intestines have been ruptured directly by the injury (cases III, VII, and VIII which is given as a supplement), they feel perfectly well and suffer no pain beyond what might be expected from the severity of the blow, they probably continue their work, walk home, and at the first feel nothing that would lead one to suspect a more severe internal injury.

In other cases on the other hand, immediately after the accident there is more or less severe shock; the patient has a drawn expression, there is exhaustion, complete apathy or great anxiety, consciousness may be lost.

In such cases the pulse from the beginning is small, weak, irregular, quickened, or more exceptionally slowed; the respiration is short, superficial, disturbed in rhythm (Uheyme—Stokes' phenomenon).

The absence or presence, or the degree of severity of the shock are not to be relied upon in the diagnosis of intestinal rupture, even in very severe wounds of the intestines the shock may be slight or altogether absent.

The presence of pain is a very constant feature and its degree and duration naturally vary with the nature of the injury and with the individual. In general the pain that is experienced immediately after the injury is not characteristic of wound of the intestines—it is selfevident that a severe blow on the abdomen causes pain,—Nevertheless a localised pain in the same place coming on spontaneously, or produced by pressure possesses a certain significance in the diagnosis, and I will consider this point later on—neither is vomiting, coming on soon after the injury characteristic. It may be due to the blow itself.

In addition to, and in connection with these subjective symptoms, in the severer forms of abdominal injury various objective signs appear which can be made out by percussion, marked abdominal tympanites, this condition however can be developed without the existence of a rupture of the intestines. Tympanites does not necessarily point to the escape of gas into the abdominal cavity, should it however make its appearance soon after the injury and especially if the liver dulness diminishes owing to an accumulation of gas between the diaphragm and the liver, then tympanites must be looked upon as a pathognomonic sign of intestinal rupture.

Dulness over the flanks occurring soon after the injury may point to escape of the fluid contents of the intestines into the peritoneal cavity, or to internal hæmorrhage.

In the further progress of the case a variety of symptoms will arise which will enable us to point with greater certainty to the nature and position of the injury that has been received, than we can possibly do from the above mentioned, early, and ambiguous signs; it must be clearly borne in mind that different organs may be injured by the same blow and that the symptoms of one lesion may be obscured and concealed by the more prominent signs of another.

Reverse intra-abdominal hæmorrhage may be suspected when the patient recovers slowly or hardly at all from the primary shock, when the collapse is more prolonged than one would expect from the nature of the injury received.

Swollen and increasing dulness in the deeper parts of the abdominal cavity is a symptom which points with great probability to internal hæmorrhage.

True, we have succeeded in demonstrating dulness in the flanks occurring soon after the injury when there was no severe hæmorrhage (cases VII and VIII supplement) but it is probable that in cases of hæmorrhage the dulness would increase and spread much more quickly than it would in cases of escape of the intestinal contents, even with the addition of serous and purulent exudation.

In hæmorrhage signs of collapse would soon be apparent, rapid anæmia, pallor of the face and body, the pulse is small, if it was good at the beginning it suddenly becomes small, frequent, weak, irregular or intermittent, the temperature of the body suddenly falls, a strong indication of internal hæmorrhage.

That signs of peritoneal inflammation may appear later on without any rupture of the intestines is known, the injury *per se* may set up traumatic peritonitis; this may be distinguished from infective peritonitis especially from perforation peritonitis by its relatively slower onset and milder course.

Perforation peritonitis which develops as the direct result of rupture of the intestinal wall and the escape of the infective contents of the intestines, assumes in its rapid course either the form of peritoneal sepsis, the poisoning of the body through the absorption of a large quantity of poisonous material, or the form of a true perforation peritonitis.

In the first case death from sepsis occurs very rapidly, often before there is time for any inflammatory changes to take place, the quickness with which the clinical symptoms develop in the second case depends,—apart from the quantity of the intestinal contents that has escaped,—upon the nature and virulence of the micro-organisms which may be present in the intestines.

The micro-organisms which are found to be the most frequent causes of infection are the *Bacillus Coli Communis*, *Staphylococci* and *Streptococci*.

Nevertheless the course of perforation peritonitis presents certain variations, according as it appears quickly and develops rapidly with only a short interval between the shock and its occurrence or more gradually, though still quickly attaining its full typical form. When the first disturbances arising from the injury have passed off, it may happen that one or two days pass before severe signs of peritonitis appear.

The symptoms are well known, one of the first and most prominent is the occurrence of, or the increase of already existing, meteorism and tympanites in consequence of which the liver dulness is pushed up, or completely destroyed. Hand in hand with this we have increasing pain in the abdomen which may extend to every part. Yet it is important to note that the most severe pain may be localised in a circumscribed area. Vomiting comes on early, first the contents of the stomach, later on bile stained matter, when the injury is high up the vomit may be mixed with blood.

Fæcal matter and flatus cease to be passed, and, as in most of our cases, the patient is unable to empty the bladder.

The temperature is as a rule, though not invariably, much elevated, the respiration is superficial, short, laboured, and a characteristic and rarely absent sign is the small, rapid, weak and irregular pulse. Next the agitation and restlessness of the patient increase, he rarely becomes unconscious, and the expression of his countenance (*facies abdominalis*) betrays the torments which he suffers.

This is the usual course of events in rupture of the intestines accompanied by escape of fæcal matter.

In very rare cases the rupture of the intestine is caused by adhesion, or by the action of a long-standing tumour, and may result with the rupture of a blood vessel. As a rule however these lesions break down later on to abscesses of their contents, arising from the peristaltic action, by vomiting, or by the movements of the patient.

When this happens signs of the acute perforation peritonitis suddenly appear, it may be several days after the injury, during which all symptoms were absent.

An interval of this description is in the highest degree characteristic of that form of peritonitis which is caused by secondary rupture of the intestine as a consequence of bruising and contusions resulting from an injury, or—as more frequently happens and is borne out by our observations—through spontaneous injuries of other internal organs.

Such lesions and contusions of the intestines, and likewise incomplete lacerations of continuity, such as tears of the serous or muscular coat, naturally present the same direct effects at the injury received (shock, pain, vomiting etc.) as are seen when the rupture is complete; they may also heal completely after the appearance of these symptoms, and in this case their presence can only be suspected from the occurrence of diarrhoea, stools containing blood or fragments of torn mucous membrane, local tenderness and some tympanites resulting from paralysis of the injured portions of the intestine.

These symptoms are however present in a minority of cases only.

As in only natural abscesses sometimes form in the bruised portion and lead to narrowing of the lumen of the gut.

Sometimes however the injury runs another and more severe course. While the wall of the intestine in its normal condition provides an effective barrier to the passage of the infective micro-organisms which are known to be present in the gut, it is quite possible that the bruised portion of the intestinal wall, with its tissues injured and its nutrition interfered with, may permit their passage through it, and so give rise to an infection of the peritoneum.

Such an infection sometimes runs a mild course, because the exciting cause gains access to the peritoneal cavity gradually and in small quantities so that it is the more easily absorbed.

It is altogether a different matter when the injury affects the deeper lying tissues, causes extensive tears and leads to thrombosis of the vessels in the walls of the intestines, so that the bruised condition must lead to secondary necrosis, perforation and perforation peritonitis. In the cases we have operated on we have several times found, in addition to actual perforations, places bruised and contused in this manner, in particular extensive bruising was found in Case III.

In many cases they are clearly visible and tolerably well circumscribed, more frequently they are more extensive and the serous membrane is of a purple colour; when the lesions are more severe and deeper and when the operation is undertaken later, the colour is browner and the tissues feel dry and brittle. In these severe cases the serous membrane has lost its polish and the place is certain to undergo necrosis in consequence of the injury to the tissues and to the circulation, to which must be added the effects of penetrating micro-organisms.

In milder cases healing can take place after absorption of the extravasated blood, in the manner already described.

We have amongst our cases of abdominal contusions two cases (which we will communicate at another time) in which, although there was no primary rupture of the intestine,

some slight results of a perforation in certain of the intestinal wall and in the other of the stomach, perforations developed, and rapidly caused death.

In both cases it was impossible to diagnose the exact nature of the injury.

The early diagnosis of contusion and tearing of the intestinal wall is usually impossible and most frequently we must be content with a possible or probable diagnosis, for the primary symptoms directly caused by the injury are similar in all cases of injuries of the abdomen caused by blunt force.

The additional symptoms mentioned above (diarrhoea, blood in the stools, traces of torn membrane, etc.) are absent in the great majority of cases.

Should however a perforation result from the necrosis of the injured portion and peritonitis set in, we will have no difficulty in coming to a conclusion as to the cause.

In cases of internal abdominal hæmorrhage the diagnosis can be made more easily and more certainly, from the continuance of collapse, the sudden weakness, dizziness in the flanks which develops early and quickly, the weakness of the pulse etc. The origin of the hæmorrhage, if it be from one of the large glandular organs (liver, spleen, kidney) may be recognised in many cases from the character and the situation of the injury (as a blow over the liver or in the region of the kidney) Severe hæmorrhage may also be caused by wounds of the omentum and mesentery, the exact situation of which it is impossible to diagnose.

In such cases it is obvious that as soon as a severe internal hæmorrhage is diagnosed, laparotomy should be performed and the bleeding point sought for and secured.

The diagnosis of perforation caused directly by an injury is undoubtedly more difficult than the localisation of an intra-abdominal hæmorrhage; here where everything depends upon the diagnosis being made as early as possible, the subjective and objective signs which first appear are altogether unreliable, and naturally the symptoms which are common to all severe abdominal injuries are of little use in the diagnosis of a perforation.

Besides almost all observations show (The typical cases of Mac Cormac amongst others) and our own cases leave no doubt upon the point, that even in very extensive injuries with several perforations and much bruising of the intestines, all severe symptoms may be completely absent and even the subjective appearances very slight, it was especially noticeable that most of our cases even 12 and 24 hours after the injury stated that they felt well and experienced nothing particularly wrong with them.

In the absence then of the symptoms which are held to be specially characteristic, vomiting, meteorism, severe pain, alteration of pulse and respiration, it is evident that an early diagnosis is impossible.

But even the presence of a single important symptom is often unreliable, as for instance the early onset of severe meteorism occurring in consequence of paralysis of the intestines caused by the injury, this produces tympanites although there is no free gas in the abdominal cavity.

Of more importance is it when the general condition of the patient becomes aggravated, soon after the cessation of shock, if there is no hæmorrhage to account for it.

It is of importance in the diagnosis of intestinal perforation to pay attention to the nature and power of the force which causes it, putting aside the injuries which may be caused by such powerful agencies as being crushed between two railway wagons, the falling of heavy masses of stone, or the falling of the body from a great height, our cases show that perforation is most frequently caused by a slight and

the blow being given a circumscripted area of pain on the abdomen, the contents of the stomach and intestines.

When the above mentioned symptoms which are frequent in perforation of the stomach and intestines, vomiting, meteorism, tympanism, and the escape of gas from the intestines, and diminution of liver dulness (omental signs to which GLUCK refers) are present, attention may be observed, they are not always present, but in undoubted cases of rupture, and are frequently overlooked. They are particular clearness of the heart and respiratory sounds over the abdomen, the pulse quick in the beginning, slows down later on in a characteristic manner.

Regarding special aids to diagnosis the method advocated by MOTT is to be avoided, he recommends the patient to drink water, if this causes intense pain it is a sign of perforation. It is clear that this method is not only unsafe but even positively dangerous because in this way adhesions may be broken down and the contents of the intestines may escape through the perforation with the peritoneal cavity.

Further in cases of contusion of the stomach and of the intestines, severe pain will be caused by the contact of the water.

For the same reason SWAN's proposal, for the localisation of perforation by distending the intestines with water gas, must be rejected.

While according to MIKULICZ in some cases if the abdomen is punctured, the perforation may be made out by the nature of the offensive, or specially smelling gas which escapes, (he punctured in a case of suspected rupture of the stomach and the evacuated gas smelt strongly of alcohol) or if the exuded matter be aspirated the presence of focal matter or particles of food may point to the existence of perforation provided always that the intestine is not punctured.

According to our cases vomiting appears to have a diagnostic importance only when it appears and gets rapidly worse a certain time after the immediate consequences of the injury have passed off, for with shock vomiting is one of the direct results of the injury.

Even so however it can only be held to be a sign of peritonitis setting in, which is no proof that there is a perforation.

Regarding the importance to be attached to alterations in the temperature and pulse we have already spoken.

According to our observations a most important diagnostic indication is the occurrence of a circumscribed and sharply localised painful area the pain is often spontaneous but even then it is enormously increased by pressure, it even persists after the whole of the abdomen has become tender from developing peritonitis and may be situated some distance from the point where the blow impinged upon the skin, according to the direction of the force.

We now make it a rule to mark out on the skin of the abdomen the area of the localised painful spot as soon as a patient is admitted, in order to judge of its constancy.

Further in one case, we were struck by the importance of a sharply circumscribed zone with a tympanitic percussion note closely corresponding to the area of the painful spot, this was noticed very soon after the reception of the injury and was doubtless due to the escape of gas.

It undoubtedly happens sometimes in cases of perforation with escape of gas that general tympanitis and diminution of liver dulness does not occur instantaneously, owing to the natural divisions in the abdomen (omentum, mesentery) the gas must take a certain time to be generally distributed. On the other hand CHANNY states that very rapid obliteration of liver dulness is indicative of rupture of the stomach, for here the escape of gas is nearest to the liver.

The above mentioned symptom of a circumscribed tympanitic zone can of course only be observed if looked for soon after the injury, whether it is frequently or regularly present I cannot say, for it was only in our last case that we noticed it. It may well be worth looking for.

(To be continued.)

Current Medical Literature.

Pathogenesis of Chronic Nephritis.

THE starting point of the process, the site of the individual lesion and the extent and course of the disease vary according to the intensity and duration of the causative irritant, which if slight, merely affects the parenchyma but if severe, includes all the tissues, often to an equal degree. Though it is difficult to say why the disease still proceeds from acute to chronic nephritis, even when the exciting cause has ceased to act, or why the urine possesses a distinguishing urotoxic coefficient with an absence in the urine of toxins or microbes, SWANSON thinks that (1) the changes in the tissues often occurring simultaneously (2) arterio-sclerosis in the kidney may be the result of chronic inflammation, or it may be primary or may arise coincidentally with the inflammation (3) chronic nephritis, usually due to a faulty state of the blood may (4) arise from, or over the same cause as acute nephritis and (5) may end in a secondary granular atrophy or the change occurring (6) primarily in the interstitial tissue there may be (7) a primary granular atrophy or (8) chronic interstitial nephritis, or also (9) a contracting nephritis due to primary arterio-sclerosis, (10) closely allied to which is a contracted kidney due to a deficient blood supply from narrowing and aphasis, whether acquired or congenital of the renal arteries.—*Beri. Klin. Week.*

New test for Peptone in the Urine.

TO avoid the disadvantages complained of by SALKOWSKI that after concentration the coloring matter of the urine may not only conceal but also simulate the biuret test, E. FREUND dispenses with acetate of iron and phosphotungstic acid. He adds 8 to 4 drops of a 10 per cent. lead solution to 10cc m. of the urine previously acidified with acetic acid, boiled and neutralised with liquor potassae. He then filters and submits the almost colorless filtrate to the biuret test, which consists in rendering the filtrate alkaline and shaking it with dilute copper sulphate solution when a rose color appears. For this method he claims greater expedition and so sharp a reaction as to be able to detect 1 part of peptone or albumose in 12,000 parts of urine.—*Brit. Med. Jour.*

Temperature Relations in Apoplexy.

WHILE acknowledging that there are many rules and admitting the possibility of certain peculiar localisations of hemorrhages and softenings modifying the symptoms, Dr. DANA maintains that in the enormous majority of cases the facts hold good that (1) in cases of cerebral hemorrhage accompanied by hemiplegia, the temperature of the paralysed side is higher than that of the sound side, whereas (2) in acute cerebral softening from thrombosis or embolism, this difference of temperature which is a valuable means of distinguishing between the two conditions (i.e., 1 and 2) is not present. No matter how pronounced and severe the central disturbance in hemiplegia due to embolism, there is no perceptible disturbance of temperature, as is to be found in thrombosis, no matter whether the trouble is hemorrhagic or thrombotic but the tendency 'to rise' is much greater with the hemorrhagic.—*Lancet.*

Pretuberculous Enlargement of the Spleen.

As the result of numerous observations on prisoners under his care, TADDSONI concludes that one of the earliest signs

of phthisis is an enlargement of the spleen. The only initial symptoms noticed by him in several of his cases were anorexia, wasting, frequency of pulse, and enlarged spleen, and though sometimes there was nothing enough for physical signs in the lungs, still typical acute pulmonary changes in very shortly after.—*Br. Med.*

General Paralysis and Diabetes.

Dr. HOLSTEIN divides diabetic cases into three groups in their relation to general paralysis.—(1) Transitory glycosuria, so common in the neurotic and the insane has no etiological bearing on general paralysis (2) Glycosuria caused by general paralysis (3) True diabetes, causing general paralysis and frequently being associated with intense headache, vertigo, amblyopia and loss of memory. Under a continued course and antidiabetic diet the sugar decreases and the mental condition improves, but traces are often left in the form of slight facial paresis plus knee-jerks and difficulty in pronouncing long words. Thus supporting CHARPENTIER'S theory of the toxic origin of general paralysis or becoming as LANDSHUIMER calls it "diabetic pseudo-general-paralysis."—*Sem. Med.*

Treatment of Alcoholic Meningitis.

Treatment is to be instituted from the beginning of the disorder. If any signs of debauch are left, wash out the stomach and give a purge. Feed the patient liberally with hot milk given every two hours. Avoid whiskey as a stimulant, but give strychnine gr. 1—10 every two hours. Apply ice cap to the head, and blisters to the nape of the neck. If the patient becomes comatose, tap the spinal cord. The author cites fifteen cases in which amelioration of the symptoms occurred after tapping. BY Dr. CHAS. L. DANA.—*Post Graduate.*

Value of Saliva from Infancy to Manhood.

Dr. W. G. A. BONWILL, of Philadelphia, said that he had noticed that nipples for infants' bottles are so long that they get under the infant's tongue, that they collapse readily and then no milk is delivered, and that the perforation is of such irregular size that the milk flows irregularly and usually too freely, so that no sucking is necessary and no saliva is secreted. To regulate the flow he has had a secondary nipple with a perforation of regular size introduced within the outer nipple, and the latter is made short and of a form much like a woman's, so that the infant must use its buccinator muscles in sucking, to obtain the milk, thus causing a flow of saliva and aiding digestion.—*Phil. Med. Jour.*

Enuresis in Children.

Dr. HAROLD WILLIAMS divides all cases of enuresis in children into two classes: (1) Those of local origin, such as malformations, etc. (2) Those of functional origin, due to seven factors: (a) undue excitability of spinal centres; (b) anemia; (c) reflex irritation; (d) direct volition—cold, fear of the dark, wilfulness; (e) auto-suggestion—the child having wet the bed, has been scolded and punished, and the habit assumes an immense and exaggerated importance to his mind; (f) retarded mental development; (g) enfeeblement of the will, which may be due to neurasthenia or hysteria.—*N. Y. Med. Rec.*

SURGERY.

Treatment of Fractured Patella by Type of Steel Wire-Rope.

AFTER thoroughly exposing the field of operation instead of (1) Lord LISTER'S interrupted wire suture across the line of fracture. (2) BARKER'S vertical suture (of wire or silk) passed through the ligamentum patellae and brought out through the quadriceps tendon after passing under both fragments of bone and (3) BUTEN'S and (4) TWISS'S subcutaneous (3) suturing and (4) tying (all of which are open to serious objections and the risk of a crippled or flail joint) is strongly recommended by Mr. CHARLES B. BALL M. Ch., F.R.C.S.I., who operates as follows; (1) A horse shoe flap, whose lower end dips to 0.5 inch below the apex of the patella and its sides this same distance from the lateral edges of that bone, is raised in front of the knee joint, (2) the knee joint is opened and (3) the periosteum incised, raised and reflected with the membranous connection between the cartilaginous surface of each fragment, (4) any irregularities on the osseous surfaces are smoothed down with a chisel, but not sliced, (5) A rope made of 8 strands of very fine steel wire closely twisted together and properly annealed just before using so as to render it thoroughly aseptic and more easy to adjust, is passed thorough the quadriceps muscle just above the upper edge of the patella and the protruding ends are (6) next passed through the tendinous expansion at either side of the upper fragment and brought out at the level of the fracture, (7) The lower fragment is similarly treated. (8) Minute incisions having been made under the loops at each of the corners to allow the wire to sink into the tissues, the wire is tightened by twisting together the ends of the wire rope on both sides of the bone. (9) When all is firm the twisted ends of the wire are cut short and hammered smooth, while the periosteal flaps are sutured together over the line of fracture and (10) a back splint applied after closing the external wound. Healing takes place pretty rapidly and a perfect joint results. A similar method, supplemented by horizontal perforation of the ulna for the reception of the lower rope, is suggested for fractured olecranon.—*Practitioner.*

Treatment of Conjunctival Affections by Argentamin.

AFTER years of patient search for a remedy that could not only be employed with ease in various conjunctival affections, but would also combine disinfection of the eye and the contraction of its vessels while exerting a minimum of irritation, Dr. JOSEF IMRE found just what he wanted in Argentamin or Ethylenediamine silver phosphate, which does not precipitate with fluids containing sodium chloride and neither burning nor itching retrogrades hypertrophied tissues and cures conjunctivitis, catarrhals, blepharitis, trachoma, corneal ulcer and iritis much more rapidly than does silver nitrate. He found that argentamin does not enter into combination with the albumen of the tissues and except in a few cases where he used it as an irrigation or as eyedrops, IMRE usually painted the affected parts 4 or 5 times daily with a brush dipped in the undiluted solution and obtained excellent results.—*Med. Age.*

Electrolysis of Small Growths.

Is strongly advocated as a "quick, safe, painless, aseptic bloodless and ideal method" by Dr. BARNETT who used it to remove corns, warts, moles, plaques, papillomata, nevi, epithelioma, condylomata, superfluous hairs, osteomata etc. In nervous patients he uses cocaine topically after which he pierces the growth with a needle held firmly in a needle-

INDIAN MEDICAL ASSOCIATION

ESTABLISHED AND REGISTERED 1894.

OFFICE AND LIBRARY:

50, Park Street, Calcutta.

TERMS OF MEMBERSHIP

Every man or woman, who being duly and legally qualified to practice medicine, by virtue of holding a degree or diploma or qualification in medicine, whether British, Indian, Colonial, European or American, whether from State Institutions or Independent Medical Schools, and every person holding a Government Certificate entitling such person to practice Medicine in any official or private capacity, shall be eligible for election to Membership in the Association.

Every person desirous of becoming a member, shall send an application in the form given below, to the Secretary of the Association, and the Council shall consider and dispose of same at their next meeting. On any person being elected a member, an intimation to the effect shall be notified in the Journal of the Association, and on payment of the subscription, a certificate of membership shall be issued.

Application for Membership.

I, _____, residing at _____, am desirous of being elected a Member of the Indian Medical Association; and I agree to pay the subscription, and to conform to the Rules and Regulations now existing, or which hereafter may be made by virtue of the same.

Name..... Address
Professional title Date

Every Member shall pay a subscription of five rupees per annum which shall entitle him to all the privileges of membership. The subscription shall be considered due in advance on the 1st January in each year, and should be forwarded to the Treasurer.

The *Indian Medical Record* is the Journal of the Association, and is the medium of communication between Members of the Association. In it shall be inserted the Transactions and Proceedings, and all notices of meetings of the Association, and any other business which the Council deem necessary.

The Reading Room and Library of the Association are open to all members of the medical profession from 10 A.M. to 5 P.M. daily (except Sunday.)

Members who have paid their subscription to the Association, may now obtain their membership certificates and copies of the First and Second Annual Reports of the Association by applying to the Secretary. Name and address to be plainly written.

Officers and Council:

President:—Isl Madhab Mukerji, Rai Bahadur, L.M.S., F.C.U., Principal, Calcutta Medical School.

Vice-Presidents:—(1) E. W. Chambers, L.M.S., L.S.A., Lond.

(2) H. H. Sir Bhagwat Sinha, G.O.I.E., M.D., C.M., F.R.C.P. Edin., L.D.S., D.O.L. Edin., Thakore Sahab of Gondal, Kathiawar.

Members of Council:—Representing Bengal and resident in Calcutta (4 members).

1. E. W. Jones, M.D., M.R.C.S., Eng.

2. J. G. Anderson, M.C.S.

3. K. G. Sircar, M.B., L.R.C.P., Edin.

4. Rakhal Das Ghose, L.M.S.

Representing—

5. **Bombay:**—Alfred McCabe-Dallas, L.M. Dub., L.R.C.P. Irel.

6. **Madras:**—C. G. R. Naylor, M.R.C.S., L.R.C.P., Lond.

7. **Central Provinces:**—Mirza Karim Khan, M.B., Edin.

8. **Punjab:**—Professor C. C. Ditch, M.B., M.A.

9. **Calcutta, P. and Oudh:**—John Morten, M.D., L.R.C.P., & A. Edin.

10. **Burma:**—N. N. Parakh, L.S.A. Lond., L.F.P.S. Glas.

11. **Independent Native States:**—A. Mitra, Rai Bahadur, L.R.C.P. and S. Edin.

12. **Assam and Duars:**—Wm. Brown, M.B., C.M. Glas.

13. **Representative of Military Assistant Surgeons' Service:**—Surgeon-Major James Forsyth, S.A.S., H. E. The Viceroy's Staff.

14. **Representative of Civil Assistant Surgeons' Service:**—Hari Datt Pant, L.M.S., Assistant Civil Surgeon, Gonda, Oudh.

15. **Representative of Hospital Assistants' Service:**—J. M. Philip, C.M.S., Government Ophthalmic Hospital, Madras.

Treasurer:—Surgeon-Major H. O. Hodgkin, S.A.S., Medical College, Calcutta.

Secretary:—James R. Wallace, M.D., F.R.C.S., Editor, *Indian Medical Record*.

Solicitors:—Messrs. Dignam and Co., Attorneys-at-Law, High Court, Calcutta.

Bankers:—Messrs. Grindlay and Co., Calcutta.

RULES AND REGULATIONS

INDIAN MEDICAL ASSOCIATION PROVIDENT FUND

I. The Fund shall be called the Indian Medical Association Provident Fund.

II. The Fund shall be registered under Act XIII of 1860, and the Registered Office shall be situated in Calcutta.

III. The object of the Fund is to give members of the medical community in India and Burma an opportunity of making provision for their families on the mutual benefit system.

IV. Any medical man or woman, may become a member of the Fund.

V. The Fund shall consist of two classes of subscribers, namely, (a) those who are members of the Association called Associate members, and (b) non-members of the Association called "non-associates." The subscription in each class shall be as follows:—

(a). Every non-associate shall, on joining, pay an entrance fee of Rs. 10, which shall be credited to the capital of the Fund.

(b). An annual subscription of Rs. 6 shall be payable by every non-associate member which shall go to meet the working expenses of the Fund.

(c). Members of the Association will pay no entrance fee and no annual subscription. They will pay only their fee of Rs. 5 as members of the Association and the "calls" of rule (d).

(d). On the decease of any member, a call of Re 1 per head will be made on all the other members of the Fund of both classes.

(e). To meet such calls, members of each class shall place in deposit in the Fund, a sum of not less than Rs 3 at a time, to be renewed before the last rupee on hand has been paid on his account.

(f). Notice of the payment of a call shall be given by a post-card, and through the *Indian Medical Record*, which shall contain a statement of the sum paid on account of the member to whom it is addressed, and of the balance to his credit held in deposit in the Fund, and this shall be deemed a sufficient receipt for the payment of the call.

VI. The nominee or nominees of each subscriber shall, at his death, receive a bonus calculated at the rate of Re 1 per head for each and every registered subscriber of the Fund, and who has a deposit in the Fund to meet the call.

VII. The claims of nominees in each class shall be paid as follows.—One-half on submission of certificate of death and surrender of entrance certificate (Rule X) and the remaining half, in accordance with the terms of Rule VII, after the claim is admitted by the Directors in meeting.

VIII. Applications for admission to the Fund must be made on a prescribed form which shall contain clearly written:—

(a). The full name, age, and address of the applicant

(b). The class he wishes to join.

(c). An engagement on his part to submit to and abide by the rules of the Fund.

(d). The name, age, and address of the nominee or nominees for whose benefit he joins the Fund

(e). And in the case of nominees who are minors the names and addresses of two or more guardians other than the subscriber, appointed in each case, to whom the bonus will be paid.

Every application must be accompanied by the entrance fee specified in Rule V (a), or by a postal money order or cash as subscription and "call" deposits due from associate members.

IX. A certificate of membership in the form prescribed shall be issued to each subscriber by the Secretary and Treasurer as soon as his name has been registered. This certificate may be renewed in favour of a fresh nominee on payment of Rs. 8 and surrender of original certificate. On a like payment being made, a duplicate certificate may be granted when the original is lost or destroyed.

X. Claims for payment must be submitted on a prescribed form containing a certificate of the death of the subscriber, signed by a duly qualified medical practitioner, magistrate, or a minister of religion. Payment shall be made

according to priority of application, on a formal notification of the nominee, who shall be required to surrender the entrance certificate granted under the preceding rule.

XI. Every subscriber shall keep the Secretary and Treasurer of the Fund duly informed of any change in his address. If he fails to do so, he shall have no cause of complaint against the Fund for any disadvantage arising from such neglect.

XII. Any subscriber who fails to renew his deposit for payment of calls before it has been exhausted, and so cannot meet a call under Rule V (d) nor the subscription specified in Rule V (b or c) within the year for which it is due, shall, after reasonable enquiry, be adjudged a defaulter, and shall forfeit all claims upon the Fund. Nothing in this Rule, however, shall prevent a subscriber, whose name may have been struck off as a defaulter from joining the Fund as a fresh member on payment of all arrears.

XIII. The Fund shall be managed by a President and three Directors resident in Calcutta, nominated by the Council of the Indian Medical Association from amongst their own members.

XIV.—An Auditor, who shall be a Councillor other than a Director, shall be elected annually by the Council, the accounts being submitted to such Auditor quarterly for audit.

XV. The half-yearly Report of the Fund shall be published in the *Indian Medical Record*, after it has been placed by the Directors before the Council of the Indian Medical Association.

XVI.—The Annual Report of the Fund shall be placed before the annual meeting of the Indian Medical Association.

XVII.—Any member of the Fund having a grievance against the Directors or Treasurer of the Fund may appeal to the Council of the Association for a consideration of his case.

XVIII.—The Directors shall meet once a quarter for the transaction of business, and shall have power to make, vary, or repeal by laws for the regulation of the affairs of the Fund, subject to approval at the next annual general meeting of the Association.

XIX.—All receipts, except sums credited to Working Expenses Account, shall be paid into the Bank of Bengal. When the sum accumulated in the Bank to the credit of Capital Account, in excess of the amount required to meet a call, admits of the purchase of Government Securities, an investment shall be made, and the interest obtained therefrom credited to Working Expenses Account.

XX.—When any question arises which, in the opinion of the Directors, should be referred to the whole body of subscribers, or which involves the repeal or alteration of or addition to, any of the rules of the Fund, the votes of subscribers shall be taken thereon, and the question so referred shall be decided by the majority of the votes recorded within one month from the issue of the circular.

FORM OF APPLICATION FOR ADMISSION.

TO THE SECRETARY AND TREASURER,

Indian Medical Association Provident Fund, Calcutta

DEAR SIR,

(Station) _____

I,

hereby apply to be admitted as (1) ^{associate} ~~non-associate~~ member of the Indian Medical Association Provident Fund, Calcutta, on behalf of my (2) _____

now _____ years of age, residing in _____ and I bind myself to submit to, and abide by, the Rules and Bye-laws of the said Fund.

I also agree that all claims on the above Fund shall be forfeited by my nominee, should I neglect to pay my dues.

I forward herewith Rs. _____

Yours faithfully,

Usual Signature and Address _____

(1) Strike out one word or the other in the blank space which you fill.
(2) Have state relationship. No interest will be allowed to a nominee unless two or more guardians appointed by whom the subscription shall be paid, the name and address of each guardian being clearly written on the back of this form.

(PLEASE WRITE CLEARLY.)

Guardians appointed for nominee named on reverse.
Name. _____ Address. _____

Dr. SMITH continued, "I have a feeling that we always used our superior forces and power to take the land that we wanted. It was allowable to do this because the land should be producing and partially supporting the tribe, the ox should be milked and the manure used for fertilizer."

Dr. Fanning would lay down as a rule that at least one-half of the head should have entered the uterine before forceps be applied.

MR WILLIAM PRINGLE said he had seen very serious damage caused by the use of the troops when the head was above the brim and the gun unlifted.

Dr. STARRMAN laid down the axiom that artificial extraction must never derange the mechanism of nature.

Dr. MILNE MURRAY maintained that flexion was favored by skin-traction forceps.—*Brit. Med. Jour.*

Remarks on Preventing Conception by Operation.

Arendt has suggested the propriety of producing artificial sterility by section of the Fallopian tubes through an anterior vaginal incision. Arendt refers to this as a very delicate proposition but sanctions the operation as justifiable under certain fixed conditions. Thus while Kehrer would resort to the operation in various constitutional disorders and certain inoperable diseases of the nerves, heart, lungs, stomach and kidneys, A. would restrict himself to purely local indications. A. calls attention to the immediate operative risk, to the dangers of narcoosis, and to the necessity of several weeks' confinement to bed. In advanced disease, therefore, in which pregnancy ought to be avoided, A. would advise his patients to resort to the usual simple preventive methods. In cases, however, of pelvic contraction with a previous history of dystocia necessitating craniotomy or resulting in dead children A. believes that Kehrer's operation is justifiable.

Because of the dangers in subsequent labors known to follow the operation of vagino-fixation of the uterus, A has ligated the fallopian tubes with the object of preventing conception in cases in which this operation has been indicated. With but one exception—in which formalin catgut was used—A has successfully ligated the tubes in sixteen cases. In the single exception the woman subsequently became pregnant. For future cases he advises dividing the tube between two silk ligatures. In cases to be operated for the induction of sterility alone he would advise a posterior colpotomy. It is of interest to note that out of 15 operated cases only 2 complained subsequently of dysmenorrhoea.—*Post Graduate*.

Influence of the Menopause on the Kidneys.

At a recent meeting of the Paris Hospital Medical Society, a report of which appears in the *Gazette hebdomadaire de médecine et de chirurgie* for December 16th, M. LE GENDRE remarked that, while the influence of the menopause on the circulation and on the nervous system was well understood, but little attention had been paid to its effect on the renal function. He had observed several cases which had led him to the conclusion that the change of life sometimes disordered the secretion of urine, perhaps by provoking renal congestion and diminishing the amount of urine, thus depriving the organism of one of its excretories and leading to the retention of noxious substances that were normally carried off in the menstrual blood. A certain degree of self-intoxication might result from their retention. This was most apt to occur in women who were of a pronounced neuro-arthritic habit. The symptoms mentioned by M. LE GENDRE were a reduction of the amount of urine, sometimes moderate haematuria or transitory haematuria, often lumbar pains, nausea, vomiting, and intense oedema. They could be prevented, ameliorated, or altogether synoned by wet-cupping or leeching the region of the kidneys, leeching the cervix uteri, or general bloodletting, together with the use of diuretics, such as milk and theobromate. —*N. Y. Med. Jour.*

**PHYSIOLOGIST, PATENT
BACTERIOLOGIST**

Declaration of the Government

MR. J. C. CONNELL and **MR. J. C. CONNELL** presented a patient before the Academy of Medicine at New York on April 19th. The patient was the subject of exophthalmic goitre and she had been operated on by undergoing resection of the sympathetic. The results were as follows: First, a most important diminution of exophthalmos; secondly, lowering of the beats of the heart from 220 to 100 in the course of a week while at the same time the painful phenomena in the precordia disappeared; and, thirdly, there was no marked effect upon the goitre itself. **MR. C. CONNELL** and **GAUDIER** concluded from their observations that in cases of exophthalmic goitre when the tension is intense and continuous, when this is the only symptom, or when there is also exophthalmos, there is always the risk of dangerous symptoms supervening. In such cases section of the cervical sympathetic, which acts most probably by preventing the hypersecretion of the thyroid gland, is the best operation to do. At the same meeting **M. JOHNSON** read a paper on the Cervical Sympathetic in Epilepsy and glaucoma. He has performed this operation forty-six times. In epilepsy out of 35 cases, some unilateral and others bilateral, 15 had been kept under observation for from nine to eighteen months; 9 were cured completely and no untoward effects had been observed. In exophthalmic goitre total and bilateral resection had always been done. Four operation had been performed from fifteen to twenty months ago, and recovery was perfect in all. The tachycardia disappeared fairly quickly, the goitre got smaller and harder, and as for the exophthalmos it disappeared almost at once. In 6 cases of glaucoma the results were very valuable. When the glaucoma was simple and chronic the results were excellent; the sight improved and the pain disappeared. In one case where glaucoma had appeared after the goitre, bilateral and total resection had acted upon both these affections and a cure was the result. With regard to irritative glaucoma the results were much less satisfactory. Vision did not improve, although the tension in the eyeball became much less. Resection of the cervical sympathetic is, then, in the case of some patients a good operation and gives good results in a number of diverse diseases.

Very Delicate Test for Bile Pigment.

By Drs. KROKIEWICZ and BATKO.—The following reagents are necessary: (a) A one-per-cent. aqueous solution of sulphanic acid; (b) a one-per-cent. aqueous solution of sodium nitrite; (c) pure concentrated hydrochloric acid. The test may be made according to one of three methods:

1. To two cc. of the reagents (a) and (b), add from two to five drops of the urine, and shake; if bile pigment is present a ruby red color develops, which changes to amethyst violet upon the addition of one or two drops of hydrochloric acid.
2. To a few drops of the solutions (a) and (b), add an equal quantity of urine and one drop of hydrochloric acid, and mix; a deep violet color results.
3. Shake together in a test tube several drops of the solutions (a) and (b), and pour out; if five cc. of isotonic urine be added, the mixture turns ruby-red, changing to amethyst violet upon the addition of hydrochloric acid.—*Post Graduate.*

Etiology of Synchysis.

IN a very exhaustive article, Dr. VAN NISSEN shows the following conclusions:—(1) Syphilis is a chronic infection transmissible from the blood to the other tissues.

of the disease in the blood, which is the only way in which it can be cured. The disease is the most common of the group of diseases which are related to the higher organized animals, and is characterized by a general wasting and emaciation of the body, and even in the milk, saliva, sweat, and the excrement of syphilitic persons, is all signs of their disease; but (5) not at all to be found when the disease is complicated with other diseases (6) Syphilis is all the way to inheritable and communicable and (6) the detection of the syphilis germ in the blood is essential to differential diagnosis and the proof of the presence of syphilis which (7) is absolutely incurable and relative healing denoting only a latent state. Medical art has yet to find a certain cure for syphilis.—*Ale Va Victis*.

Effect of Exercise on the Hæmoglobin with Reference to the Value of Rest in the Treatment of Anæmia.

Has not before been definitely defined; but the following conclusions may be drawn from a very valuable paper contributed by Dr. WILFRED EDMONDS, whose investigations show:—(1) that everything that stimulates the production of hæmoglobin must deplete the system if the subject is anæmic and there be no recuperative return complement. Thus (2) while there is a normal day fall and night rise showing the destruction and regeneration of hæmoglobin (3) active exercise increases the extent of day fall and night rise and stimulates a slight overproduction of hæmoglobin; but (4) passive exercise diminishes the volume of the blood without influencing the hæmoglobin (5) Rest on the other hand removes the drain and reducing the extent of the day fall enables the constructive process to exceed the destructive and thus gradually builds up the store of hæmoglobin.—*Brit. Med. Jour.*

Effect of Different Foods upon Height and Weight.

INCREASE of weight may be due simply to greater absorption of water by the body or to mere addition of fat says Dr. O. VOIT; but while MALLING HANSEN ascribes all direct causes of acceleration to internal forces and persistently declares that different kinds of food have no direct influence upon growth, the experiments of RUSNOW showed that of,

	CHILDREN FED ON Breast milk only.	Mixed diet.
The average weight in grammes at the end of 15 days was:—	8564	3525
And at the end of the year it was:—	9930	8480
While the increase per cent. of their weight in 15 days was:—	150.7	140.7

ORAMSEER, on the other hand, thinks that results favor artificial food though he admits that in the middle of the year breast fed children were heavier than those kept on a mixed diet. But for all that there is no positive evidence of the superiority of artificial food to mothers' milk and it is a well-known medical fact that increase of weight is no true criterion of an infant's healthy condition.—*Pædiatrics*.

Eosinophilic Cells in Tuberculous Sputum.

ARE considered highly important indications of (1) prognosis, (2) the patients power to combat the disease and (3) the therapeutic measures necessary. TRICHENELLER, says that though the eosinophiles appear months before the bacilli can be found they decrease greatly in numbers or entirely disappear as soon as the bacilli begin to assert themselves. They seem to indicate the progress and intensity of the disease as no eosinophiles could be found in 42 cases who had had pronounced symptoms.—*Centralbl. für In. Med.*

PUBLIC AND PRIVATE HYGIENE AND SANITARIANES.

An Individual Drinking Cup.

WARRANT for a separate cup for drinking purposes is suggested on hygienic grounds by Dr. D. L. LIGGETT of Bradford, Illinois, who thinks that the abolition of the "commune cup" in favor of the "solitary or individual drinking cup" would long ago have been complete had the lawmakers not "invaded the precincts of the holiest ecclesiastical institutions and threatened a new element of expense (both as to transportation and subsequent custody) that the feeble village and rural congregations are ill able to bear." He furthermore says, "and the *Indian Medical Record* some four years back, that every communicant should sip from a separate cup, and that every traveller and scholar, in public school or private academy should use an individual drinking cup; but as the expense of such an innovation appears to be the chief, if not in reality the only barrier to its universal adoption and as every body is not born with the traditional "silver spoon in his mouth," Dr. LIGGETT thinks that this difficulty could easily be overcome by replacing the solid silver, silver-plated, gold, tin, aluminium or glass cup, by others 'spun from wood-pulp or stamped from paper' that would not only meet all sanitary requirements, but would also be so cheap that even the poorest church communicant could easily afford to buy and keep one for his sole use. These cups could be made plain, or in fancy designs or laterally collapsible so as to be carried in the vest-pocket, while for communion service they could be arranged in cancellated or perforated trays of light wood or wire and after use be gathered up and consigned to the fire. To the public school pupil also and the traveller they would soon find their way and win their own commendation, since their cost would scarcely exceed or equal that of the paper plate and napkin (now so popular with tourists and picnicers) and would prove the easy entering wedge of a much needed, well-recognised and desirable sanitary reform.—*Jour. Amer. Med. Assoc.*

Moderate Drinkers.

It is the fashion with many prohibition cranks to abuse the "moderate drinker," the logic of their reasoning being that there would be no drunkards but for moderate drinkers. At first blush that argument appears sound, but when we come to investigate it a little more closely, we find that, like many another hasty generalization, it conveys a fallacy consequent upon inaccurate observation. The *British Medical Journal* for April 30th, commenting upon "a well-meaning appeal to the medical profession, issued by the Manchester and Salford Women's Christian Temperance Association, says: "The fact is that people take alcohol either because they like its taste, or because they like the effects which it produces. The former class seldom become drunkards, the later are inebriates from the beginning." This point of diagnosis gives us a means of rescuing from the ban at least one section of moderate drinkers—viz., those who drink chiefly, if not entirely, with their meals. There are many people to whom a full meal is absolutely devoid of any enjoyable qualities in the absence of some light form of alcohol, in the shape of beer, well diluted whisky, or light wines, such as are commonly taken in France and Germany. A light wine of that character, whose alcoholic strength is sufficient to produce any vasomotoric paroxysm of the mildest kind, even though a whole bottle should be drunk with a meal, is a great desideratum. There are many to whom tea or coffee is positively nauseous when taken with full meals of meat or highly nitrogenous foods, who dislike milk as equally insipid and unpalatable, and to whom water is no better than nothing at all. They are the legitimate moderate drinkers, who drink for flavor and not for

attention, but it is not a disease of the lungs, but a grave infection of the blood, and it is not a disease of the blood, but a grave infection of the blood.

Sewer-Gas and Diphtheria

It has recently been suggested that the inhalation of sewer-gas causes the development of diphtheria, although the bacilli cannot be cultured in this medium, since they are not changed by excretion from the fluids in which they are grown. It is possible that a non-virulent diphtheria bacillus may be present in the throats of many persons who inhale sewer-gas, the inhalation of sewer-air, because virulent and give rise to diphtheria in the throat. In order to determine this point, non-virulent diphtheria bacilli were grown in nutrient fluids in broth, and over the surface of the nutrient media air was continuously and slowly drawn by means of a water-pump. The only noticeable effect was a stimulation of the growth of the bacilli. Their numbers were not increased, as was proven by subcutaneous injections in guinea-pigs. These results are interesting, although they do not exhaust the question.—*Monthly Cyclo-gist.*

When may the Subjects of Gonorrhœa be Considered Cured?

THE JOURNAL OF PROSTITUTION for 16th April regards this question as of the gravest importance, because the compulsory treatment of the disease bears hard upon the patient, while the too early resumption is fraught with danger to the woman. It is unanimously recommended to have recourse to the "reaction of Meissner," which consists in producing an artificial irritation of the urethra by injecting some drops of a solution of nitrate of silver, whereby a secretion is caused which may be examined for gonococci. For the same purpose, the drinking of beer, the passage of bougies, etc., are recommended. Dr. DELPOSSÉ condemns these measures as not only without value, but actually dangerous by reason of the risk of producing cystitis, orchitis, etc. His method of procedure is as follows: Coitus is not permitted so long as there remain filaments in the urine in any number, or so long as the filaments are long and fall rapidly to the bottom of the vessel or contain gonococci pus organisms, or even many pus cells. When the filaments are short, few in number, slight, and floating, he directs the patient to prevent himself early next morning without having urinated since night, and having thoroughly fatigued himself on the preceding day. Pressure is made per rectum on the prostate, then the finger is drawn exteriorly along the urethra for its entire length, pressing firmly. At the same time, if necessary, a bougie may be introduced to afford a point of resistance. He collects from the meatus the discharge so obtained and submits it to microscopical examination; finally, the canal is scraped to a depth of two inches or two inches and a half from behind forward, and the scrapings are examined under the microscope. If these two examinations are negative he directs the patient to drink, during the following week, beer or champagne, to ride a bicycle, and to take long walks; then he makes another morning examination. If this proves negative, he sanctions coitus after a fortnight.—*N. Y. Med. Jour.*

Anticoin Poisoning.

FIVE cubic centimetres (500 units) were given as a prophylactic to a patient. Five days later urticaria, accompanied by malaise and chilliness, was observed. The eruption soon extended all over the body. There was prostration, vomiting, and oedema of uvula and pharynx. After thirty-six hours the symptoms moderated but by that time general glandular enlargement had developed which persisted for ten days. The same patient developed a treatment urticaria two years previously after an injection of 5 cubic centimetres of serum.—*Med. & Surg. Jour.*

attention, but it is not a disease of the lungs, but a grave infection of the blood, and it is not a disease of the blood, but a grave infection of the blood.

In the heart is an autonomic organ, and its action is governed by the ganglia and connections it has with the brain and spinal cord, and as heart disease and its treatment are subject to many changes, it is not a disease of the heart, but a disease of the brain, who points out that 'heart failure' really means 'brain failure'. Lack of nerve force shows that the entire principle of nerve almost immediately tones and relieves a weakened heart as well as strengthens it by increasing the power of digestion, while its action on the sympathetic nervous system causes (1) Augmented functional activity of all the muscles of organic life, (2) increased intellectual and muscular activity by excitation of the cerebral and spinal nerve centres, (3) an action on the protoplasm of the extremities of the sensory nerves whereby they cease to transmit impressions. Angina pectoris is caused by partial obliteration of the coronary arteries, anaemia by a variety of causes that weaken the heart by a deficiency of blood. In either of these cases a good heart-tonic is wanted and scarcely any better than acon whose action has been compared to that of strychnia, without however the danger of the latter. True nature will cure any diseased organ or tissues but she must be helped by proper food, time, judicious medication, wise expenditure of nerve forces and removal of the causes. These things being so, acon, supplemented with good blood—making food, should be more used in heart affections and heart failure from direct weakness and might, in many cases well replace the conventional digitalis, which advances the treatment of heart diseases no more than it was 40 years ago.—*Jour. Amer. Med. Assoc.*

Guajacotin and Eucasin.

WERE introduced as specifics in phthisis by ORTEL SCHROTTER and GOLDMANN but they have been proved at the Borough Hospital, Vienna, by KUBASTA who tells us (1) that while Guajacotin is free from the repulsive taste and smell as well as the irritant effect its substitutes, creasote, guaiacoli, etc., exert on the mucous membrane of the alimentary canal, it checks the night sweats improves the appetite and general condition and besides being useful in pulmonary affections such as pneumonia and pleuritic exudations, it acts as an efficient haemostatic in hamoptysis (2) As it is obtained from milk and contains 95 per cent of albumen but neither much nor extractives, Eucasin is particularly indicated in wasting diseases of all kinds as well as in gastric complaints from the readiness with which it is absorbed and its property of neither interfering with urate elimination nor forming uric acid.—*Med. Age.*

Calomel in Typhoid Fever.

Is claimed as an invaluable drug which Dr. STRAUSS finds (1) is free from danger often (2) directed against the seat of the disease by (3) being given in small doses hourly without interruption till the disease symptoms are controlled or till the germs become sore. In the early stages (4) large purgative doses will either abort or modify the disease or dissipate profound toxæmia and he notes (5) that the course of typhoid is shortened and graver features avoided by the systematic administration of calomel.—*Quint. J. Med. Sci.*

Potassium Permanganate in Opium Poisoning.

Dr. L. N. GOSVAMON, gives the following directions: 1. When you find that opium, in the form of its alkaloids has been taken, give a hypodermic injection of solution of 10 grs. of permanganate of potassium in 100 ccs. of water, at short intervals.

1. Wash out the stomach with warm water, repeating frequently for several administrations.

2. Then mix the stomach with a solution of permanganate, 10 grains to the pint of water, until washings come back pink, repeating this solution one minute each time.

3. Strain handful of solution of the potassium permanganate, 10 grains to the pint of water, every half-hour till recovery.

4. If patient is unable to swallow, use the stomach-tube with a large lower opening, and through the nose if necessary. Do not forget your rectal speculum (for dilatation of rectum); it may be of great benefit at critical moments.

5. In case of failure of heart and lungs, use artificial respiration and your hypodermic of strychnia.

The permanganate of potassium is not a poison, but is a local irritant; therefore use a large quantity of a weak solution, rather than a small amount of a strong solution.—*Cal. Med. Jour.*

Spermin in Diabetes.

DR. A. TSLNICHIN reports his own personal experience in the subcutaneous injection of spermatie fluid on himself in traumatic diabetes, under the direction of his physician, Dr. LITKIN. The spermatie fluid employed was prepared personally by the author and Dr. LITKIN from the testicles of bulls and dogs

THE O. D. ACTS IN INDIA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—With your permission I should like to make a few comments on a "Medical Man's" reply to my letter in your issue of 1st September.

He accuses part of my letter of irrelevancy, because he says—"It has always been considered necessary to draft a special act for dealing with venereal, which shows that there is no intention of trying to deal with it on precisely the same lines" (as other diseases). Can it be possible that a "Medical Man" has not grasped the fact that this time the government have not considered it necessary to draft a special act, but have modified the Cantonment Rules, under the act of 1889, so as to include venereal diseases along with cholera, small pox, diphtheria and typhoid fever?

However, he has shifted his ground in this second letter, and has dropped that question in order to advocate a "special act" which is to deal with a "special class" He must, therefore, either consider that the present steps taken by the government are inadequate, or else he must expect, as many others are known to do, that the rules can be so worked with regard to these diseases, that they will be equivalent to the special and distinct legislation enforced in India in previous years. Thus it is quite clear to what measures a "medical man" refers, when he says—

"Such measures are more likely to succeed under the simple conditions that prevail in India, than in the large European capitals" "Simple" must be an adjective prefixed for the first time to any conditions of life in India, but the words "more likely" which precede, seem, if any thing, stranger to the ordinary mind, when used in connection with what has been a matter of experience for nearly a century in India. For ninety years India has seen "the strongest repressive measures" brought again and again into force, only to be dropped in a few years as useless, to be once again resuscitated in a few more years, as at present, by a new generation of officials, who forget or ignore previous failures. To show this more exactly, between 1864 and 1887 Regulation was in full force in India, and the measures, which were put in operation, were such as a "medical man" would probably consider "likely to succeed," and what was the result? During this time the rate of admissions for venereal disease rose from 255 to 361 per 1,000. The condition of things was such that the Army Sanitary Commission in their report for 1877 ask, "If these facts are in any sense to be accepted as a success for the present protective machinery what kind of facts would indicate a failure?" The same body in their report for 1883-84 say again, "all the past experience shows that none of the methods hitherto adopted for dealing with them (i.e. the diseases) appear to have made any material impression on their amount." Well might Sir ARTHUR HONE, (K.C.B., V.C., Surgeon-General and Principal Medical Officer, British Troops in India) say in an official despatch dated 9th June 1882, "It is surely obvious that failure after seventeen years application means nothing more nor less than the hopeless inadequacy of the measure to effect

the proposed establishment. In any case it would be as hopeful to try to "stamp out" a will-o-the-wisp, as to "stamp out" venereal disease in a cantonment by the machinery of the registration and segregation of a few women called prostitutes, out of a multitude of unchaste women."

These quotations bring me to two points in your correspondent's letter, which seem to point to his ignorance both of historical and present facts.

He considers the action of the government in "facing such an unpopular and unpopular task" to be conclusive evidence of the necessity of the measure. Perhaps he may now realize that the action of the present government is not an isolated instance; former governments have manifested similar zeal, but have been driven to acknowledge their failure, and to repeal the "unsavoury measures."

But it was my last quotation, which speaks of a "multitude of unchaste women," that must seem to "a medical man" to militate against his special separate and distinctive class which "chiefly fosters and spreads venereal disease." Let one venture to refer him to a despatch from Lord GEORGE HAMILTON to the Government of India, dated 26th March, 1896. There he will find stated in paragraph twelve that there exists a general concurrence of opinion, that a large number of cases of venereal disease originate with the low class of women who frequent the vicinity of the barracks after dusk.... whatever may be possible should be done to diminish the number of women employed in various work about the soldiers' barracks. Nor is this a solitary mention—a report from Surgeon Major BARCLAY, in 1885, pointed out the increase of these diseases in the "relief" (winter) season, when the troops were continually moving about, due to clandestine prostitution with the country women. Again, the Army Sanitary Commission, reporting on the Madras Hospitals, speaks of the fact that the regulations "do not include all classes (note the plural) from which infection may come," while another part of the same report states that "to keep down clandestine prostitution would require a degree of zeal and hourly watchfulness never likely to be carried out." Many like paragraphs could be quoted, such as the report of the Bombay Sanitary Commission, which speaks of "women in the fields," (the country women mentioned above) and "along the roads to the cantonment," quite different classes from the women of the Lal Bazaars, including, as is said elsewhere, "female punkah coolies, grass cutters and others."

I cannot help suggesting to your correspondent a wider range of reading in governmental reports and elsewhere; since he expressly states that the existence of this separate class, is to him the most important fact of all, it seems strange, that he is not in possession of the ordinary facts of the case, at least in this branch of the subject.

Finally, your correspondent says that if the Paris system were unsuccessful, it was because the "administration was not up to its work," and he would doubtless give the same causes for failure in the past in India. It would be interesting to know if he has any suggestions or plans ready, such that would enable past difficulties, extending over a long period of years to be easily surmounted in the future?

Yours &c., X. Y. Z.

SCANDALOUS NEGLECT OF P. M. O'S IN THE ARMY IN INDIA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—You have done the Local Medical Services a service by exposing the corruption to which Head Clerks are addicted in the P. M. O's offices of all three Presidencies, and it is to be hoped that those who hold communications from these men asking for "25 pills" or for "a hundred pills to be distributed amongst the people as they will do a lot of good" will send them to you to make use of. Very often the handwriting is feigned, but the address, tenor of the requests and allusions made, lay matters pretty bare. The late removals during the frontier business led to a lot of money changing hands, and not a few Hospital Assistants have been fleeced without obtaining what they wanted. Others again have given so much as 80 and 100 Rupees to escape Field Service. The men were nominated by the Command Office, or by the P. M. O., in India, yet have managed to evade going, through the District P. M. O. Baboo's juggling. Your former correspondents are correct in saying that this is known to officers of the service, for, no sooner a Native Army Hospital Corps man is warned or punished he begs for a few days leave, and the invariable remark by his Commanding Officer is "I expect he wants to find his way to the P. M. O's Baboo to get away from this." Long before official orders are received in a Station Hospital, a ward servant is able to tell one where he is going to, in fact, he is prepared to move on receipt of the order because he has had "khubber" days before, having "squared" the Baboo himself or through a friend. Let the P. M. O. of the Bengal Command, for instance, call for a return showing the actual distribution of Warrant Officers and Hospital Assistants doing military duty in his command, and note how many of the temporary "subordinate charges" are in the hands of senior men—let him call for a register of all applicants for vacant subordinate charges and note how long they have been left unattended to. Perhaps he may find that senior applicants have been placed in charge of sections, (a panacea) while the "permanent sub-charge" is for the time being in the hands of a junior. Why? to gain time to "come to terms" if possible. Another procedure I have noticed, which is nothing but gross impudence done in the name of those in authority. When the P. M. O. of the Command is on inspection tour he is accompanied by a small office staff, the senior Baboo has the audacity to write to each Senior Assistant Surgeon about to undergo inspection, to "put him up," or make arrangements for his board and lodging. Often the Hospital Storekeeper is the individual who has to suffer. I have also seen a note addressed to "My Dear Mr. ——" "Please have an ambulance cart, with a ward servant and kahars, to receive the luggage at the Railway station. The P. M. O. will arrive by—train, and wishes these arrangements made." Of course, the "Senior" knows this is simply a lie, for no P. M. O. would order a Government Hospital Ambulance cart and a ward servant of the A. H. N. Corps with hospital kahars to convey his luggage from a railway station. If entitled to a government carriage he would indent on the Commissariat Department. Yet this is what has been done in

his name, and I am ashamed to say, complied with. The remedy lies with the P.M.O. in India and the E. M. O. of Commands. Stringent circulars should be sent to all station hospitals on the subject. All movements, transfers, appointments, leave etc. in the I.S.M.D. should be solely between the P.M.O. of Commands or Districts, direct with Medical Officers in charge of station, or other hospitals. P.M.O.'s of Districts should certify in their Annual Inspection Reports that all orders bearing on the transfer appointments and leave of Warrant Officers and Hospital Assistants should be promulgated by themselves in consultation with the R. A. M.O. officers immediately concerned. Nothing less than drastic measures of this sort will remove the scandal now under exposure. At the same time, the I. S. M. D. should be made aware once for all, that any man found communicating with any of the P.M.O.'s clerks on the subject of leave, transfer or appointments will be severely dealt with.

Lastly why not substitute senior assistant surgeons in Command Offices for Baboos? If they can be utilized on field service as P.M.O.'s clerks, why not in peace times in the Command Offices?

Yours &c., OLD SOLDIER.

(For the honor of the Military Medical Administrators of India and for the good of the local medical officers under their command, we most earnestly solicit the attention of the P. M. O. of the Forces in India to this utterly disgraceful state of affairs. We shall wait a reasonable time for official action in this matter—ED, I. M. R.)

AN ASSISTANT SUPERINTENDENT FOR THE HEALTH DEPARTMENT.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Apropos of Dr Cook's proposition, has it struck nobody that apart from the disinclination to afford work to any one who does not bear the Hall mark of British birth and training in England or the stamp of *Pishnu* or *Kali*, there is a distinct attempt to slow over Eurasians and to disparage the qualifications of present officers in the Health Department. As an argument in favour of his request for appointing a fourth Superintendent of Conservancy whom he thinks should be imported from Europe, Dr. Cook pleads his inability to come into "efficient contact with his ward Inspectors so as to teach them their work" and refers to the Budget for 1895-96 as proof that "one of the Superintendents was getting Rs. 400 per mensem plus Rs 50 horse allowance", but he forgets to admit that the Municipality has already given him *two* Medical Inspectors and an Assistant Health Officer with special sanitary and chemical qualifications to assist him in supervising and controlling the duties of 3 Superintendents of conservancy and 25 Ward Inspectors whose work carries them over 11 square miles of ground, which 4 Food Inspectors are considered more than sufficient to look after, and he apparently ignores the fact that the "one Superintendent" he specially refers to was the late Mr. GILBERT WRIGHT who years ago took up office as "Personal Assistant to the Health Officer" which designation was simply changed to "Superintendent, Southern Division, when in 1886 the Municipality engaged its first whole-time Health Officer, of course Mr. WRIGHT continued to draw his big pay till he was pensioned off, when I understand Mr. H. VINCENT was promoted to his place.

I quite agree with what *Capital* has to say about a clean sweep in the Municipality being necessary, and I think that the Imperial Anglo-Indian Association should inveigh on the Government to find a larger proportion of Eurasians employment in the Municipality, in the whole of whose enormous staff there are about 80 Eurasians of whom only 10, I think, are to be found in the 200 and odd hands that comprise the Health Department. If Dr. SIMPSON could get through 8 "beats" per morning in addition to his additional duties on the *Indian Medical Gazette*, the demands of the Microscopical Society and his other Health duties, why cannot Dr. COOK who has the Health work only to attend to, manage to do 6 wards daily and, making 7 complete tours per mensem of the town and suburbs succeed in giving each Ward Inspector 84 in place of the 12 lessons only that he expresses his ability to give in a year. Dr. R. SEN, the Assistant Health Officer and each of the Medical Inspectors and the three Superintendents could act similarly each day, and thus ensure every Ward Inspector getting 2 practical teachings for every morning in the year, and he could also receive theoretical instruction when he attended the Health Office for "reports" in the afternoon. There would also be the salutary result of the men being kept up to their work and complaints such as *Indian Engineering* exposes would soon cease to exist.

Eight years ago I made a suggestion which would have worked wonderfully well if it had been acted upon instead of being shelved indefinitely. Complaints rose on every side that the food supply was badly adulterated and the conservancy worse looked after, I wrote to the then Chairman suggesting that the Ward Inspectors be authorised to look after the food supplies while going through their several Wards, and that as an inducement to efficient work their salaries be increased by 20 per cent. while to prevent risk of corruption one third should be Indians, one-third Europeans and the remainder Eurasians, and that the Police system of monthly or quarterly shifts be employed. So that race feeling would make the one lot watch the others, while their frequent changes would accustom them to the requirements of every ward and prevent their becoming too friendly with the resident rate-payers and food vendors. All this could have been done and far better results arrived at than now obtains, at a cost of nearly Rs. 40,000 less per annum, than is now expended on the Health Department.

Similar remarks could as aptly be applied to other departments of the Calcutta Municipality, which is incessantly howling about increasing expenditure and decreasing reduction of rates, but is at the same time cutting its own throat and damaging its interests by making the Christians give way to Indians who for the most part live in joint houses paying *single* rates and clubbing together to reduce menial (ie household) establishment, and starve hundreds of folk.

Were the *Record* a purely political instead of Medical Journal I could adduce oceans of irrefutable evidence that the practice of replacing Europeans and Eurasians by Indians is a suicidal policy that depletes trade, ruins the currency, impoverishes India and rushes the crime lists up by bounds.

That the Imperial Anglo-Indian Association should see to this as soon as possible is the honest and well-meant advice of,

Yours &c., R. G. S. C.

MEMBERS OF THE INDIAN MEDICAL ASSOCIATION

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—With you kindly find under the following letter from the Indian Engineering Association.

"Microbes in the brain is the epidemic under which in these ways humanity, at least in India, is now suffering. You pointed out the other day the peculiar effect which this disease seems to have produced on the logical faculty of an eminent microscopic luminary in the official statement at Agra. True and again we, as well as some of your correspondents have pointed out the external effects in one direction which this disease has produced on the minds of the Powers that be at Darjeeling. All India is aware only too sadly and too well of the particular phase this disease assumed in the case of the eminent fraternity attacked by that variety of the microbe known (?) as the plague bacillus. In all these the one effect seems to be a curious suspension or displacement of the logical faculty. In Agra one luminary condemned water as not potable which contained fewer microbes than others which contained more! In Darjeeling the subjects of the disease have persisted in forcing on the unfortunate inhabitants water, which such an eminent expert as Surgeon-Major BANNERMAN, had conclusively shown to have been by a costly process brought into a condition more congenial to microbe propagation than nature had intended. In Bombay a virulent attack on the brain of microbe of the plague variety resulted in widespread discontent, riots, dislocation of business and other concomitant evils, while, if we may judge by results, they concurrently appeared to have had the further effect of enlarging the field of microbic activity, till a return of health to the ruling powers restricted the mischievous activity of these pests by wiser regulations. In Bengal the results in Calcutta are well known; here however, thanks to the strength of constitution of our Provincial Governor, the disease failed in its attacks on him, with the consequence that the measures actually taken to restrict the field of activity of of these microscopic organisms differed so greatly from those followed in Bombay (and advocated by the luminaries here suffering from microbe on the brain), that they actually succeeded in their object; but the disease here took an unexpected and wholly unforeseen turn—it induced its eminent victims to "jubilate" and "liquor up!" This particular rare and amiable symptom of the disease appears to be well worthy of study by the Medical faculty, and might well occupy the attention of biologists and physiologists! In Madras although the plague variety of the bacillus has found no firm footing, the less mischievous ones of the Darjeeling filter variety seem to be in a fair way of finding scope for their activities!

Unwarned by the researches of Surgeon Major BANNERMAN, which have demonstrated that the water in its natural state in Darjeeling actually contains less microbes than after passing through the particular sort of filter patronised by Darjeeling—that the filter forms a sort of breeding ground for these microscopic pests, and that the measures there adopted to purify water are not only inefficient but expensive besides, Madras has been seized with the mania of repeating the experiment by patronising that particular form of filter. There is none so obstinate as he who will not see!

The public meanwhile have to pay the piper and to grin and bear it."

Yours &c., D. P. H.

GRIVANCES OF MADRAS HOSPITAL ASSISTANTS

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—As a member of the Indian Sanitary Department, I note with extreme satisfaction and pleasure that through the great active interest exerted by the Indian Medical Association and yourself, the grievances of Military and Civil Assistant Surgeons have been redressed and their pay and future prospects bettered.

I, however, regret to find that nothing has yet been said or done for Military Hospital Assistants although it has been repeatedly pointed out by you and others that the grievances of this despised class are undoubtedly real and are worth favorable consideration. This unfortunate class were no doubt eagerly expecting that their 'hardships' too would be considered and would be removed. How much has been actually considered, we are not aware of. But this much is clear—nothing has been done. This news was as might be expected received with such disappointment and utter despair.

We can easily see that the mental distress consequent upon disappointment must have been not a little, when we remember that this despised class are more hardly worked and more badly paid than their Assistant Surgeon brethren. It is well-known that the Military Hospital Assistant has the same duties to perform among native troops as the Military Assistant Surgeon among British troops. The former is qualified to do and hence quite competent to do that which the latter is required to. Nevertheless there exists an extremely marked and unreasonable difference between their respective salaries. After going through a course of four years' study in the Medical College, a Military Hospital Assistant—as he is called—gets a pittance of Rs 16 per mensem by way of salary, whereas his better styled Assistant Surgeon brother draws Rs 85 per mensem. There seems to be no sufficient reason for such a difference when the course of training for both classes is the same, and both have the same professional qualification and the same professional duties. Nay, in one respect the humble Hospital Assistant is superior to the Assistant Surgeon, viz., in respect of general educational qualification, for the poor Hospital Assistant must be a matriculate to find entrance into the Medical College, though the Assistant Surgeon need not be a passed candidate.

Many years have elapsed since the poor Military Hospital Assistants submitted their memorial praying for an increase of pay in the various grades of their service. They have not as yet been heard and there has been no response. Now that these "rejected many" have sought you for their redeemer I humbly hope that you will take up their cause, and represent to the governing body their just claims, thus enabling them to sit side by side with their Assistant Surgeon brethren, in whom the Government have found "a chosen few."

Yours &c., Y.

MADRAS, PERAMBUR, 11th October, 1908.

(The Indian Medical Association will shortly approach Government in the matter of Hospital Assistants' grievances.—Ed., I.M.R.)

EDUCATION OF MADRAS HOSPITAL ASSISTANTS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—In the minutes of the 15th Meeting of the Indian Medical Association, I read (Indian Medical Record 1st June 1908, page 407) the words "Much progress is required in the education of Hospital Assistants."

As the Hospital Assistants' Department is a branch of the Medical Service, it is not subject to the same regulations as the other branches. I am not sure that I have the right to say that the Hospital Assistants' Department is a branch of the Medical Service, but I think it is. I am not sure that I have the right to say that the Hospital Assistants' Department is a branch of the Medical Service, but I think it is. I am not sure that I have the right to say that the Hospital Assistants' Department is a branch of the Medical Service, but I think it is.

However strongly the issues mooted on your page 457, above referred to, may hold good for Bengal, Mr. J. M. PHILLIP, B.M.S., the representative of the Hospital Assistants' Service, will readily bear me out that the preliminary education of Madras is in no way lower than that of Calcutta and that the Madras Hospital Assistants are required to pass in a four years course at the Medical College, where every branch of their studies, both practical and theoretical, is taught in English only.

On page 466 of the same issue I read, "In Bombay and Madras the Matriculation opens the way for the L.M. and S." Kindly permit me to correct this as it is not consistent with fact, since in the Madras Medical College youths are not allowed to study (as I hear they are in Calcutta) much more appear for the L.M. and S. examination, until they have passed the First Arts Examination.

As I do not believe the Indian Medical Association intentionally included Madras in the category of "Hospital Assistants who are taught in the vernacular languages only," I trust in justice to my Service you will kindly find room for this letter in an early issue of your valuable journal.

Yours &c, K. M. YUSUF

MADRAS.

(The Secretary of the Indian Medical Association stands corrected and respectfully apologises for this unintentional libel on Madras Hospital Assistants and the Madras Medical College. The fact that the educational and professional requirements in Indian Schools vary so much only prove the general faultiness of Government methods in India. Ed. I.M.R.)

AFTER NINETEEN YEARS SERVICE NO BLESSING AFTER ALL

TO THE EDITOR, "INDIAN MEDICAL RECORD"

SIR,—I see it stated in the *Record* dated the 16th October, that the Secretary of State for India has abolished the Rs 60 class of Military Assistant Surgeons and that the 200 class "will be attained after 19 years service instead of 24, the present average."

Since reading this I have amused myself in working out the averages for the three presidencies.

Bengal gives an average of 21 years and 3 months for the 10 years, 1888-97, Madras 19 years, for the 7 years, 1890-1897. Bombay 18 years and 7 months for the 7 years 1888-91 and 1893-97. None were promoted in 1898. I have excluded apprentice service and men who have received special promotion. It will be seen from my figures that Madras and Bombay men have nothing to be thankful for and that Bengal men very little, if anything, as the men of this Presidency who were promoted in 1897, had an average of 19 years and 3 months service.

Yours &c, SUBUTATOR.

A SUGGESTION FOR THE TREATMENT OF PLAGUE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Have any of your readers, especially those, who have the treatment of plague cases, ever tried the application of *Unguentum Hydragryi Nitratis* for the glandular swellings in such cases? I have tried it in about 50 cases and in every instance had favorable results, namely a gradual absorption in the case of the swelling, which finally disappeared, accompanied with a very marked lessening of the pain in the affected area.

As the Hospital Assistants' Department is a branch of the Medical Service, it is not subject to the same regulations as the other branches. I am not sure that I have the right to say that the Hospital Assistants' Department is a branch of the Medical Service, but I think it is. I am not sure that I have the right to say that the Hospital Assistants' Department is a branch of the Medical Service, but I think it is.

Yours &c, R. S. S. S.

Assistant Surgeon of Madras City.

SINGAPORE.

WHAT SHALL BE DONE FOR A URINARY FISTULA IF AN OPERATION IS REFUSED?

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—With you please or any of the numerous readers of the *Record* very kindly let me know what is the best method of treatment to be adopted in the case of urinary fistula, when recourse to instruments or even to the catheter is flatly refused by the sufferer.

The external opening of the fistula is in the scrotum and of about a month's standing.

The patient is gonorrhoeal.

Yours &c, "ONE OF THE PROFESSION."

(Massage with mercurial ointment over the tract of a fistula has recently been attended with good results but operative interference is necessary in most cases.—ED. I.M.R.)

Government Medical Gazettes.

GOVERNMENT OF INDIA.

Lieut.-Col. G. O. Hall, I. M. S. Bengal Estab., granted temporary rank of Col from 17th Sept. 1898.

To be Surg.-Col.

Brig.-Surg.-Lieut. William Edward Johnson, M.D., Madras Estab., 30th June 1898.

MADRAS ESTAB.—To be S. A. S. with hon. rank of Surgn.-Capt James Thomas Dodd, 9th Sept 1897.

To be S. A. S. with hon. rank of Surgn. Lieut. Charles George Roberts 9th Sept. 1897.

The following officers have retired from the service — Surgn.-Col. Sir George Thomson, K.C.B. 6th July, 1898.

Lieut. Col. Joseph O'Brien, M.D. 19th Aug. 1898.

Surgn.-Lieut.-Col. Kali Pada Gupta 29th June 1898.

Major Alexander Frederick Ferguson, 8th Sept. 1898.

The services of Capt H. D. Mason, R.A.M.C., are replaced at the disposal of the Mil. Dept. from 1st Oct. 1898.

The services of Capt. C. E. Stevens, M.D., F.R.C.S. I.M.S. (Bengal) are placed permanently at the disposal of the Govt. of Bengal.

Asst. Surgn. Udal Bhan, Impl. Estab. three months' privilege leave from 4th Sept. 1898.

The services of Asst. Surgn. Devindra Singh Otto, Impl. Estab. are temporarily placed at the disposal of the Agent to the Govt.-Genl. for Baluchistan for appt. to the Ry. Hosp., Sharigh.

Major H. R. Woolbert, M.B., I.M.S., Offg. Med. Officer, Kotah and Jhirapatan, one month's privilege leave, from 19th Sept 1898.

BENGAL GOVERNMENT.

Asst. Surgn. Behari Lal Pal, doing duty at the Presy. Genl. Hosp. leave for three months.

Asst. Surgn. Sasi Bhushan Banerjee, doing special duty in connection with cholera inoculations at Farukh, to do asphy. duty Med. College Hosp.

Asst. Surgn. Kali Prasanna Basu, a superny., at the Med. College Hosp. to Madaripur sub-divn and Diary.

Asst. Surgn. Rama Nath De, Madaripur sub-divn, and Diary, leave for three months.

PUNJAB GOVERNMENT.

Hosp. Asst. Nahi Bakshi, Sampla Dist. Subd. privilege leave for three months, 30th Sep. 1898.

Asst. Surgn. Duni Chaud. Rai, Bhiwani Dist. three months' privilege leave from 4th Oct. 1898.

Hosp. Asst. Raju Lal Jallandhar, to Adampur Dist. in that dist. from 1st Oct. 1898.

Hosp. Asst. Moti Ram assigned charge Jail and Lock-up Hosp. Rawalpindi, 2nd Oct. 1898.

ORIGINAL ARTICLES.

NOTES ON APPENDICITIS.*

By ALBERT CHATMAN, M.D. Lond., F.R.C.S. Eng.
 Surgeon to King's College Hospital, London.

During the last few years so many cases of appendicitis have come under my notice that it seems desirable to add here a few remarks on the subject, gathering together some of the more important facts that have been forced on one's attention, and endeavouring to define one's position as to the vexed question of treatment.

Not long ago the very name of appendicitis was unknown in surgical text-books; typhilitis, perityphlitis, and peratyphlitis were described in works on medicine, but the true characters of the affection were but little studied. At the present time there seems no reasonable objection to the new terminology, since there is but little doubt that the appendix is primarily at fault in the great majority of these cases. One does not in the least question that true typhilitis exists, and that it may lead to a series of complications, included under the name perityphlitis, almost identical with those arising in appendicitis, but the number of these cases is comparatively small.

It is extremely difficult to gain any idea as to the frequency of this affection, but that it is extremely common cannot be called in question. TORRI, of Copenhagen, stated some years back that he had found evidences of its previous existence in 85 per cent. of all bodies that he examined after death. The conditions that lead to it are very diverse, but it is evident that the old idea that assigned as its chief cause the presence of orange pips, grape stones, or other foreign bodies must be entirely discarded. It is only in a comparatively small proportion of cases that concretions are found; earlier writers stated that they were present in nearly 50 per cent., but this is much too high a calculation, MURPHY and TREVES both suggest about 30 per cent., but to my mind even this is too large a figure. These concretions are rounded ovoid bodies, rarely exceeding three quarters of an inch in diameter in their longest axis; they are usually laminated, showing that they have been old inhabitants of the appendix; they are formed of inspissated faecal material, held together by mucus, and often with a considerable addition of phosphate of lime. Occasionally a small foreign substance such as a grape pip forms the nucleus. It must not be forgotten, however, that even if one grants the existence of a foreign body in the appendix, we have still to explain why it leads to an outbreak of inflammation when it has lain in this situation for so long. Possibly the final attack is due to its gradual increase in size, leading to pressure atrophy of the walls, or probably some other factor has to come into play.

I have been much impressed of late with the role that is attributed to injudicious movements, strains, twists, &c., and to my mind mechanical conditions play a much greater part in the etiology of appendicitis than has hitherto been assigned to them. FRIZ, who has investigated this subject statistically, assigns about 10 per cent. of the cases to this cause, and TREVES, commenting on

these figures, states that he thinks them too high. My own cases have been, I fear too few to warrant any statistical statement; but certainly in a considerable proportion injury or some injudicious exercise had been present immediately before the attack, and might certainly have been an important accessory. Thus I saw last summer at Ramsgate, with Dr. PARKES of Rickmansworth, an architect who had been in bad health for some time, in consequence of dyspepsia and general asthenia; he had enjoyed a heavy meal of new bread and apples, and then proceeded to take part in a display of agility, consisting in jumping over chairs, forms, &c., and the same night a severe attack of appendicitis started. The ingesta to which the outbreak might have been attributed could scarcely have had time to bring it about. Certainly the effect of mechanical influences in determining relapse cannot be gainsaid; as a result of the first attack the appendix becomes bound down, probably at its apex, to some of the surrounding tissues, and the result of sudden exertion may be to stretch or tear these. This is particularly likely to follow if the appendix is placed posteriorly and contracts adhesions to the fascia over the psoas muscle.

The structure and position of the process also lay it open to inflammation from very slight causes. It is a degenerate organ, having practically no function in man, and being apparently of no use. It has, therefore, a very small blood supply, derived in the male sex from one single twig of the ileo-colic artery; in the female there is a small additional supply from the right ovarian trunk, and it is possible that this may explain the fact that appendicitis is nearly four times as common in men as in women. Then, again, the appendix is entirely surrounded with peritoneum, being attached to the omentum by a definite mesentery or meso-appendix, and hence it is freely movable. Its length varies considerably, but in all the cases that I have operated on it was long, at least three or four inches, and thus its mobility and length permit of its being doubled over or displaced in such a way as to cause it to kink, or to lead to obstruction of the nutrient artery. In furtherance of this idea, the fact may be mentioned that one usually finds the appendix on operation doubled on itself, any perforation present being located either at the convexity of the kink, or at the tip, the spot one would expect to atrophy if the nutrient vessel were obstructed.

In all probability the direction taken by the appendix is an important etiological factor, since if it is directed downwards and backwards, it is much more likely that faecal material will find its way into it; certainly the impression received by me from the operations that I have undertaken and seen, is that the appendix is usually found behind the caecum and directed more or less downwards. The *Bacillus coli* is a constant inhabitant of this cul-de-sac, and should the communication with the intestine become obstructed, it is easy to see that another potent predisposing element is added to the picture.

Turning now to pathological anatomy, it is essential to realise that the trouble is from the first of an infective nature, due to the migration from the intestine of organisms, prominent amongst which is the *Bac. coli communis*. Not unfrequently ordinary streptococci are also present in

* Sent by the Author for publication in the Record.

the early stages, but it has been shown that the pus usually enters the upper part of the appendix, and consequently it is in this part that the pus enters the appendix, and their progress is usually arrested by the penetrating odour of the pus. The germs attack the walls of the appendix, and find their way into the abundant lymphoid tissue present in the submucous tissue; there they develop, and generally subacute suppurative is the result, the pus becoming yellow from many purulent foci. In other cases ulceration or gangrene rather than suppuration occurs, and then the peritoneum is quickly affected, and according to the rapidity and violence of the attack, a localized or diffuse peritonitis results. It is on the nature of the peritoneal complication that the prognosis of any particular attack chiefly turns, and from this point of view three main divisions of acute appendicitis may be described: (1) that associated with merely a plastic peritonitis, leading to adhesions, but not resulting in purulent infection; (2) that in which a localized abscess develops, which is always primarily intra-peritoneal, and limited by a zone of protective adhesions; and (3) that accompanied by an acute diffuse peritonitis. In both of the latter divisions the appendix is likely to be in a condition of ulceration, perforation, or gangrene.

It must not be imagined, however, that the only dangers of this affection are due to the peritoneal trouble. A very important and serious element exists in the fact that the venous system is occasionally infected, and that pyæmia may result therefrom. The venules in the meso-appendix become thrombosed, either by direct extension from the inflammatory focus in the walls or by the kinking or torsion of the process, the thrombus being secondarily infected from the bowel. Emboli are detached from this and carried up to the subdivisions of the portal vein in the liver, leading to portal vein pyæmia or pylephlebitis, as evidenced by high fever with recurrent rigors and distinct hepatic tenderness; true general pyæmia may subsequently develop. Another venous complication that may arise is thrombosis in the iliac veins, leading to the so-called "white leg"; this is probably due to pressure of an inflammatory mass upon the venous trunks in the iliac fossa. In addition to all these phenomena it must not be forgotten that toxic symptoms of a marked character manifest themselves, and that a considerable depreciation of the general powers quickly ensues from this cause, and may render an operation fatal which, undertaken under more favourable auspices, would have been successful. Some months back I was called in to operate on a young lady who had been allowed to remain in a febrile state for six weeks with a large abscess in the iliac fossa; at the time of operation there were additional symptoms of peritoneal invasion, but although the proceeding was a simple one, and the abscess easily found and opened, yet the shock was sufficient to produce a fatal issue from cardiac failure. At any time during the preceding six weeks an operation would have been justifiable and probably successful, but the continuance of general symptoms from continued toxic poisoning sufficed to turn the balance in the wrong direction.

Into the symptomatology of appendicitis space forbids me to enter at all fully, but a few points suggested by some of my cases must be alluded to. The general

features of an attack of acute appendicitis, and the usual clinical picture is very characteristic. The onset of pain referred to the right iliac fossa, fever, vomiting, and constipation, are the cardinal symptoms. On careful examination patients usually point to their pain to what is now known as McBurney's point, i. e. a point $1\frac{1}{2}$ inches inwards from the anterior superior iliac spine along a line drawn from it to the umbilicus, and corresponding with fair accuracy to the attachment or base of the appendix. The pain is increased on any movements of the abdominal parietes, and when the right leg is usually kept well flexed, and the overlying muscles rigidly contracted. The fever necessarily varies with the character of the attack, rarely running above 101° in the mild cases; in an acute localized abscess the temperature at first is often very high, but it is not at all unusual to see it drop in a few days, probably as a result of toxæmia; in patients with diffuse peritonitis there is frequently but little pyrexia, the temperature not rising much above 101° . On palpation one frequently finds a mass occupying the right iliac fossa, which consists of coils of intestine matted together over and around the inflamed appendix. It is sometimes tympanitic, but may be quite dull. The outline of this mass is likely to be blurred and indistinct if there is much concurrent distension of the small intestine, and in cases where the appendix lies behind the caecum there may be neither dullness nor tumour to be detected.

The formation of an abscess is not necessarily associated with any increase either of the local or of the general disturbance, and one must never be tempted to wait for fluctuation before determining as to the necessity of an operation. Thus in one of the cases I have already alluded to, the patient was taken ill on the Friday night; the temperature was high, and there was continuous vomiting and constipation. He was carefully treated, and when I saw him on the following Wednesday the temperature had fallen to the normal, the vomiting had ceased, and a natural motion had been passed. The abdomen was tense and tympanitic, but not particularly tender; the only symptom that caused much trouble was hiccough. Naturally one concluded that the stress of the inflammatory mischief was over, and that the distension would be relieved by evacuation of the bowels. This was undertaken by means of enemata and calomel, and the hiccough ceased, although the distension continued, and on Saturday, when I saw him again, was as marked as ever. Operation was then decided on, and on raising the caecum from its bed an abscess of some size was found, connected with a kinked and perforated appendix.

The direction taken by the pus necessarily varies considerably with the position of the appendix; if it is situated on the anterior aspect of the caecum, the abscess tends to point through the anterior abdominal wall, causing it to become red and edematous. If, however, the appendix is located behind the caecum, the pus may remain limited to one of the pouches behind that viscus, or if allowed to collect in any quantity may burrow in various directions. Thus it may perforate the posterior layer of peritoneal mesentery, and get into the retro-peritoneal space. Other causes lead to the surface just above the iliac fossa, or travelling up behind the peritoneum to point below the ribs, perhaps on the

the appendix may be seen, and the connective tissue bands above the ileum, constituting a sub-peritoneal abscess. Whether one of importance must be recognized, viz. that a retro-caecal abscess may burrow downwards behind the rectum and form a large fistula, or collection of pus, particularly when the appendix is directed upwards and downwards, as is so commonly the case. Under these circumstances pain and tenderness can be detected on rectal examination, and this means of investigation should never be neglected. In one of my patients there was no sign of local tenderness on examination of the iliac fossa, but distinct pain was elicited on making a high rectal examination, and on operation an abscess was found behind the caecum, and tending to spread downwards.

Turning now to the subject of treatment, one is at once confronted with the much vexed question as to the circumstances under which operation ought to be undertaken. On the one hand there is the extreme American school which teaches that every case should be treated actively by the surgeon within twenty-four hours of the onset, and on the other may be ranged the vast proportion of British practitioners who still persist in the belief that operation should only be performed late in the course of the case, and when definite suppuration or peritonitis is present. There is much to be said on each side, and facts and figures could be quoted upholding the ideas of each school of thought. Figures are, however, proverbially untrustworthy, and readily twisted to prove anything. The subject needs to be approached without bias, and exaggerations on each side must be avoided. Two or three introductory facts must ever be kept in mind:

1. There is a considerable proportion of cases which get perfectly well under ordinary medical treatment. We grant that point, say the advocates of operation, but at what risk! and how prone these cases are to relapse!

2. The statistics of cases admitted into surgical wards for operation have been very unsatisfactory, the mortality being terribly high. This, again, must be admitted, but the explanation is not far to seek. The high mortality of operations for appendicitis is due to surgical assistance being sought too late; either the general peritoneal cavity has been infected before operation, or the patient is so profoundly poisoned or so much exhausted by the preceding inflammatory phenomena that the shock of the operation is sufficient to destroy his life.

3. When acute general peritonitis exists there can be no question as to the method of procedure which holds out the only hope of cure, viz. operation, but unfortunately the prognosis here is only too unsatisfactory; very few of the patients attacked in this way will be saved.

4. Another important point to remember is that no one can exactly anticipate the course which will be taken by any particular attack. All the different types start very much alike, and the uncertainty that enshrouds the prognosis is one of the most important arguments in favour of early and active interference; in other words, the surgeon ought to operate whilst the disease is limited and has not got out of hand.

Turning, therefore, on the one side to the mild cases that may require medical treatment, and on the other to the inflammatory cases of acute peritonitis which are cer-

tainly as fatal, apart from their need of energetic surgery, and admitting entirely any combination of chronic overlapping appendicitis, there still remains a large group of localized cases between the two extremes, characterized by well-marked local and general phenomena, the outcome of which is always a matter of anxiety. Such are these patients where the temperature rises high, where the local tenderness is excessive, where vomiting and constipation are urgent, and perhaps a distinct swelling occurs in the iliac fossa, that surgery is so valuable at an early stage.

The considerations that have led me to take up a definite position in favour of early operation are very numerous, and some of them have been already alluded to.

1. One can never be certain that the infection of the peritoneal cavity will be limited to the neighbourhood of the appendix. A zone of strong adhesions may develop, but the practitioner can never be quite positive as to this point; and even should they form, it is always on the cards that they are incapable of checking the onward progress of the infection. Early operation and removal of the appendix will in careful hands prevent any such catastrophe.

2. If the disease is allowed to run on, the patient's general condition rapidly depreciates as a result of toxæmia; cardiac failure is a consequence of late operation, and is probably due to the influence of the toxins on the heart muscle. The shock produced by an early operation is comparatively slight, and the fact that several American surgeons have been able to publish lists of hundreds of cases operated on early with a mortality well below 5 per cent, speaks eloquently as to the value of such a proceeding.

3. The removal of the appendix is always a desirable step in the operation, but when such is delayed until a well-marked abscess has formed, removal often becomes impossible. The appendix is frequently embedded in the abscess walls, and even if found its walls are rotten and friable, so that in some cases all one can do is to tear it away, or perhaps ligature its base, at the same time expressing a pious hope that a fecal fistula may not follow. Moreover, it must not be imagined that an inflammatory attack, sufficiently intense to cause an abscess, is always capable of determining occlusion of the appendix and a consequent immunity from the risks of recurrence. It has been shown by STIMSON and others that relapse under these circumstances can not only occur, but that the appendix may be found free from adhesions; and certainly in one of my own cases this condition was present. I had opened an acute appendix abscess in a woman, and was unable to find and remove the process; the wound was allowed to heal by granulation, and a year or two later I had to operate again for a ventral hernia which had developed. The peritoneum was opened, and I took the opportunity of investigating the state of affairs in the iliac fossa; the appendix was then found free from adhesions, but thickened, and with its intestinal end stenosed; at the apex was a bulbous dilated portion containing offensive mucoid secretion, which was certain sooner or later to have lighted up another attack.

Early operation enables one to remove the appendix in almost all cases. The adhesions present are slight, and are easily separated without causing much bleeding; the meeting of the parts together is so limited that one can

readily reach the focus of the mischief; the appendix itself is usually firm enough to serve as a ligature; it satisfactorily, and therefore a second incision is less likely to form; the operation need not last many minutes, and hæmorrhage is minimised; the incision can often be much smaller, and the wound, even if it cannot be safely closed entirely, need not be left widely open for the removal of faecal stuffing, and therefore the risks of the subsequent development of a ventral hernia are much less.

Agut, relapses are entirely prevented, and the necessary limitation of diet and exercise, which is such an important measure after the cure of a bad attack of appendicitis by medical means alone, is not required. The patient is left quietly in bed for three weeks or more, according to circumstances, and at the end of his convalescence returns to his ordinary avocations without any prolonged period of medical supervision.

It must be clearly understood, however, that what is meant here by early operation is a proceeding which is more nearly akin to American ideas than to those usually held in this country. TREVER, whose reputation in this branch of abdominal surgery is well founded, states that in his opinion operation, though justifiable on the fifth day, is rarely needed during the first week, and that the essential feature in this treatment consists in "a free incision down to the inflamed area as soon as there is evidence that suppuration has taken place" (CLIFFORD ALLSOPP'S 'System of Medicine'). With this opinion I cannot agree. The facts brought forward by me above are to my mind quite sufficient to justify the surgeon in *anticipating suppuration*, and I cannot but believe that a more frequent recourse to operative proceedings would diminish the death-rate of this disease. Certainly one has often regretted delay in treatment; I have never known or heard of a case where one could be blamed for operating too soon. Hence the rule of treatment which I would submit as justifiable is—*That if under suitable medical measures the condition is not at a standstill or actually improving at the end of forty-eight hours, operation should be undertaken.* Of course there are exceptions to every rule, and this must not be taken as a rigid, inflexible dogma; exceptions to it will occur, and must always be allowed for. The surgeon under these circumstances will not wait for œdema or congestion of the abdominal wall, or for the existence of fluctuation. The patient when first seen is put to bed and kept absolutely quiet. If constipation has been previously well marked, an enema should be administered to clear away irritating material from the lower bowel. The diet is restricted to fluids, and possibly if vomiting is very urgent rectal alimentation may be needed. Hot fomentations should be applied to the lower part of the abdomen, and a little morphia ordered. This treatment should continue for forty-eight hours, unless signs of general peritonitis are already present; if the symptoms persist or are becoming aggravated at that time, operation should be resorted to without hesitation. As particularly bad signs may be mentioned (i) a rising temperature, (ii) a falling temperature with increased rapidity of the pulse, indicating a steadily progressive toxæmia, and (iii) the existence of hiccough or focal vomiting.

As to the details of the operation, space forbids me to

give more than the briefest outline. The incision is an oblique one, varying in length to the extent of the abdominal oblique, and located nearly parallel to Pott's line, highest and above its outer third; it should pass through McBurney's spot. The abdominal muscles are then divided, and the peritoneum opened; the greatest care should be taken in incising this latter structure, as the cæcum may be intimately adherent to its under surface, and then runs considerable risk of being injured. In some cases the appendix will at once present, but not uncommonly it has to be carefully looked for. Possibly the omentum is adherent across the face of the cæcum, and must first be detached or divided. The cæcum is then gently lifted from its bed, and the appendix is very commonly found behind it. Some assistance may be gained by remembering the fact that the three bands of longitudinal muscle fibres converge to form the outer muscular coat of the appendix. When once found the process is freed from its connections, the meso-appendix being, if need be, ligatured and divided. Sometimes all one can do is to tie the base of the appendix with a silk ligature; but if practicable, a definite amputation should be undertaken. The serous and muscular coats are divided by a circular incision about one centimetre from the cæcum, and turned back like a cuff from the central tube of mucous membrane. This is then ligatured, divided, and purified by touching with pure carbolic acid; the sero-muscular cuff is then drawn forwards again and sutured securely over the divided mucous membrane.

The question of drainage cannot be treated dogmatically; the character of one's practice must depend upon the case. If pus has been present, it is probably wise to insert a large tube, and stuff strips of gauze into the interstices of the wound around it; but if suppuration has not occurred, the tube may be dispensed with, and merely a gauze packing utilized, the amount of which is dependent on the condition of the appendix and the probable extent of the bacterial invasion. The closure of the wound will also vary considerably; the larger the amount of stuffing, the fewer the stitches which are inserted.

—o—

BRIEF NOTES ON THE PRACTICAL ANATOMY OF THE SHOULDER.*

By THOMAS H. MANLEY, M.D.

Professor of Surgery at the New York School of Clinical Medicine.

THE writer has been led to undertake a brief study on the above subject, chiefly for the reason that the anatomy of those parts, as set forth in most text books and works on surgery, is in many essentials misleading, unsatisfactory and indefinite; nor can one find in any published work a full and accurate description of the structures within the shoulder-girdle, or those structures contiguous to, or in juxtaposition with, it.

At the present time, when the remarkable advances in the science and art of surgery have permitted the isolation of every structure in the complex mechanism of the shoulder within the domain of radical surgery, in order to take proper advantage of this, something more than a general knowledge is requisite, where precision and accuracy are required. Until the literature upon

* Reproduced from the *University Medical Magazine* by the author's request.

the shoulder, the scapula, clavicle, humerus, and radius, are all exposed to the same danger. But the shoulder is the most exposed, and the danger of infection is possible, and the danger of osteomyelitis has been frequently observed. The shoulder is one of those exposed regions of the trunk, to come within the range of exposure, and for the relief or cure of many lesions of the shoulder, which in the near past were regarded as hopelessly incurable.

Mode of acquiring Special or Practical Anatomy.—We require a knowledge of practical anatomy of a region in various ways—

(1) By the aid of treatises on anatomy. This affords us but a relative and indefinite knowledge, because many illustrations are defective, because different authors give different names to the same structure, and finally, because deviations in development are found in nearly every subject.

(2) Dissection on the cadaver—dead anatomy—is the most valuable of all methods in the study of anatomy.

(3) The study of the living anatomy is something too much neglected, but of great value. In muscular subjects, devoid of much fat, muscular movements at the shoulder may be studied with advantage.

(4) A study of comparative anatomy, combined with dissection of the lower animals. No one can pretend to a general knowledge of anatomy who has not given some attention to this side of the subject.

(5) By vivisection only can we learn physiological anatomy. This is of inestimable value, if for no other purpose than acquainting ourselves with the mechanism of the parts in motion. Surgical operations are a species of vivisection, and hence, the oftener the surgeon operates the better practical anatomist he becomes.

All of the above is germane to our subject, for, everything else considered, the more thorough anatomist the surgeon is the more valuable his opinion and successful his treatment of shoulder or other lesions will be.

Physiological Anatomy of the Shoulder.—The shoulders in man hang suspended from the spine. They afford shelter and protection to the viscera of the upper areas of the thorax; defend the cranium, spine, and chest against injury, and are concerned in prehension.

A striking peculiarity here is the triple arrangement, the vicarious function of various structures, and atypical construction,—three special and definite characteristics.

Thus, there are three bones in the skeleton of the shoulder, three joints, three large superficial muscles, each with three separate heads or origins for the superficial layer; there are three large nerve-cords in the brachial plexus, below the clavicle.

The central segment of the deltoid muscle is rich in fibrous tissue, as is the brachial plexus, and hence both serve as auxiliary ligaments.

All the joints are singularly atypical; the costo-scapular possessing neither synovial membrane nor ligaments; the humero-scapular, being without independent ligamentation; and the clavicular scapular, having no muscular connection.

The scapula is as placed and so constructed as to afford great resistance to violence in the upper part of

the trunk, a certain amount of structure, it is well calculated to resist the impact of great violence and defend it with comparative impunity.

The method and complex mechanism of the shoulder is a long voluntary provision against various injuries.

When time or working periods, in an instant the shoulder on one side, or both, is instantly fixed in such an attitude as to best divert the impending blow from the body. It is, therefore, a powerful movable shield.

The Shoulder Skeleton.—The scapula or shoulder blade serves for the insertion of those muscles which move it and secures a fixed fulcrum for the leverage of the humerus. Its neck and apophyses are quite extensively concerned in providing lodgement for the head of the humerus and giving origin to those muscles which act on it.

The clavicle or collar-bone presses the scapula away from the central plane of the body, and contributes to the square outline of the shoulder. It therefore serves the purpose of a horizontal prop, but in no manner contributes to strength or motion, as it is wanting in those quadrupeds of the greatest power and agility, and, moreover, it has been lately demonstrated that its extension but slightly, if in any degree, impairs shoulder-action.

The humerus, by its greater tuberosity or outer head, imparts a fullness and rotundity, continuous with the sloping ridge of the acromion process. The large humeral head, the inner or articular, has but a narrow, nearly flat surface to move on; yet, its indirect osseous cavity is spacious, and hence the head of this bone is more deeply lodged than that of any other shaft in the body.

The articular head of the humerus, in the erect attitude of the body, is inclined inward and forward, and has a very wide range of action.

Three points of great practical importance should be carefully noted in the above,—viz., that there is no shoulder-joint, but shoulder-joints; that there are two heads at the scapular extremity of the humerus, the external the greater tuberosity, being susceptible to palpation, the true articular head being always deeply concealed; and that the clavicle is not essential to full functional strength of the shoulder.

The Nerves of the Shoulder.—The principle nerve-supply of the shoulder is from the cervical and brachial plexus. The brachial plexus is of great surgical interest, not only from the aspect of its divisions in their relations to important structures, but because of the contributory support which they provide to the inner aspect of the shoulder. The three large nerve-cords in the third stage of this plexus have a considerable proportion of fibrous tissue in their sheaths and their interfascicular septa; they are of remarkable tensile strength, and must be regarded as important auxiliary ligaments in supporting the anterior segment of the shoulder. THAKKUR, based on experiment, that each cord was capable of maintaining about thirty-eight kilogrammes weight, about 80 pounds.

Synovial Pouches or Bursa.—Extending from the summit of the glenoid fossa outward to the upper ridge of the anatomical neck of the humerus is a broad, deep synovial sac, usually designated the "subacromion bursa." It is evidently formed by a reduplication of the superior wall of the capsule, although its upper radiation is freely

the head of the humerus is rotated outward and the tendon of the subscapularis is put on a strain; but when the head is rotated inward, it is so mobile and so mobile that it interposes itself between the inferior acromioid process and the greater humeral tuberosity and hence it serves an important physiological purpose.

Dislocation of the humerus is apparently to diminish the friction of movement when the arm encounters resistance and the rotating head of the humerus is forced forward and backward.

TORPOR INTESTINORUM - (CONSTIPATION) ITS CAUSES AND TREATMENT IN INDIA.

By SURGEON-MAJOR R. E. WEAFFER, Bengal Medical Service, (Retired), Dacca Division.

CONSTIPATION, or costiveness, is that condition of the bowels in which the stools are less frequent and less in amount than in the healthy state. This is among the most common of all minor ailments for which the advice of the doctor is sought. A faulty diet and sedentary habits are the main causes of its production. Constipation may be either occasional or habitual. In certain persons there exists a marked constitutional tendency to constipation of the bowels, and in such, while the condition, with its attendant discomfort, may be partially relieved, it not unfrequently happens that it cannot be altogether overcome. The direct or immediate causes of constipation most frequent in their operation, are failure in the contractile power of the muscular coat of the bowels, or perhaps more strictly speaking, a want of nervous power in the spinal cord (a power which governs the muscular coat of the bowels), and an alteration in the quality or diminution in the amount of the intestinal fluids which serve as saline stimulants; and these three are the chief in importance. In old age the nervous system of the body has become weakened and as a consequence, costiveness results. Let it be said here that there is a very considerable variety exists in regard to the interval at which passing from the bowels occurs in different individuals. While, undoubtedly, most persons in health have one evacuation in the course of twenty-four hours, there are not a few whose bowels move only once in three or four days, and there are others whose bowels move several times in the course of twenty-four hours. It is not, however, the frequency of the evacuations which is the chief consideration, but the nature of the stools. In a healthy state the stools are soft and of a moderate amount, and are passed without any effort or pain. In constipation the stools are hard and of a small amount, and are passed with great effort and pain. The treatment of constipation is to be directed to the removal of the causes which produce it. If the cause is a faulty diet, the diet should be corrected. If the cause is a sedentary habit, the patient should be encouraged to take more exercise. If the cause is a constitutional tendency to constipation, the patient should be treated with laxatives. The most common laxative is castor oil, which is given in the form of a draught. Other laxatives which are sometimes given are senna, rhubarb, and calomel. The treatment of constipation should be continued until the bowels are in a healthy state.

...the liver is in any degree suspended, and healthy bile does not reach the bowels in due amount, there exists a fruitful source of constipation; hence the absence of the biliary color from the stools, which is so often noticed in those who suffer from constipation, and especially in children. The sufferer from opitiveness is subject to various uneasy and oftentimes distressing sensations, both in the bowels themselves and at a distance from them, headache, lowness of spirits, derangement of the stomach, failure of appetite, are among the most common and ordinary of its effects. Sometimes we observe thoracic symptoms emanating from such a source, such as tightness across the chest, difficulty of breathing, and a hard, dry cough. These effects of constipation are probably referable to distension of the great arch of the colon, and consequent impediment to the free motions of the diaphragm. At other times the mucous membrane of the colon and rectum obdurely suffer, and the result is piles. It is well to observe that some individuals suffering from torpor of the large intestine state their bowels are regular, simply because they go to the closet every day, when in reality they suffer from habitual constipation. As they only pass small lumps of hard feces, occasionally also, there may be straining, and the hard lumps may be passed with a fluid watery discharge, the result of the irritation they cause; this is often mistaken for diarrhoea, instead of being recognized as the effect of constipation. A very common condition from which the pregnant female suffers is a constipated state of the bowels. It is a very distressing affection, and is due partly to the mechanical pressure which the enlarged womb exerts upon the bowels, and partly to "defective innervation of the bowels resulting from the altered state of the blood."

Stool action may be greatly retarded by an over-accumulation of the bowels, and as the danger both to mother and child increases with delay, the risks become greater. The pregnant will be in a state of least depression if she takes that action will is all probability to be taken, and after, when, along with attention to the bowels, the patient has been the subject of the bowels, and the bowels are not properly innervated. REPORT OF A CASE OF

ADHESIVE RETROVERTED
UTERUS, LAPAROTOMY, REMOVAL OF CYST,
RESECTION OF UTERUS BY FIXATION TO
ABDOMINAL WALL: RECOVERY

By EDWARD H. WALLACE, M.D., F.R.C.S.I.,
Fellow of the Obstetrical Society of London,
Member, British Medical Association,
Formerly Resident Surgeon, Eden Hospital
for Women and Children,
Calcutta, etc.,

P.B., an Armenian lady, born 1874, of good physique, menstruated at 12 years of age, regular as to time, quantity and quality, enjoyed perfect health during her childhood and womanhood, was married at 15 years, had her first child 2 years later, puerperium normal, lost her husband two years ago, subsequent health good up to March 1898

Her menses before this date were regular and free from pains occurring once in 28 days. Since March the flux has appeared every 20 days and has been attended with much pain, chiefly in the left iliac fossa, which is most severe 2 days before and for 2 days during the flow. This condition of things has continued for the past 6 months, the symptoms becoming more aggravated each month. Constipation was a constant trouble and was very distressing during the catamenial epoch.

The patient first consulted the Obstetric Physician of the Calcutta Eden Hospital in March last and was told she had inflammation and retroversion of the uterus. She was placed under treatment for 5 months and was then informed that she was suffering from an abdominal tumor which must be cut out. She first consulted me on the 14th of August and after hearing her case and learning that she had come to me for a definite opinion as to whether there was a tumor in her abdomen which ought to be operated on or not, I examined her carefully, and told her that there was a tumor and that it should be operated on without delay. I strongly advised her to go back to the physician of the Eden Hospital, but she flatly refused to enter that institution for an abdominal operation, and begged of me to arrange for the same in some healthy part of the city. Dr. FELDSTEIN who was present at this consultation and heard the patient's emphatic objection to undergoing an operation in the Eden Hospital, very kindly agreed to allow her to be treated in his house, and accordingly the arrangements for the operation were made.

The physical examination of the 14th and 18th August presented the following features:

There was distinct bulging of the left iliac region, with tenderness and pain on palpation. A lump as big as a small orange could be felt, and on vaginal examination this tumor was found located in the left broad ligament. The uterus was retroverted and firmly fixed, the lump being quite 2½ inches away from the clearly defined contour of the uterus, which though bowed down by adhesions had a clear outline and was not at all enlarged nor tender to touch. The right iliac fossa was clear, the cervix was not displaced upwards. It was clear that we had to deal with a tumor of the broad ligament, which must be removed by laparotomy, and as the patient was distressed by a very intense pain, a laparotomy

was performed. The patient seemed to be in good health and the only serious symptoms, an abdominal operation, was the increasing abdominal distension, consequent severe pain and the presence of a general feeling of suffering and probable further pain, constipation. The risks of the operation were fully explained to the patient and her friends, but she expressed a determined wish to be relieved by such a measure.

Accordingly on the 18th August 1898 the patient was put to bed and kept on low diet for three days.

On the 21st August at 8 A.M., after the bowels had been well cleared with an enema of warm soap water and after the room had been thoroughly disinfected with sulphur and the patient carefully prepared under aseptic precautions, she was operated on by Dr. Z. FELDSTEIN, and with the assistance of Dr. WILLIAM COULTER, I opened the abdomen in the middle line, slit up the peritoneum, and passing my hand down into the left side of the pelvis, picked up the tumor, which was free from adhesions and was found to consist of a very much distended condition of the fimbriated extremity of the left Fallopian tube. The cyst wall was extremely attenuated and perfectly translucent, the tube was also much dilated and very tortuous, having the appearance of a twisted cord almost as thick as one's little finger. The left ovary was perfectly healthy, so also was its fellow. The fundus of the uterus was fixed in the sacral fossa and must have been a source of very severe mechanical obstruction to defecation. The fundus uteri was carefully freed from its adhesions and this gave easier access to manipulation of the diseased Fallopian tube. Fearfully dissected the cyst and tube away from their attachments, leaving the healthy left ovary intact. Having ligated the pedicle of the mass, it was removed, with the fortunate occurrence of not rupturing the cyst nor of allowing its pathogenic contents to escape into the peritoneal cavity. All bleeding points were carefully secured and the abdomen freely irrigated with pure boiled water. The uterus was not superficially transfixed by a curved needle armed with strong silk gut and the stitch was made to pass through the abdominal wall at the lower part of the wound. The uterus thus underwent abdominal fixation, and when the parts were thoroughly healed, it was found firmly adherent in its new position. Three layers of stitches were used to close the wound, the first of sterilized silk gut through the peritoneum, the second of the same material through the muscles, and the third of silver wire through the skin. The wound was closed completely and no drainage tube was used. Boiled compresses of sterilized unmedicated gauze and cotton were used as dressings, a bandage being covering them. Similar sterilized dressings were used subsequently. The patient rallied well after the operation, her temperature rose to 100°F. in the evening but fell to normal the next day and remained so. She was fed by rectal nutrient enemata for 48 hours, and during this time was allowed small quantities of ice to suck. On the 3rd day she received milk and gruels and cold water. On the 15th day she was given light solid food. There was a natural alvine evacuation the day following the operation and the rectum was daily emptied by an injection of glycerine. The dressings were changed on the 4th day and then every alternate day. The wound healed by first intention.

tention and the stitches were removed on the 14th day. On the 20th day the dressings were discontinued and an elastic abdominal binder was worn from this date. The patient left her bed on the 21st day and on the 30th day after the operation she was able to take a comfortable and enjoyable drive in a victoria. I have seen her frequently since the operation, and it is satisfactory to note that her menstruation has come with perfect regularity and with absolute freedom from pain. I saw her last on the 4th of November, and she left Calcutta that evening on a trip to Singapore, in perfect health.

I take this opportunity to express my best thanks to Dr. COOPER for his able assistance at the operation, as also to Dr. FALSBURG for his skilful management of the chloroform, and to Mrs. DEERHOLTS for her help during the operation. I desire also to mention with appreciation the efficient services of Nurses WOOL and CROSBIE in the after management of the case.

:O:

SEVERE PELVIC SUPPURATIVE CELLULITIS. RECOVERY.

By Assistant Surgeon J. C. GILLMAN, L. R. A. Lond.

Offg. Civil Medical Officer, Puri District.

MARNA, a Hindoo woman set 24, about four months pregnant, came under my treatment on the 16th August. It appeared that the day before she noticed a mucous discharge tinged with blood escaping from the vagina. On examination the os was found somewhat dilated and abortion threatening and as there were no pains, Tinct. Opii m. xv, every 3 hours was given, combined with absolute rest to avert the accident, but without success, for on the following night labour pains set in, and on the morning of the 17th she was delivered of a dead foetus, the liquor amni had the appearance of very thin pus, the placenta being apparently intact.

Matters went well with the patient until the night of the 20th when the temperature suddenly rose to 104°F with out previous shivering or pains of any kind. Next morning there was little or no subsidence of the fever, bowels constive, furred tongue, pulse quickened and small, with tenderness over the whole abdomen, especially the hypogastric region, attention was drawn to the genital organs, the lochia was found to be foul and very offensive. Antiseptic douching of the uterus and vagina every 3 hours was ordered, large, moist, warm poultices smeared with Belladonna applied to the abdomen and soda salicylas gr x, Tr. Opi m. x, aqua ʒi was given every 4 hours, with absolute rest. The temperature ranged between 101° and 103.8°F. for the next three days, when an improvement was noticed, the morning temperature fell to 100.4°F. and the evening to 101.4°F. tongue moist and clean, abdominal pain and tenderness quite gone and the discharge per vaginam lessened and free from smell. Quinine Sulph was now pushed and given in x gr. doses t. d. s. with marked benefit, for on the 26th, the general condition of the patient was decidedly better, the highest temperature being 99.6°F. which during the day fell to normal, and continued so till the 31st, when she insisted on getting about as she said she felt quite well. On the night of the 4th Sept. she was suddenly seized with severe abdominal

pains. When seen on the following morning, her condition though not serious, was bad. The temperature was 101.8°F. skin hot and dry, tongue covered with a thick white fur, no headache, much thirst, indifferent appetite, bowels not moved for two days, calm features, pulse quick and frequent, 120 per minute. The abdomen was tympanitic, distended and very tender to the touch, thoracic respiration 30 per minute, relief was obtained by lying on either side with the knees drawn up. The same line of treatment was adopted as before, i.e. absolute rest. Belladonna and warm poultices to abdomen. Quinine gr. x Bile dis. Ram ʒss 4 times a day with 2 seers of milk during the 24 hours. In the evening the symptoms were more aggravated and the temperature rose to 104.4°F. Next day the temperature did not fall below 103°F. She passed a bad night, had no sleep, in spite of a grain and a half of opium, was fidgety and rejected her food. For the next few days the temperature varied from 102° to 103.8°F. with gradual abatement of the general symptoms, the abdominal pain decreased and on the 9th was found to be localized to the hypogastric and right iliac regions, and on the 11th a rounded painful swelling could be distinctly felt above the pelvic brim. On vaginal examination the uterus was found to be fixed and the tumour adherent to it. Poultices and treatment continued. Irritation of the bowels now set in with the expulsion of a quantity of mucus, probably due to adhesions between the rectum and the tumour. Castor oil emulsion was given to clear the intestinal tract and relieve any tendency to constipation. The mucus ceased on the 16th and with it the general condition of the patient took a turn for the better, the morning temperature came down to normal and the evening temperature below 100°F, the pain over pelvic swelling diminished which was greatly facilitated by the repeated applications of blisters. On the 19th the abscess burst and discharged its contents into the rectum, a large quantity of pus was found in the stools, from this day forward the temperature remained normal and the pelvic swelling disappeared though slight tenderness on pressure was still present. A steady progress towards recovery ensued, pus was passed for several days by the bowels, but in gradually diminishing quantities which completely disappeared. The pelvic tenderness lingered for a longer time, but by the 7th of October she had completely recovered. The rectum was frequently washed out with a 1 to 50 carbolic solution and during convalescence Tinct. Nux Vomica m. xiii, Quinine Sulph. gr. ii, Inf Quassia ʒi t. d. s. was given with nourishing diet.

:O:

CIRCUMSCRIBED TRAUMATIC ANEURISM OF THE PALM.

By ARNOLD UADY, F.R.C.S. Eng.

Member of the Clinical Society of London, etc.

THIS rare condition presented itself in a European lady aged 33. About March 10th 1898, while resting her right hand on a wineglass the latter gave way and broke, cutting the palm of the hand, the wound bleeding profusely. The wound was dressed and healed in five days. Four days later the scar was noticed to be tender when holding the reins while driving. Gradually at the site of the original wound a small pulsating swelling appeared, which,

Palmar aneurism. This swelling was only painful when the hand was used for grasping objects, but was not painful to pressure.

I saw the case for the first time on April 17th 1898, and then there was a rounded pulsating swelling in the right palm, the size of a nutmeg, lying between the roots of the middle and ring fingers on a level with the heads of the metacarpal bones. Pulsation ceased on compression of the radial and ulnar arteries.

On April 19th under chloroform and assisted by Dr. GARTH of this city, I tied the radial and ulnar arteries at the wrist. The wound was dressed antiseptically and the hand and forearm put on a straight splint.

On 21st April the tumour was quite hard, without pulsation and the circulation in the fingers was perfect.

On 26th April the wound was healed and the tumour had perceptibly shrunk. The splint was worn until 8th May and then the hand was only carried in a sling.

By 3rd June the tumour had shrunk to the size of a small pea and the hand was in constant use.

I have recorded this case on account of the rarity of palmar aneurism, whether spontaneous or traumatic. I was prepared to tie the brachial artery if ligature of the radial and ulnar arteries had failed, which event might have occurred owing to the free anastomosis existing through the interosseous artery and the palmar arches. The patient was desirous of trying the less severe measure first and the operation was a complete success.

CRANIOTOMY COMBINED WITH PODALIC VERSION.

By R. SRINIVASA PILLAY, C.M.S.

Municipal Hospital, Kurnool.

On the evening of 3rd October 1898 at 2 P.M. I was called to see a Mahomedan woman in labor.

History.—Primipara, full term. Pains commenced at 3 A.M. on 3rd, membranes ruptured at 7 A.M. followed by expulsion of one of the lower extremities. A native "Dhai" had been sent for at 8 o'clock, who is reported to have done nothing. The hospital nurse was summoned at 12 noon, she attempted to perform "turning" but failed in the attempt.

The patient being a Goshia woman would not admit a man into the room till she was under the effects of chloroform. She was about 18 years, well nourished and in a good state of health. On examination I found the child dead, neck constricted at the pelvic outlet, vagina hot and moist and the umbilical cord lying over the head. The symphysis menti was firmly fixed against the symphysis pubes and the head was lying in the right oblique diameter of the pelvis, the uterus being firmly contracted on the head. The operation of craniotomy was thought advisable and was resorted to.

The cranium was perforated behind the right ear. One blade of the cephalotribe was introduced into the cranial cavity, the contents escaping after a few minutes, delivery was effected with a sudden rush, the placenta was expelled at the usual time.

4th October 1898.—Complaints of slight pain over the uterus, bowels moved, urine voided, nourishment detained, sleep fairly well.

11th October 1898.—Bowels constipated, lochia discharges normal and healthy, doing well. She was discharged on the 15th perfectly well.

Indian Medical Record.

16th November 1898.

THE COLONISATION OF THE TROPICS BY WHITE MEN.

THE question of the possibility of white men becoming acclimatised, and perpetuating their race without degeneration, in the tropics, is far too attractive both to the theorist and to the practical man, to be left long in abeyance.

The carefully weighed verdict of our immediate predecessors that such acclimatisation is impossible, has lately been called in question by a few medical men whose bias towards theoretical assumptions, appears to us, to have outrun their practical knowledge; and the importance of the discussion has been much enhanced by a series of letters which the distinguished author of "Social Evolution" BENJAMIN KIDD, has contributed to *The Times*.

When a man of KIDD's calibre enters upon a topic of this kind we may feel certain that it will be handled in a thoughtful and masterly manner, and we are not disappointed. In his three letters entitled "the Control of the Tropics," he gives us a luminous survey of the matter from several points of view, and in his conclusion that it would be a "blunder of the first magnitude" to attempt to colonize the tropics in the same fashion as the temperate parts of America, Australia and Africa have been colonised, we see every reason to agree.

The *British Medical Journal*, however, quarrels with Mr. KIDD for having controverted some of the pet theories of its proteges. This formerly sane journal has of late like Hamlet "put an antic disposition on," the prominent feature of which is to gush at random and call it science; no theories are too visionary, no hypotheses are too impossible for its credulity; it has assumed to itself the lead in all matters pertaining to British Tropical Medicine, and by the extravagance of its views it has already called forth adverse criticism in several quarters.

The *British Medical Journal* tells us that "the subject of tropical acclimatisation has hitherto been discussed mostly by statesmen, geographers, meteorologists, and journalists" and also that, "it appears to us all the more necessary to discuss it from the scientific standpoint."

In this impartial spirit does it cast contempt upon its opponents, and claim to be the only home of science so that we are not surprised when it says, that Mr. KIDD deals with the subject "perfunctorily" and "with a dogmatism hardly warranted by his knowledge of the subject."

But before following the scientific footsteps of the *British Medical Journal* in its attack upon Mr. KIDD, and discussing the arrangements it brings forward in support of the possibility of acclimatisation, it will be well to pause a moment to consider the exact nature of the proposition.

In the first place we may mention that there are many places lying within the tropics of Cancer and Capricorn,

which have climates by no means tropical, such as many of the hill stations of India and the high tablelands of Africa; these of course have nothing whatever to do with the point at issue, nor would we consider it necessary to allude to them, were it not that a contemporary has solved the question of acclimatisation in the affirmative, to his own great satisfaction, by pointing to the possibility of Europeans settling in such pleasant climates.

The question is, can the white man colonise the plains of India and the plains of Africa in the same way as he has done Canada and the United States, not, can he dwell in comfort in the Nigritia, or at Newera Elia?

By colonising in this sense it is meant, not that the white man should be a mere supervisor of labour, but that he himself should be the labourer; that he with his family should take up the land and be tillers of the soil, the hewers of wood and the drawers of water, that they should live there from generation to generation and perpetuate their race without degeneration.

It is of this that the *British Medical Journal* is so confident of the possibility, and the following are some of the arguments it advances. "Setting aside theories," it says "is not the revolution which improved sanitation has wrought in all tropical climates, a striking proof of what can be done to make acclimatisation possible" as a proof of this it remarks that, "The death-rate of European troops in the tropics which used to be from 100 to 129 per 1000, is now as low as 12 per 1000 in India."

The argument appears to us to be about as bad and as weak a one as could possibly be brought forward. Putting aside the fact that the reduced mortality in India is largely due to the mere alteration of the terms of service, the change from long service to short, the condition of the soldier in India is as different from the condition of a colonist as it could well be.

Now the average time that each soldier stays in India is under five years. The strength of the European troops is roughly 70,000 and every year about 15,000 go home. In 1896, 1950 men were saved the chance of dying in the country by being invalided to England, under these circumstances the lowered death-rate can hardly be fairly quoted as evidence in favour of acclimatisation, in as far as it may be attributed to improved sanitation, it must be admitted that amongst the chief causes which have contributed to make India healthier to the soldier, are those which have been directed to protecting him from meteorological influences, such as improved housing, improved clothing, more care in exposing him to tropical heat, and increased facilities for removing him from the elevated temperature of the plains to the coolness of hill stations.

But to all these influences the *British Medical Journal* denies the possession of any noxious properties, in its eyes the all prevailing microbe is the only or chief danger, and sanitation is only sanitation when directed against some micro-organism.

Few hot house plants are more carefully looked after than is the British soldier in India, and the proportion of care lavished on protecting him from microbes, is small, compared with that which, as the result of a dearly bought experience, is expended upon protecting him from the effects of the climate.

Poor as this argument is what are we to think of the

following? "The Englishman transplanted to America and Australia differs already as much from his prototype in physical and psychological characters, but surely he has not degenerated."

The writer we presume refers to the descendants of the "transplanted Englishman" not to the original worthy himself who probably had not time to prove the gospel of acclimatisation by the physical and psychological changes alluded to, and if he had, no doubt he would have ceased to be an Englishman.

But the most extraordinary part of the thing is that the places brought forward to prove the possibility of acclimatisation in the tropics, are not in the tropics at all.

America is a very vague geographical expression, but then we have seen that this journal despises geographers. Well the only parts of America that have been colonised by Englishmen are Canada and the United States and they are both well outside the tropics.

The greater part of Australia lies outside the tropics, and it is in this part only that colonisation has been successful. It is well known that in the tropical parts of Queensland the labour is done by imported blacks.

It is the same with the Boers who are held up as examples of successful tropical colonists, only a very small part of the Boer territory is in the tropics. Such are some of the arguments on which the *British Medical Journal* relies to prove to us the possibility of the acclimatisation of white men in the tropics, nor are the remainder any more convincing.

As a final coup de grace we are informed that "Already more than 10,000,000 white men and their descendants are settled within the tropics." As the *British Medical Journal*, like Dr. MANSON, uses the word tropics in a sense peculiar to itself, it is not worth while trying to test the accuracy of the figures; it is certain however that, to whatever race these white men may belong, they are neither Englishmen nor their descendants.

The theories of the *British Medical Journal* impress us as little as their facts. We are told that, "Dr. SAMSON brought forward a large amount of weighty evidence that the causes of disease, deterioration, and deaths in the tropics are due not so much to the influence of climate as to pathogenic germs" Dr. SAMSON has gained some notoriety for himself by his wild speculations regarding sunstroke, which he believes to be an infectious disease, with a specific microbe of course; but we do not on this account see any reason to accept him as a prophet. The *British Medical Journal* however accepts him blindly and subscribes to his doctrine in the following words.

"There appears to be good reason, however, to believe that the real enemy is the microbe; and, if so we may hope to fight against it in the tropics as successfully as has already been done in temperate zones by sanitation and the gradual acquisition of immunity."

The above sentence has a peculiar ring of Dr. MANSON, and it would not surprise us to learn that the article we are venturing to criticise is from his distinguished pen, which would explain the loose way in which the word tropics is used.

Dr. MANSON appears to have become strangely optimistic as to the possibility of white men colonising the tropics since he has taken up his residence in England.

The views expressed by him, in the introduction to his "Tropical Diseases" are really at the bottom of the whole subject.

"Who can doubt," he says, "that just as the fauna and flora of the tropical world are infinitely richer in species than those of colder climates, so there is a corresponding distribution in the wealth and poverty of pathogenic organisms?"

We do not believe that there is a particle of evidence in support of this wild generalisation.

From all that we know of the primitive inhabitants of tropical regions, their diseases are fewer in number, and simpler in nature than our own. The extraordinary rapidity with which their flesh heals after wounds of the most severe description is universally admitted, and affords strong *prima facie* evidence of the absence of virulent micro-organisms.

What diseases have the savages of Africa to compare in infectiousness or destructiveness with our exanthemata? Some of the African tribes are remarkable for their splendid physique, while in health and longevity they rival any European people.

It is all nonsense to talk of there being a poverty of pathogenic organisms in temperate climates, and a wealth of them in the tropics; history tells us that destructive diseases have been more frequently conveyed from whites to blacks, from civilised to uncivilised communities than the reverse.

To ascribe these things to acquired immunity is merely a blind or an admission that the savage has succeeded where the white man has failed.

—:—

QUACKERY AND QUACK ADVERTISING IN INDIA.

On the 17th May last, Sir WALTER FORSTER, M.D., in the House of Commons, asked the Secretary of State for India if he was aware that at present uneducated and unqualified persons have as much right to practise medicine in India as fully qualified practitioners; and whether in view of the danger to which the Indian People are thereby exposed, he would consider the advisability of instituting a system of registration for medical practitioners, similar to that which exists in Great Britain and Ireland.

LORD GEORGE HAMILTON replied; "The answer to the first branch of the question is in the affirmative and that to the second branch in the negative. It would be, in my judgment, impossible in the present condition of India to prevent the people of that country from resorting to native practitioners, even though they may be regarded by Europeans as not fully educated or qualified for the work they undertake."

The reply of the Secretary of State for India appears to call for one or two remarks.

In the first place all native practitioners in India cannot be looked upon as unqualified. Is LORD GEORGE HAMILTON aware that in India, in the Punjab University, there is a special course for students of Oriental medicine, where a knowledge of the Yunani or Vaidya systems of medicine is insisted upon and where examinations are held for Hakims and Vaidyas, Umdat-ul-Hakama or Bishak, Maha-Bishak and Zohdat-ul-Hakama.

Men who have attended such courses and obtained the above titles, though native practitioners, cannot be

held to be unqualified, and they are quite as entitled as anyone else to be protected against the invasion of their sphere by impostors.

In the second place if the reason given by the noble Lord was generally accepted as rendering registration either unnecessary or impossible, it must be clear to the meanest intelligence that registration would exist nowhere, for in no country in the world is it possible to prevent people from resorting to unqualified and uneducated quacks and swindlers for the treatment of their ailments.

Quackery is rampant in every civilised country in the world, and in spite of the crusade against it, which becomes keener every day, it thrives. Its roots derive their nourishment from the superstitious of the dark ages through which we have passed, and its victims are attracted by the gaudy flowers of its fraudulent advertisements.

Nothing but gradual enlightenment and education can overcome the dense ignorance, superstition and love of the miraculous, which lead fools to pin their faith upon the glaring advertisements of unscrupulous charlatans.

It would be an interesting study, but foreign to our present purpose, to trace the evolution of quackery, to point out its insidious wiles, and to show how it appeals to and feeds, like a loathsome parasite, upon the weakest and most unhealthy parts of human nature; the morbid appetite, the depraved imagination, the diseased mind and the illused and suffering body.

Quackery is as old as the human race, and the struggle against it must be long and bitter before it finally succumbs; and yet, although amongst educated men there can be no question of the ungauged amount of harm it does, in spite of the voice of civilised humanity being against it, we see the Secretary of State for India in his official place in the House of Commons, proclaiming its legalisation in India.

LEGAL QUACKERY.

For this is what the Secretary of State's answer plainly amounts to, neither more nor less. The status of the Quack in India is as good, according to him, as that of the fully qualified medical practitioner.

India is unique in being the only country under civilised rule where quackery is legal; it is certainly curious that such a retrograde departure could have been inaugurated at a time when the cry for reform and improvement in all things connected with medicine, echoes loudly from every country where the English tongue is spoken.

More curious still is it to note that this strange declaration has been passed over in silence by the English Medical Press. This strange silence is certainly not encouraging to the cause of Medical Reform in India.

Let us now turn to the consideration of a certain class of quack literature which is scattered broadcast throughout the length and breadth of India, under the guise of some of these systems of native medicine which LORD GEORGE HAMILTON is so anxious to foster and cherish.

In the first place we have a pamphlet of 56 pages which calls itself the "Ayurveda Sangraha." "A monthly Journal of Medicine." It is nothing more than a mass of quack advertisements, wretchedly printed and adorned with grotesque illustrations.

It is conducted we are informed by KAVIRAJ NAGENDRA NATH SAIN GUPTA.

The following are the positions assumed by himself and his associates, and are as follows:—
 "Government Medical Diploma holder. Member Surgical Association (London), Society of Chemical Industry, (London), Paris Chemical Society, Indian Medical Association, Calcutta Medical Society, Author of "Kaviraj Siksha," "Daktari Siksha," and "Hindu System of Medicine," "Lala Baidant Lal Institution," Delhi."

This man claims to hold a Government Medical Diploma, and this claim has been accepted and reiterated by almost the whole of the Indian lay press and by the leading Calcutta daily, the *Englishman*.

As far as we can ascertain the claim is unfounded, he has no recognised university or collegiate diploma in medicine or surgery, and is apparently an advertising quack.

It is true that his name is at present in the roll of membership of the Indian Medical Association, he there appears as an L. M. S. This is a degree granted only by the Calcutta University, but the name of Kaviraj N. N. SEN GUPTA, is not to be found in the Calcutta University Calendar.

The presumption is that he has at times illegally assumed this title and the attention of the University authorities and of the Council of the Indian Medical Association is therefore drawn to the matter, and the result we hope to be able to publish at an early date.

As for the other Societies to which he claims to belong, we know nothing about them, except that they have no standing in the medical profession.

Fifteen pages of the pamphlet before us are taken up with press puffs of the most plausible description, to which pernicious system, as we have remarked, the Calcutta *Englishman* lends itself. The changes are rung on the numerous titles he lays claims to and his books are reviewed.

We hear learn that the "Daktari Siksha," "is a big Vade Mecum of the Medical Science," and that the language is easy, clear and melodious," another paper says "the language is easy, sweet and chaste" (whatever that may be) and that Baba K. N. N. SEN GUPTA "has begun to create an epoch in the medical world."

The *Hindoo Patriot* tells us that the "Kaviraj Siksha" is a compilation from various well known Ayurvedic works; somewhat unkindly it ends its review of the book with the remarks, "Kaviraj NAGENDRA NATH SEN has a fair knowledge of English. With slight assistance he may achieve the desideratum," even in time we suppose he may come up to the standard of the *Hindoo Patriot* itself.

The *Pratibha* says "he is a specialist in curing many incurable diseases." The *Pratibha* is nearer the mark than it thinks, for this is exactly what he professes to be.

The love of natives for a title of any kind is forcibly brought to notice by the constant repetition of the phrase "he is a Government Medical Diploma holder."

We must not omit to mention that Kaviraj N. N. SEN GUPTA poses as a philanthropist. We are told that he has started a "Free Ayurvedic Institution where lessons in Western and Eastern medical science will be imparted to boys free of charge by competent teachers of eminent scholarship." He does not, we learn, want pecuniary (sic) aid, but only "the sympathy and moral support of the aristocracy and gentry of India."

The following is an extract from the *New York Medical Record* of this age when Eastern medicine was first introduced (sic) by the Great German Philosopher, BROOKLYN (sic) in his ecstasy of admiration for the Spaniards he produced a wonderful influence over Western thought.

THE LIEUTENANT-GOVERNOR'S NAME BROUGHT IN.

What astonishes us most of all in the pamphlet before us, is to find that even the Lieutenant-Governor of Bengal is made to subserve the advertising tactics of this man.

Occupying the most prominent place in the front page, we are given the following "copy of a letter from the Private Secretary to His Honor the Lieutenant-Governor of Bengal," dated Belvedere, 30th April 1898:—

Sir,—I beg to acknowledge with thanks the receipt of four bottles of your Kesarjan Oil forwarded for His Honor the Lieutenant Governor with your letter of the 29th instant.

Yours faithfully, A. H. GAYER, *Private Secretary*.

Surely it is a monstrous and scandalous thing that the Lieutenant-Governor should thus lend himself, through the medium of his Private Secretary, to assist the tricks and knavery of any unscrupulous charlatan.

We are not uncharitable enough to imagine, or even to hint, that Sir JOHN WOODBURN indulges in quack remedies himself from choice, but that his Private Secretary Mr. GAYER should be fooled, by a present of four bottles of oil, into letting the Lieutenant-Governor's name appear throughout India as a patron and supporter of a common quack, is discreditable in the extreme, and we feel certain that the use made of his name only requires to be made public to be instantly repudiated.

In our next issue we will sample some of our Quack's much vaunted remedies and then pass on to others of the same fraternity.

ATYPICAL MALARIA AS SEEN COMING FROM OUR MILITARY HOSPITALS.

ONE of the results of the American War in Cuba has been the importation of cases of malaria into New York, an interesting communication concerning which appears from the pen of Dr D. W. WYNKOOP under the above heading in the *New York Medical Record*.

"For the second time in the history of this country," Dr WYNKOOP says, "a manifestation of malaria, which formerly was rare in all our Northern and Western States, to-day is common there."

Its severity, its fatality, and close resemblance to typhoid fever during certain stages are marked features of the disease.

The following description of the algide form is drawn from the cases that have been under his own observation supplemented by information derived from those in charge of hospital camps.

Definition.—An infectious disease characterized by: (a) sudden onset with few prodromal symptoms; (b) paroxysms of fever with no regular type as far as time is concerned; (c) the typical malarial chill usually absent; (d) gastric disturbance with enteritis;

(6) a tendency to coma and death in the third or fourth attack; (7) skin disturbances; (8) the crescentic form of this hematozoon always found; (9) the presence of this form of plasmodium in the blood of those apparently cured of their attack.

Etiology.—One may question the mosquito theory of entrance of the organism into the body, as most of those recently active in the Cuban war are unanimous in saying that they encountered few mosquitoes while on the island.

Few sailors have contracted this algide type of malaria, except those who have had considerable shore duty while in Cuba. It has been practically confined to those in the army who have lived in Cuba, though some have undoubtedly contracted the disease while in camp at Chikamauga. In Alabama and several of our Southern States this form of fever exists, although it is rarely spoken of as malarial fever; they say there that a person dies of a congestive chill.

Duration of Incubation is very uncertain. Many who have gone through the campaign with no sign of the disease have had it develop after their return to the States. This may be accounted for by the fact that it was the practice of most of the soldiers to take from fifteen to thirty grains of quinine a day while in Cuba, but on their return home they ceased taking the drug. It is possible that this amount of quinine, although taken at irregular intervals, was sufficient to keep the disease from manifesting itself, yet not sufficient to eradicate it.

Symptoms.—Mode of onset. The patient generally says that he was feeling perfectly well up to 11 A. M. He went in for bathing and returned to mess in an hour. After dinner he began to feel weak and he went to his tent to lie down. By 4 P. M. his head felt dizzy and he had pains in his back and legs. This pain continues with increased severity and his dizziness changes to headache. On his admission to hospital at 8 P. M. it will be found that his temperature is 15° F., his pulse 120, and his respiration 28.

Chill is usually slight and often absent.

Fever.—The rise in temperature is usually a rapid one ending at 105° F., though in many cases it may go as high as 106° F., and in some a little higher; it ranges between 103° and 106° F. With the end of the rise in temperature we are not to expect a rapid fall. The temperature may stay at this high point or near it for an hour or two, and then slowly fall, taking from ten to twenty hours before it gets near normal. A drenching perspiration accompanies this fall and keeps up even after the temperature is below 99° F. The patient lies in a state of profound prostration. The second day after this we find an afternoon rise in temperature up to about 101° F. This continues with a morning fall for possibly a week or ten days, if no quinine has been administered during this period. The second high rise in temperature should be looked for about this time. It will act in the same way as the first, with the difference of being probably higher with greater prostration. There is no fixed duration of time between the high temperatures. As a rule it is from five to ten days, apparently being influenced by the general condition and resistance of the patient. We have a third high rise and

usually a fourth, the intervals becoming longer and shorter. Death usually follows the fourth rise of temperature.

Under the action of quinine (given hypodermatically by preference when we find hyperpyrexia) we are able to control this temperature and usually prevent any excessive elevation of temperature following the initial attack. It is on the strict and prolonged administration of this drug that success in dealing with cases depends.

ABDOMINAL SYMPTOMS.

The spleen is always found enlarged and more or less sensitive to the touch. In percussing over the abdomen we find tenderness in various parts—in some cases shifting from day to day, in others showing a persistence over the ileum—a point which causes one to think of typhoid fever, especially in consideration of several other symptoms I shall mention later on. The second day after the initial high rise in temperature we have usually gastritis and enteritis as complications. In many cases I have seen the stools almost characteristic of typhoid—the pea-soup variety and frothy. Under the action of quinine the stools become gradually darker and more firm. The patient's tongue is heavily coated but is moist. In many of the cases the kidneys refuse to do proper work, and in one I had suppression of urine for thirty-six hours.

MENTAL CONDITION.

After the first rise and fall of temperature the patient is left in a very apathetic and dejected condition. He takes little interest in his surroundings, and sleeps a good deal of the time. He has no desire for food but is always thirsty. With the second rise in temperature he becomes delirious. With the third and fourth he becomes comatose. Many patients who are apparently cured (though in reality not), after having been up and about for a week or two, will be brought into the hospital in a comatose condition, this having come on within less than an hour, and in this condition they may expire. This is by far the most important feature to remember in connection with this atypical form of malaria. The blame lies on the physician who allows his patient to go about before the protozoon is eradicated from the system. Many sudden deaths of soldiers on furlough in our cities can be put down to this score.

SKIN DISTURBANCES.

In some cases there has been an erythematous rash of short duration on various portions of the trunk, often on one hip. This rash was followed by itching of the part.

BLOOD EXAMINATION.

It showed the plasmodium malarie in every case. It differed from that in our ordinary form of malaria by the constant appearance of the crescentic protozoon. The examination of the blood of those who had one or two previous attacks and were at the time of examination feeling perfectly well and doing their ordinary work, showed in several cases the crescentic form of the protozoon. From this we might justly infer that patients having had one or more attacks of this atypical form of malarial fever could not be considered free from the same, till examination two months after the last dose of quinine showed their blood free from these organisms.

DIAGNOSIS OF MALARIA

One can understand how a physician could mistake this form of malaria during periods of its stage for typhoid fever. In fact I am convinced that many are at the present moment undergoing treatment for a supposed typhoid fever, when in reality the above condition exists. Without the knowledge of incubating and expiring these men have gone through, and on account of their lowered vitality, we are more prone to make the diagnosis of an irregular typhoid fever than to consider the disease as a possible malaria. A examination of the patient's blood will enable one to arrive at a correct diagnosis.

Malarial fevers of this very severe and fatal description are rarely reported even from the most malarious parts of the Indian Empire.

The above description, however, tallies very closely with that given by Manson, ("Tropical Diseases") of malignant infections (Acutive-Ataxmial of the Italians). According to him, the crescentic form of the protozoon is only present in malignant infections. It does not cause fever, it is usually associated with marked cachexia, and not readily influenced by quinine. Further in such cases the fever is liable to be very irregular, the rigor stage to be less marked, the pyrexial stage prolonged, and there is a great tendency to relapses at more or less definite intervals of from eight to fourteen days. While at any time pernicious symptoms of the gravest character may declare themselves.

It is to be remarked that the evidence, as far as it goes, is against the idea that mosquitoes were in any way responsible for the infection.

Fever of this description in the Southern States are spoken of as "congestive chills." In connection with this nomenclature it is noteworthy that in our author's cases the disease usually appeared shortly after bathing, apparently irrespective of the age or condition of the parasites. The course of events appears generally to have been,—patient perfectly well up to 11 A.M., then went in for bathing, at 4 P.M. general pains and dizziness and at 8 P.M. high fever.

We read, "that it was the practice of most of the soldiers to take from 15 to 30 grains of quinine a day while in Cuba." We presume that most of the men who came under our author's care had done so, for otherwise the fact would certainly have been mentioned, yet even in these large doses quinine appears to have failed to prove itself an effective preventive.

The author lays particular stress upon the close resemblance to typhoid, but does not mention if the typhoid bacillus was looked for.

The whole subject of this Atypical form of Malaria, closely connected with the crescentic form of the protozoon is extremely interesting, and now that attention has been so ably drawn to it by Dr. Wraether we will look for some further enlightenment from our energetic confrere in New York.

INDEPENDENT MEDICAL DIPLOMAS IN INDIA

In our correspondence columns will be found a report of a most pernicious effort to introduce into an already over-burdened country of quacks and uneducated practitioners a diploma-mill for producing all who desire to apply for them, certain "diplomas" to practice medicine. These documents are to bear the hall-mark of America, a country which, though for some little time had the unfortunate reputation of harboring a few illicit traders in "diplomas" has not only fairly wiped out the reproach, but has advanced the standard of its colleges and its teachers, to a very high and enviable level. It is a disgrace to our great American cousins that their consular representatives in India do not instantly give a decisive blow to these questionable fortune hunters, who in the name of America, seek to delude Indian medical students into purchasing parchment and going through the veriest mimicry of a so-called "examination," in the belief that some genuine "College" in that far off land is conferring on them on the real dignity of a Doctorate in Medicine. We appeal to American Medical Colleges and to American Consul Generals to expose and drive out these fraudulent impostors. Apart from these so-called American diploma sellers in Bombay, and very honorably distinguished from them, we find two Societies in Calcutta honestly endeavoring to struggle into the position of teaching medical corporations. We refer to the Calcutta Medical School which is a fairly flourishing and honorably conducted institution, and the "College of Physicians and Surgeons of Bengal." The Calcutta Medical School is a small but well-conducted vernacular school. It is officered entirely by Bengalee gentlemen, all of whom are graduates of the Calcutta University. It was established 18 years ago in Lower Circular Road. All the subjects which form the curriculum of the Native Government Medical School—The Campbell Medical School of Sealdah—are taught in it. For some years now this indigenous independent school has been granting diplomas to its alumni.

This diploma—the L.C.M.S., or Licentiate of the Calcutta Medical School—is given after four years of study, and candidates have to pass a very fair examination before they receive this passport to practice their profession. The test applied, is, we believe quite equal to that of the Campbell Medical School, which seems to serve the same purpose as the Calcutta Medical School, namely, that of educating a class of vernacular practitioners, whose vocation is among the poorer classes of natives in the rural districts, or who enter the subordinate native service of Government as hospital assistants. The Calcutta Medical School has made material progress during the past two years, for though not nearly as well equipped as the Campbell Medical School, and though not possessing such an excellent hospital for clinical teaching, it now owns a complete though small arrangement of glass rooms for anatomy, dissections, physiology, chemistry, materia medica, pathology, as well as an out-door dispensary. It has a small hospital for students beds for its students are permitted to attend the clinical facilities offered by the various Government native hospitals in the city. Altogether we feel that though the Calcutta Medical School is sadly in need of immediate and urgently necessary improvement in every

There is no doubt that the Bengal arrangements for the medical education of the natives are of the most important nature. It is an established fact that the Government of Bengal, in its efforts to improve the medical education of the natives, has made a most commendable and praiseworthy effort on the part of the Government, which is deserving of encouragement and support both from the public and from the State.

There is also in the same street another indigenous institution styled "The College of Physicians and Surgeons of Bengal." Here too we find enterprising Bengalee gentlemen, all graduates of Indian Universities and some with British diplomas, making an honest effort to raise a teaching medical institution, with higher and more ambitious aims than its indigenous neighbour to which we have referred. We have recently inspected both these schools and we must admit that while admiring the boldness and enterprise of their originators, we were struck with the apparent uselessness of having two such societies. The School is flourishing and gives abundant evidence of financial prosperity, for it has 400 students on its rolls, while the "College" seems to be in a most deplorable and unpromising condition. We learnt that it had been in "existence" for 2½ years, that now there were 40 students on its rolls, who paid 3 Rupees a year for their tuition! that seven Babus were their teachers. The class rooms, the furniture, the "bottles," the stuffed monkeys, bears, &c, and the dingy, dirty ghostly appearance of the "rooms," the filthy dirt-laden wilderness of waste land around the barn-like building, styled a "College," are all too torturing to describe. How on earth a single Bengalee "student" attends such a place, is beyond our imagination to conceive. Clearly, nothing is or can be "taught" to men in such a place, and yet we found "Notices" in a box with a glass paneled front announcing that certain "students" were "requested" to appear at the First L C & P Examination. So that this "institution" intends granting Diplomas. The whole farce seems too absurd for serious attention. Yet the subject is fraught with the most dangerous warnings to the public and to the Government. We are strongly of opinion that these two "schools" should unite. It is utterly impossible for the "College" to do any good, but united to the "School," a system of education could be usefully carried on and after a time an examining body could be formed, supervised and controlled by Government, and granting a certificate or diploma of qualification to practice Medicine, Surgery and Midwifery. We are further strongly of opinion that the Government should retire from educating this lower grade of practitioners and abolish its paid staff at the Campbell Medical School and Hospital, handing over its own institution to the combined staff of the Calcutta Medical School and its more ambitious though less successful neighbour. Such a step would greatly encourage indigenous medical enterprise and open a very fruitful avenue for the natural development of medical science among the natives of Bengal.

The whole system of the education of the lower ranks of medical practitioners and medical subordinates in State hospitals and dispensaries, badly and urgently requires the most serious and careful attention of the Government, and it is our belief that the Government should follow the suggested model of the Indian Medical Association, which has already secured an entire scheme for the reform of the medical education of the lower ranks of the medical profession before the Government.

CURRENTS AND NEWS

PROFESSOR OF SURGERY AND DEPUTY SURGEON IN CALCUTTA

We learn from Simla that Dr. R. D. MURRAY is confirmed in his officiating appointment as Professor of Surgery in the Calcutta Medical College. He is not to hold the position of First Surgeon to the Medical College Hospital. Dr. MURRAY is to be one of the surgeons but not chief surgeon. The titles of First and Second Surgeons are henceforth to be abolished. This is the "top to bottom" which the Government of India has thought meet to throw down in mitigation of a most unpardonable and unexcusable blunder. The highest principles of efficiency, the sacred demands of justice, the pre-eminent claims of the hundreds of medical students, who trusting to the honesty of the medical administration of this country, entered the College in the firm belief that they would be taught surgery by a skilled and experienced surgeon, have all been sacrificed and flung, before the altar of that monster goddess of Indian officialdom, INTEREST.

On behalf of every medical practitioner, both European and Indian, and on behalf of every student of the Calcutta Medical College, we protest against the action of Mr. RISLEY, K.C., of Bengal, and also against the conduct of SIR JOHN GARNHAM HARVEY in this matter of Dr. MURRAY'S appointment as Professor of Surgery and as the representative Surgeon of this great city. Never was a worse job perpetrated, though many iniquitous jobs have been done in the Calcutta Medical College and Hospital before to-day. There is no excuse for this gross injustice to Calcutta, for the medical authorities were only too well aware of the transparent unfairness of the man for his unfortunate promotion. Surely the records of the Office of the Inspector-General of Civil Hospitals in Bengal and the written objections forwarded to the Office of the Director-General of the Indian Medical Service, bear us out in our contention. But we have not as yet done with this unavourable piece of maladministration. The telegraph warned Dr. HARVEY of the colossal folly of his office in confirming Dr. MURRAY'S nomination, and there is therefore nothing to plead in extenuation of this educational blunder, which places the reputation of the Calcutta Medical College at a terrible stake, by making laughing stock of its surgical representative, for we venture to state that no European practitioner in Calcutta feels the faintest confidence in calling in the consultative surgical genius of the *Gazette* manufactured, "professor" whom it hath pleased the RISLEY *own* HARVEY cabinet to honor.

Calcutta is now in the unenviable position of having no "Star" (Official "Star" we mean of course) in its Surgical or Medical armament, and like the Macedonians we might well raise the missionary cry to London, Dublin and Edinburgh, "come over and help us," for the city is in dire straits for an official consulting surgeon and a consulting physician, whom the Mahatmas of Simla, Messrs HARVEY and RISLEY have pitched G. P. (General Practitioner) into the dignified position of Professors and Consultants. Mistaken this is to place powerful weapons in the hands of the adversaries for medical reform in India, for they forge the dynamite bombs that will soon explode and with their shattering and devastating destruction, shatter every vestige of the sham and monopolies of the Indian Medical Service, that for nearly a century have dwarfed the real growth and development of medical science and of the independent medical profession of this country.

THE CALCUTTA "ENGLISHMAN" ON DR. MURRAY'S APPOINTMENT.

SINCE writing the above, we find the *Englishman* of the 9th November offers an "apologism" for Lieut.-Colonel MURRAY's appointment. It states among other matters that Colonel MURRAY studied *modern surgery* under "Lord" LISTER in 1873? That must have been modern surgery with a vengeance. It reminds us that there was then no "Lord" of "antiseptic" surgery and that the appearance of "aseptic" surgery is quite as modern as the appearance of the "Lord" at whose feet our "modern" M. B. of 1873 learnt only the A. B. C. of what most surgeons know and understand as modern surgery. We are further reminded that in all probability the writer of the MURRAY 'apologism' and the subject of his "ditty," might both be engaged to indie a new version of the story of the triumphal entry of the animal tribe into Noah's Ark having special reference to "modern" surgery in Calcutta. It might begin with—

Murray and the *Englishman* entered the Ark,
Calcutta looked on and wondered,
Harvey and Risley worked in the dark,
And Surgery was "modernly" murdered

In order to correctly and clearly expose the "flaws" of the advertisement we refer to, (and which the *Morning Post* repeats) we reproduce *verbatim* the enlogistic paragraph on Dr. MURRAY's appointment referred to above —

"Lieutenant-Colonel B. D. MURRAY, I.M.S., who has been confirmed in his officiating appointment as Professor of Surgery in the Calcutta Medical College and First Surgeon to the Calcutta Medical College Hospital, has a distinguished record. He commenced his career as an Honours Graduate in Medicine and Surgery in the Edinburgh University in 1873, having studied modern surgery under its founder, Lord LISTER, and in 1874 was appointed Senior Resident Physician and Clinical Tutor in the Edinburgh Royal Infirmary. He then resolved to enter the Army and in 1875 passed into Netley at the head of the list. Finding in a Military Hospital insufficient scope for his energies, he in 1876 entered the Civil Department under the Bengal Government, where he has since remained except for a brief interval in 1886, when he was ordered to Burma on active service. In this short experience of Field duties, he was posted to the charge of a Field Hospital at Mandalay, and in that capacity performed his new duties in a fashion that procured him mention in despatches. Excluding this period he served from 1885 to 1888 as First Resident Surgeon in the Presidency General Hospital and Superintendent of Asylums. In 1890 he was appointed Civil Surgeon of Gaya, being afterwards appointed to the important post of Civil Surgeon of Howrah. During the absence on furlough of Colonel O'BRIEN, he officiated for him at the Medical College and Hospital."

Now after all we have said in objection to Dr. MURRAY's nomination, we feel compelled to allude in explanation to the above paragraph. To start with, this statement was never written by any member of the *Englishman* staff. It emanated either from the Director-General's Office at Simla or from some highly interested "medical" personage in Calcutta to whom these peculiar little "personal" details were intimately known. In whatever way they may temporarily serve their advertising purposes, we feel bound to challenge the statements of the *Englishman* on purely public grounds, for we hold that Lieutenant-Colonel MURRAY I.M.S. is not qualified to be either a "professor" of surgery nor a surgeon to an educational hospital. We once more affirm that personal-

ly we have nothing against Dr. MURRAY. He has been a general practitioner, we give him all the credit due to a good civil medical officer, his character is unimpeachable and his many gentlemanly qualities and genial kind ways are worthy of a high measure of praise. It is a fatal mistake, however to endeavor to justify the culpable action of the Bengal Secretariat and the Medical Administration at Simla, by misleading the public by means of statements in the lay press which are tantamount to a *suggestio falsi* by a *suppression veri*.

The *Englishman* begins with a statement which is false. It says (1) "Lieutenant Colonel B. D. MURRAY has been confirmed in his officiating appointment as Professor of Surgery and First Surgeon to the Calcutta Medical College Hospital." Now to quote the true "*Gazette*" notification from the *Pioneer*, we find —

"Lieutenant-Colonel B. D. MURRAY, M.B., I.M.S., (Bengal), is confirmed in the appointment of Professor of Surgery, Medical College, Calcutta, and *ex-officio* Surgeon to the College Hospital."

It is therefore *ex-officio* "Surgeon" and not "First." It makes a difference, and an important and significant difference in view of all that has been written in this journal against Dr. MURRAY's fitness for the posts he has been "helped" into. (2) The *Englishman* says Dr. MURRAY "has a distinguished record" Where, when and how? Look at the available records of professional work—the medical press, the medical directories, the annals of medical and surgical science—and we look in vain for a "*record*" of any kind, but as to '*a distinguished record*,' that is indeed a flight of fancy. (3) The *Englishman* says "He (Dr. R. D. MURRAY) commenced his career as an Honours graduate in Medicine and Surgery in the Edinburgh University in 1873." We have searched in vain in the official record of the medical profession (the Medical Register of the General Medical Council) for the admission of the fact that ROBERT DAVIDSON MURRAY M.B., M.S., Edin., who was registered on the 17th November 1873, (just a quarter of a century ago) is an "Honours" graduate. Nor do we find any such record against his name in that other unerring register—CHURCHILL'S Medical Directory. Where did the *Englishman's* paragonist gather the flattering information that R. D. MURRAY was an "Honours" man? His professional '*record*' in both these professional guides is as barren and waste as the sands of Sahara. And Dr. MURRAY is not M.D. of his alma mater yet. (4) The *Englishman* goes on about RISLEY's "pet surgeon" "having studied modern surgery under its founder, Lord LISTER." Shades of SYME deliver us! The "Surgery" of a quarter of a century ago is "modern" to the *Englishman* and its paragonist, but who is he who knowing anything of the past five years, will call the expoded teachings of Mr. LISTER of 1873 (the "Lord" of to-day) "modern." To prove that Dr. MURRAY, if he trusts the *Englishman's* valuation of the "modern" surgical teaching he underwent in Mr. LISTER's wards in the Edinburgh Infirmary in 1873, is trusting to a broken reed, we have but to review the history of LISTER's work at and after that period. In 1875 he published his first book on "The Germ Theory of Fermentative changes," and up to 1879 his theories were not only disbelieved but very hotly disputed. LISTER, as everyone who knows any thing of "ancient" surgery knows, changed his ideas very materially, so materially indeed that all his pet schemes for surgical treatment, the schemes of 1873, that modern era of the *Englishman* and "Professor" MURRAY, have been absolutely abandoned for a technique of a totally different character. (5) "He" (*Principles*, MURRAY) "then resolved

under the name and in 1878 passed into Netley at the head of the list," in spite of the *Englishman* once again, and once again a "false note." The Army List tells us that Surgeon-Lieutenant-Colonel GEORGE RANKING stands at the head of MURRAY's "list" as the Harbert Prisoner, so the suggestion of the *Englishman* that MURRAY passed out of Netley "at the head of the list" is wrong and calculated to mislead the Calcutta public. Now we think we have sufficiently exposed the "statements" of the *Englishman* and we will for the present allow the stupidity and the foolishness of Messrs. RISKY and HANBY to await the exposures that their folly necessitates being made both at the India Office in London, and in the Chamber of the General Medical Council of Great Britain.

THE BACTERIOLOGY OF CIRRHOSIS OF THE LIVER.

In our pages, October 1st 1898, we announced that Professor J. G. ADAMI of Montreal claimed to have discovered a distinctive microbe in cases of Hepatic Cirrhosis, some further information on the subject was communicated to the meeting of the British Medical Association at Edinburgh, in a paper by the discoverer.

The paper was read by Professor WM. OSLER of Baltimore.

It was pointed out that not a single observer had been able to produce in animals, by means of alcohol, anything at all resembling the extreme deposit of fibrous tissue met with in typical hobnailed liver.

On the other hand, evidence was accumulating, especially in India, that extreme cirrhosis may attack children and adults who have never taken a particle of alcohol.

Some French pathologists, notably HANOT have regarded the enlarged cirrhotic liver which it associated with jaundice as being of infectious origin, and have made use of the term, *le foie infectueux*.

The author's first researches were made in connection with a very remarkable disease affecting cattle in a limited area in Nova Scotia, the so-called Pictou cattle disease, of which the main lesion is a singularly extensive cirrhosis of the liver. This disease appears to have been endemic for forty years in this district, slowly spreading from one animal to another. "The first symptom noticed is a bitterness in the milk and in time the beast dies slowly from exhaustion." The author killed and examined some thirty animals, the main lesions being an extreme condition of generalised hepatic cirrhosis, not only periportal but pericellular, the organ being enlarged and smooth; the gall-bladder was full, and foci were stained and a moderate amount of ascitis was present. Numerous follicular ulcers were present in the fourth or true stomach. These gave the impression that the earliest lesions are the gastric changes, which are followed by the infection of the abdominal lymphatic system and portal area. The spleen was not markedly enlarged. From all the animals a characteristic micro-organism was obtained. It was a polymorphic organism, its most usual form being a short bacillus with polar staining, resembling in some respects the micro-organism of hemorrhagic septicemia in the lower animals, but differing in essential features. It was pathogenic for rabbits, guinea-pigs, and mice. The author was struck with the clinical similarity between this disease and portal cirrhosis in man, and he has since endeavoured to reveal a microbe in cases of the latter. In one case a microbe was procured, but it died on the fifth day. The chief difficulty lay in the staining of the micro-organism in the tissues, all colours tried having faded so rapidly. This was overcome by bleaching very deeply stained sections in the sunlight for a short time daily for two weeks or more. In this way, using carbolic fuchsin, the author had been able to discover the

same characteristic organism in the cells of all the cirrhotic livers he had examined during the last three years—26 in number—whether of the small chenupan type or the large hobnailed type, whether associated with jaundice and without ascites or associated with ascites and without jaundice.

The microbe is extraordinarily minute, requiring some experience on the part of the observer and the highest powers of the microscope ($\frac{1}{10}$ or $\frac{1}{15}$ in.) to discover it in the liver cells, in which, however, it is to be found in great abundance. According to the depth of the stain it does it appear, either as an ovoid bacillus (which might easily be mistaken for some stained deposit in the liver cells) or as a minute diplococcus surrounded by a distinct halo. The author knows of no organism so minute, save that recently described by NOCARD and ROUX as being the causative agent of the contagious pleuro-pneumonia in cattle, and the strain upon the eye of the observer is very severe. The question as to whether the micro-organisms in the human and bovine livers are identical is impossible to decide absolutely at present. It must suffice for the present to state that a characteristic microbe is present in the Pictou cattle disease—a disease having certain close resemblances to progressive cirrhosis of the liver in man—and that large numbers of a micro-organism have been revealed by special methods devised by the author in the lower cells in cases of cirrhosis in the human being; and, finally, that these two micro-organisms greatly resemble each other under the microscope.

In the discussion which followed, Dr. ROSENSTEIN (Leyden) thought that alcohol as a factor in the production of cirrhosis of the liver was very much overrated. In Holland, where enormous quantities of alcohol were drunk, cirrhosis was not met with in like proportion—Dr. OSLER (Baltimore) thought that the possibly bacterial origin of some kinds of cirrhosis was worth bearing in mind.

THE NEGRO DEATH-RATE IN AMERICA.

TIME was when the alarming increase of the Negro population in America filled the statesman and philosopher with the gravest anxiety, and was supposed to be pregnant with the most serious danger to the future of the white race; now the outlook appears to be entirely the other way.

It is no longer the wonderful prolificness of the negro which is attracting attention, but on the contrary his excessive death-rate.

At a conference held at Hampton by leading members of the negro community, a paper discussing this subject was presented by Dr FURNESS J. SHADD, of Washington.

He pointed out that even under the most favourable sanitary conditions, the death-rate of negroes is more than double that of whites. He continued: "Among the most fruitful causes of this alarming death-rate are the following: Infant mortality, tuberculosis, scrofula, specific infection, gastro-intestinal diseases, heredity, and environment. . . . My observation leads me to believe that more factors inimical to the race are found within than without." "Consumption is the greatest enemy the negro has except his vices. . . . My experience teaches me that the negro cannot stand local tuberculous infection without running great risk of pulmonary complications, and, furthermore, I think that the mulatto is more susceptible than are the blacks."

"The condition of the negro in all the large cities is a theme worthy the attention of each of us. I know him as he is under the shadow of the goddess of liberty within the District of Columbia. The habits, the disposition, the clannish congregation of most of the race, compel them to inhabit parts of the city densely populated, from which they may easily go at all hours of the night from home to home, from church to

church, to moribund spirits, who only desire to die, to chase out a more living, with confidence that they work for the gratification of their pleasures. Hence we find them living in alleys and courts, where numbers of more than a dozen often occupy very narrow quarters. The sanitary conditions of these houses are frightful. Can we wonder that death claims many who are so situated?

Such are some of the causes mentioned by Dr. SHADD to explain the decadence of the American Negro. The question from the scientific aspect is one of the deepest interest.

At the present moment we have enthusiasts in England proclaiming their new doctrine, that the proportionately larger number of microbes in the tropics is the only bar to their colonization by white men; here we have the reverse case, the Negro who can flourish in the intensely microbic tropics degenerating and dying out in the comparatively microbe-free regions of the Southern States.

That races die out when great changes are introduced into their social conditions, and when they are suddenly brought into contact with, what we call, advanced civilisation, is beyond contention, but we think that some more convincing explanation than the microbe one is necessary to account for these things.

RACE INCIDENCE OF PLAGUE IN BOMBAY.

AN endeavour is made in the final Report of the Bombay plague committee to assign a cause for the different degrees of severity, with which different sections of the population suffered from the disease.

It is pointed out that the Hindus of Western India take their origin from two territorial divisions:—1, Maharashtra and Carnatic, and 2 Gujarathi, and the varying climatic and physical conditions of these two territorial divisions have their effect on the constitution and character of the inhabitants.

The Hindu traders of Mandvi were the first sufferers, and in the first two epidemics well-to-do Gujarati Hindus suffered more than the corresponding classes from other districts.

The excessive mortality amongst the Gujarates is ascribed by the Report to "want of nervous vigour in their soft fleshy bodies, and perhaps to the indoor life that many of them lead."

Of all classes the Jains suffered most, the following is the reason given:—"The true explanation seems to be that while in the census of 1891, the name of Shravak, with a total of 35,000, is confined to those who are Jains by religion, in the health figures the term Shravak is used loosely to include all Hindu traders, except Bhattias and Lohanas. The fact is, that the total population represented by Shravaks in the health returns is probably nearer 50,000 than 35,000."

Dock labourers are supposed to have suffered inordinately, because they are often very exhausted at the end of their days work. They get their meals irregularly, frequently have no rooms and sleep in passages or verandahs in bad localities. When attacked they often stick to their work till completely exhausted.

Hindus of all castes from the N.W. Provinces and Oudh also suffered heavily, and in their case the cause assigned is their poor food and their residences in affected localities, often to guard houses deserted by their occupants through fear of plague.

Mahomedans and Parsees suffered from their dislike of going to hospital. A number of sick Parsees were secretly removed from affected to non-affected quarters of the town, and thus were in motion what the report calls a "Parsee Plague Current." However, the leaders of the community atoned for the malpractices of their less enlightened brethren

by the energy with which they built and equipped hospitals and health camps. As to the Christian community, they were also severe sufferers in both epidemics. The Committee observe that one main source of infection amongst the Christians came through the nurses and other persons in the houses of rich Parsees. They contracted plague in the discharge of their duties, and were sent to their own homes to die. But this was not the whole source of infection among the Christian community, for, says the report, "when human *vahans* or carriers were guarded against, plague rode in on a sick rat." The Committee offer a tribute of respect and admiration to the conduct of the Christian community during both epidemics. It is remarked that "whenever the patient, and however well and dearly cared for at home, if the case was declared plague or suspicious, wife, daughter, or son were voluntarily sent to hospital, and all arrangements to disinfect were attended to without delay." It would have been well for Bombay if the example of the Christians had been more widely imitated.

PROGRESS OF PLAGUE IN BOMBAY.

THE number of deaths recorded from Plague in Bombay city for the week ending 18th October was 150, against 240 for the week ending 11th October.

This is a decrease of 90; while the total mortality has fallen from 990 to 828, a decrease of 162.

This sudden improvement in the general health is as pleasing as it is unexpected and its continuance will be eagerly watched for. For the week ending 28th October the deaths fell to 104.

The "Times of India" gives a very credible explanation of this remarkable falling off in the plague mortality, it is as follows:—

"In searching for a sufficient explanation of how a spreading plague has received a sudden check, we are met by the difficulty that spreading plagues remain uninfluenced by suddenly applied sanitary measures, or by sudden climatic changes, and the conclusion has been pretty generally arrived at that spreading plagues are never checked or 'stamped out.' But the difficulty of finding an explanation as to how or why a plague suddenly showed a decline is removed by considering the people apart from the plague. The plague may be holding its grounds when, of course, the mortality would increase during the period of spread; but the people may change their relation to the plague, and if this change is extensively made, the mortality may be diminished in consequence of such a change. This change and its consequences may be illustrated by a reference to what has actually occurred in Bombay during the last three or four weeks. It is in this period that the rains ceased, and this cessation has been followed by hot and very close weather, especially at nights. As soon as the rains ceased, the labouring population, amongst whom the plague has chiefly prevailed, resumed their usual habit of sleeping on the roads and on open spaces outside the houses. At present, nearly all available places near the houses of the labouring poor are largely filled with nocturnal sleepers. A ramble one night this week through the labouring quarter of the town showed that this well-known practice was once more in full swing. We are assured that not less than 100,000 persons were sleeping out that night, some on the public roads, some on open spaces near the houses, and upon open verandahs. A large portion of the labouring poor had thus suddenly changed their position with reference to the plague, for whereas during the rains the worst indoors in the houses they now sleep in the open. The infection being in the houses, and nowhere else, the people who slept in the open

in the blood for signs of general toxemia. The only case occurred in trying it in leucemia, in which case it was found to have caused the reaction. The blood was then treated for the reaction; 5 ccm. of blood were taken from a vein of a diabetic patient, and separated from the plasma by a centrifuge; the corpuscles were then washed with distilled salt solution until the washings showed no trace of sugar; the typical BAXTER reaction was then obtained with the blood corpuscles. It was also found that oxymal blood treated with a weak acid gave the reaction.—*Brit. Med. Jour.*

Extract of Suprarenal as a Stimulant in Dangerous Chloroform Narcosis.

FALLING the subject of a series of observations made upon dogs by Dr. F. A. MAGKROVSKY who concludes that compared with the procedures of BUKHLEER, LABORDH and KOWICZ, intravenous injections of even 15 to 30 grains of a 1 per cent. solution of suprarenal extract are (1) preferable on account of its more rapid action and (3) capability of saving the life of extremely chloroform narcosed dogs by (3) exercising a marked influence upon the respiration, the blood pressure and the tone of the heart muscles but (4) it is wise to keep a freshly prepared and sterilized solution of suprarenal extract ready to hand to controvert any sudden collapse during chloroform narcosis and (5) but the best results (in cases of imminent death due to chloroform are obtained by combining the intravenous injections of suprarenal extract with massage of the cardiac region and the subcutaneous injection of physiological salt solution.—*N. Y. Med. Jour.*

Causes of Subnormal Temperature.

DR. JAMESON sums up the causes of this condition as follows: 1. After the direct withdrawal of heat from the body, as in cases of exposure of unconscious or drunken persons in a very cold atmosphere, or after immersion in very cold water. 2. After the loss of great quantities of fluids from the body, as in severe diarrhoea, enteritis, cholera, or profuse hemorrhage. 3. In conditions of cachexia and inanition such as cancer of various parts of the alimentary canal, severe forms of diabetes, pernicious anemia; during convalescence from febrile affections; and in many chronic mental diseases. 4. In grave circulatory disturbances, as in cardiac failure. 5. In various diseases of the central nervous system, in tuberculous meningitis, at the onset of cerebral hemorrhage and embolism, in some cases of brain tumor, and in general paralysis of the insane. 6. After irritation of sensory nerves, as in intestinal strangulation, in renal and gall-stone colic, in internal perforation of the intestine, etc., and after surgical operations. 7. In skin affections involving large areas, such as scleroderma and extensive burns. 8. After fevers, when the temperature may long remain subnormal, or in the course of certain fevers, as in pyæmia. 9. In cases of poisoning by phosphorus, strychnine, morphine, carbolic acid, and in alcoholic intoxication; also in the auto-intoxication of uræmia and in diabetic coma. In some healthy persons subnormal temperatures are occasionally observed without any apparent cause.—*N. Y. Med. Rev.*

Cure of Werthof's Purpura Hemorrhagica by Ovide Bone Marrow.

THE *Bull. Soc. de Therap.*, notes a case recorded by Voinitch and epitomized in *Vratcha*. A girl, eight years old, was suddenly attacked by fever (38 to 39 C.), anemia, and articular pains. The painful joints became covered with purpuric lesions, which extended to the internal aspect of the lower extremities, and the dorsal aspect of the elbow and carpal joints. Then foetid bloody diarrhoea set in; the belly was distended and the seat of severe colic.

Chamel, quinine, and antipyrin were given; ice was applied to the abdomen and subcutaneous injections and ergot and atropine of soda were administered. As the gravity of the case increased, calf bone marrow was administered to the extent of two tablespoonfuls daily.

Three days after a steady improvement set in. The marrow was prepared by trituration with boiled water, cooled to ordinary temperature, filtered, and some milk added to make it more agreeable.

Preparation for Emergency Intubation.

These intubation practices on a patient, a foreigner, and a child are essential to correct procedure in intubation, says Dr. J. J. Woods who summarizes the following points: (1) Lie the epiglottis against the tongue by passing the left fore-finger, protected by stretching back to the pharynx and drawing it forward between the epiglottis. (2) Lay the handle of the introducer, touch the chest where the tube is put into the mouth then raise the handle till the tube touches the left fore-finger, which is then slipped behind the tube and the handle raised to a right angle while the tube passes into the larynx. (3) Place finger on top of the tube as the obturator is withdrawn. (4) Do not let the child sit up and if very young, stiffen the shoulders with padding and strapping. (5) Feed with the head lying back over the pillow. (6) The retention of the silk in the tube, is most necessary so that the tube may be quickly removed should it become blocked with membrane or in case of extreme dyspnoea. (7) If the silk has been bitten through invert the child and express the tube by pressure from outside. (8) Remove tube in two or three days and re-intubate if necessary. (9) The steam tent is useful in dyspnoea after removing the tube.—*Amer. Gyn. and Obstet. Jour.*

Successful Ovariectomy in a child four Months old.

A breast-fed girl, aged 4 months only was placed under the care of Dr. OANN for an enormously distended and very tense abdomen which measuring 20.5 inches in girth (at a point 2 inches above the umbilicus) and 10.5 inches from symphysis pubis to xiphisternum tip was dull to percussion, but gave a well-marked thrill. The urine was normal and legs not cedematous. Abdominal section was performed and as soon as the peritoneal cavity was opened a small quantity of fluid escaped and a smooth shiny bluish colored ovarian cyst, was seen with numerous blood vessels ramifying over its thick walls. To enable the circulation to adopt itself to the altered abdominal condition 40 oz. of a clear yellow fluid were slowly drawn off from the cyst which was then removed from the abdomen, emptied of its remaining 19 oz. of fluid and separated from its pedicle which was transfixed and ligated with file silk, and after division dropped back into the abdomen. The child was a little collapsed after the operation, but soon rallied and made an uneventful recovery in 14 days.—*B.M.J.*

Treatment of Sarcoma and Carcinoma by Injections of mixed Toxins.

In a paper recently read before the Harveian Society of London, Dr. MARSHALL MONTILLOX mentioned that many sarcomata that were operable, even after repeated operations, had absolutely and entirely disappeared when injected with Dr. COLEBY'S mixed toxins (1 minims gradually raised to 8 minims for each hypoderm) under which lupus, keloid, syphilitic deposits, carcinomata and other such growths have also disappeared rapidly and permanently its matter whether the toxins were injected directly into the growths or into some distant part of the body. The effect is most striking in rapidly increasing sarcomata, slowly growing ones appear to have much more resistance. The toxins are useless unless the cultures are taken from a virulent case of erysipelas or are made virulent by passing the streptococcus through rabbits. They can sometimes act by starting inflammation but by irritating and promoting so intensely; rapid form of fatty degeneration (and absorption), something like that of yellow atrophy of the liver. If inflammation and

impressed by the tampon. According to E. S. GARRISON, TWENTY, ST. LOUIS, P.R.C.P.I. the best material to use is sterilized cotton wool treated with a weak antiseptic solution and the proper way to apply the tampon is:—(1) Throw many pledgets of cotton wool as large as a closed fist into a basin containing some weak antiseptic solution and let them soak while, (2) the patient is brought to the edge of the bed, (3) placed on her left side, (4) her vagina and vulva rendered aseptic and (5) her bladder emptied. She is now ready for the packing which is done by taking, (6) the pieces of cotton wool—one by one—squeezed out to almost dryness and compressed into as small a compass as possible and so inserting them without the aid of a speculum—that the cervix is surrounded by pledgets before the os is covered. Each piece is packed as tight as possible and (7) then the vagina is filled with cotton wool pledgets to its utmost capacity down to the urethra, (8) a diaper is placed between the thighs and a tight abdominal binder completes the operation.—*Brit. Med. Jour.*

Diagnostic Value of the Abdominal Reflexes in Gynecology.

BODOW believes from examination of 800 cases in the Budapest Hospital, that the condition of the abdominal reflexes may be of use to the gynecologist, as well as to the neurologist. To be of any diagnostic value, the reflexes must be distinctly weaker on one side than on the other, or completely absent on one side as in many persons presumably healthy they cannot be elicited. BODOW found that the reflexes were most easily brought out in young nulliparae, with thin abdominal walls. He examined the reflexes in several cases of pelvic cellulitis and peritonitis, with a view of differentiating them, and although he admits the almost constant combination of the two conditions, yet he believes the results obtained might assist in the prognosis and treatment to be applied.

In pelvic cellulitis he found the abdominal reflexes unaffected; whilst in pelvic peritonitis they were lost or greatly weakened. In bringing out the reflexes in very acute cases, it was found to produce sudden pain on the affected side. This BODOL attributes to slight imperceptible muscular contractions, sufficient to cause slight displacement of the peritoneum with consequent pain.

BODON raises the question of the existence of a reflex in the female, corresponding to the cremasteric reflex. Reference is made to the work of GUNDEL, who regards the inguinal reflex as equivalent to the cremasteric reflex. BODON bases his observations from the cremaster muscle in the male corresponding to the round ligament in the female, both receiving fibres from the internal oblique muscle; a forward movement of the uterus towards the contracting round ligament corresponding to the upward movement of the testicle in the cremasteric reflex.

In order, if possible, to bring this out, BODON placed one finger against the anterior fornix, so to as note any movement of the fundus, and with the other hand irritated the skin on the inner surface of the thigh—result negative. He then introduced a sound into the uterus, and irritated the skin of both thighs at the same time, to ascertain any forward movement of the uterus. The result was, that the sound moved in a backward direction; showing, BODON thinks, that the fundus had jerked forwards. He regards the subject worth further observation.—*Edin. Med. Jour.*

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

Gastric Secretion.

PAWLOW notes that the whole process of gastric secretion which (1) beginning five to six minutes after the commencement of a meal and gradually weakening down after lasting for four to five hours, is (2) purely reflex from beginning to end, (3) and most of the secretory fibres reach the glands by the vagus, (4) whose fibres must be intact for a fictitious meal to cause a really active secretion. (5) That the influence of food on the pharyngeal mucous membrane is psychic, not mechanical and that it varies with the kind of food ingested, was proved by GAZOTSKI, LOBASSOFF and others adopting PAWLOW and NEROKI's modification of HEIDENHAIN's mode of *unknowns* to the animal passing certain foods through an artificial gastric fistula, (6) where they remained undigested unless a psychic influence was brought to bear. (7) Gastric juice, which appears to be of two sorts, the (8) pneumogastric and (9) the non-pneumogastric secretion, is (10) not of uniform composition in the same animal and as (11) the mucosa adapts itself to the food present, since (12) each kind of food requires a special kind of secretion differing in quantity, quality, acidity, activity and length of latent period, the (13) vagus contains fibres as well for the mucous as for the gastric juice glands and foods may be divided into (14) those which require the psychic influence of the appetite for their digestion, and (15) those that can cause secretion of gastric juice without it, but (16) in the latter case secretion occurs later, lasts longer and is lower in quantity, acidity and activity than the psychic juice.—*Brit. Med. Jour.*

Normal Size and Location of Stomach.

A. L. BENEDICT, A.M., M.D., Professor of Physiology and Digestive Diseases, Dental Department, University of Buffalo, calls attention to the fact, that it is difficult to find exact statements in text books as to the *normal* size and location of the stomach; and it is by no means uncommon to find physicians making the diagnosis of gastric dilatation who are not able to state either just how large the stomach is, or how large it should be. Speaking from some six or seven hundred examinations by auscultatory percussion of normal and abnormal stomachs—accurate records of about 200 have been preserved—it may be stated that the area of the normal, empty, adult stomach, is an ellipse, whose major axis is inclined at about 45° from the horizontal, whose lowest point is about an inch above the umbilicus, and half way between the middle and axillary lines, and whose right curve does not pass appreciably to the right of the median line, though the stomach itself does so. The area of the normal, full stomach reaches quite to, or perhaps half an inch to the right of the median line, and the lowest point is not less than half an inch above the umbilical equator. Large, fleshy women often have a descent of the abdominal wall, so that the stomach, though by no means small, is two or three inches above the umbilicus. In children, the stomach is relatively larger than in adults, being absolutely of about the same size after the age of fourteen. Thus the adolescent stomach is not more than a quarter of an inch above the umbilical equator, and the stomach of a child of two or three years reaches fully to this line.—*Virginia Semi-Monthly.*

Beginnings of Mental Life.

THIS was the title of a brilliant address delivered by professor DOKAEN at the annual meeting of the Budapest Hospital Association. He started with an interesting description of the faculties of some of the lower forms of animal life and concluded that mental life is an evolved form of cell activity.

He then reviewed the address of Dr. Brown at the last annual meeting of the British Medical Association at Montreal, in which it was stated that mental disorders are to be attributed to syphilis. Professor DONATIE is of opinion that the principal cause of the spread of mental disorders in the present day is first to be sought in the very hard struggle for life and secondly, but in no lesser degree, to the spread of syphilis and alcoholism. It is very interesting to note that he tried to prove that mental faculties taken grossly are the same in the savage as in the civilised man and that it is principally the absence of mental exercise and the different mode of living which explain the lower mental standard of the former.—*Lancet*.

Venom J. Naja Haje.

BETTER known as Cleopatra's asp is so fatal that in Ceylon alone some 20,000 persons annually succumb to it. ARMSTRONG, CALMETTE, REICHAERT, WALL, WEIR MITCHELL and others who tested it declare that the venom is chemically identical with the poison of Naja Tripudians and when dried appears as transparent scales easily soluble in water, very slightly so in alcohol, chloroform or ether and its aqueous solution which is neutral to litmus paper, has an unpleasant odor, but GRABIANI (*Bif. Med.*) who made a physiological study of it finds that it has a considerable affinity for the kidneys and liver, and that extremely minute doses proved rapidly fatal to guinea pigs, who a few seconds after injection became paralysed in the hind limbs, foamed at the mouth, made violent attempts to vomit, respiratory embarrassment soon follows together with vomiting and abundant secretion of frothy saliva and finally death from asphyxia. Immediate autopsy discloses heart still feebly beating other lungs pallid and the blood in the organs very dark. The brain and cord with their coverings are anemic and there are effusions into the muscular tissues while the red blood corpuscles are in great measure broken down, but the central nervous system shows no particular changes. The kidneys are very hyperemic with marked degeneration of the epithelium lining the glomeruli and convoluted tubes. The liver also is hyperemic with partial necrosis of its cells.—*Brit. Med. Jour.*

Biology of the Tubercle Bacillus.

MARPMANN claims to have opened up a new point of view in bacteriological pathology by his researches on the growth of the tubercle bacillus. This has long been known to secrete a cellulose capsule, which is a characteristic of aerobic microbes, whereas those which are anaerobic are distinguished by the formation of volatile gases such as marsh gas, sulphuretted hydrogen, phosphoretted hydrogen, and ammonia. The author finds that tubercle bacilli grow readily on a new medium, consisting of crude lecithin rendered germ free by repeated warming to 50 C. At first only traces of volatile gases are given off, but after five or six days, if the access of air is prevented, the presence of phosphoretted hydrogen can be demonstrated by the contained gases blackening paper impregnated with silver but not lead. MARPMANN concludes that the tubercle bacillus is capably anaerobic, and can give rise to reduction as well as oxidation products. The formation of phosphoretted hydrogen is much more marked in the case of cholera bacillus, and it is suggested that the symptoms of cholera intoxication may be due to that gas. Similarly it is possible that this and other gases may be the causes of the symptoms of other bacterial infections, if this is the cause, treatment should aim at neutralising them as well as at increasing the resistance of the tissues to them. It is this new suggestion which the author considers may lead to most important results.—*Brit. Med. Jour.*

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Aspects of Towns and Dwellings.

AT the request of the Organizing Committee of the International Congress of Hygiene and Demography held at Buda-Pesth, 1894, Professor CORFIELD prepared a series of resolutions relating to the sanitary conditions of towns and dwellings. These resolutions were submitted to a special joint meeting of three of the Sections of the Congress, and were the subject of a very animated debate. They were ultimately referred to an International Committee consisting of the following members: Professor CORFIELD, London (proposer); Dr. PISTON, Berlin (secondor); HERR ANDREAS MEYER, Chief Engineer of Hamburg, M. G. REICHMANN, Ingenieur-en-Chef des Ponts et Chaussées, Paris; Professor FODOR Buda-Pesth, Mr. ARTHUR DARRM, Architect, London; HERR BRUNER, Chief Architect, Vienna; HERR LINDLEY, Engineer, Frankfurt-on-Maine; and Dr A. J. MARTIN, Member of the Consultative Committee of Public Hygiene of France.

The resolutions were revised by this Committee and were submitted to the International Congress recently held at Madrid, where they were adopted as resolutions of the Congress. They may be taken to represent the maximum amount of agreement possible at the present moment among sanitarians of different European countries. They are as follows:—

1. That the general health of the population is improved and the spread of diseases prevented in town and dwellings by the immediate removal of all foul matters, and by a copious supply of pure water.
2. That the paving of streets should be smooth, and as far as practicable impervious, to facilitate cleansing and also to prevent contamination of the subsoil.
3. Special measures should be taken in the construction of houses to prevent the access of ground air and moisture to the floors and walls.
4. House drains should be arranged so as to avoid stagnation of their contents, and to secure a rapid flow to the street sewer. They should be impervious to liquids and gases, freely and continuously ventilated, and provided with siphon traps to prevent the access of foul air to the houses.
5. The public sewers should be so constructed as to ensure the rapid and uninterrupted flow of the sewage to their outlets. They should always be freely ventilated.
6. The streets should be as wide as possible in proportion to the height of the houses, this proportion should be fixed in each locality, regard being had to local circumstances and to climate. Every inhabited building should be well-lighted throughout its whole depth, and arranged so as to have an access of air from at least two sides.
7. Special regulations should be made in each locality by the public authorities with the view of enforcing the practical application of the principles herein laid down.

Governments and municipalities should resolutely and energetically carry out the preceding recommendations, especially those concerning the healthiness of dwellings.—*Brit. Med. Jour.*

Sterilised Water.

IT betrays an incomprehensible ignorance on the part of the public in respect alike of scientific and of industrial matters that tourists and others should imagine that when travelling in foreign countries or residing in India they can avoid the risk of infection with cholera or typhoid by restricting themselves to the so-called aerated and mineral waters, as if the addition of a few grains per gallon of carbonate of soda and the impregnation of a contaminated water

with carbolic dioxide could have any appreciable influence on the pathogenic microbes that may be present. PAOR, BRESCIANO, of Milan in an able and popularly-written pamphlet urges the boiling of all water open to the least shade of suspicion as the only trustworthy and rational procedure. The addition of chemicals in quantities compatible with potability he shows to be utterly futile, while the great majority of filters are delusive, and even the few effective forms, as PASTEUR'S and the BAKERSFIELD, need attention; whereas boiling cannot fail to destroy every germ, whether pathogenic or innocuous. He combats the prejudice against boiled water as a beverage, maintaining that the "taste" frequently complained of is really caused by the state of the kettle or other vessel in which it has been boiled, as it can scarcely be due to the escape of the CO_2 or dissolved air, of which water from wells of great depth often contains very little which is rapidly restored by exposure or by agitation. At any rate, the balance is so overwhelmingly in favour of the practice of boiling all water (and milk), of the purity of which one is not absolutely certain, that it should never be neglected save in the case of deep wells or water-works under unimpeachable management.—*Practitioner*.

Inference from removal of Ovaries.

In some cases injuries are sustained which are of such a nature as will, in themselves, warrant an inference that they will permanently affect the injured person's health, or lessen his or her capacity to labor. But the United States circuit court of appeals declares, in *Western Union Telegraph Company vs. MORRIS*, that it can not say that the injuries inflicted by a surgical operation, which consisted in removing ovaries and Fallopian tubes, were of such a character that a jury was at liberty to infer therefrom that the health of the person upon whom the operation had been performed would be permanently affected, or that her capacity to labor would be thereby impaired. It is just as reasonable to suppose, in the absence of any evidence on the subject, continues the court, that she sustained no loss in either of these respects. On the other hand, the court holds that it was not reversible error to leave the jury to determine whether a telegraph company's failure to properly transmit a message summoning a physician was not the proximate cause of the plaintiff's being subsequently compelled to undergo such a surgical operation, when the physician testified that if he had reached the patient at the time he would have, but for the mistake, he believed that he could have rendered the subsequent surgical operation unnecessary.—*Jour. Amer. Med. Assoc.*

Death from Cocaine.

DR. G. DANFORD THOMAS held an inquest at Paddington on 18th April, on the body of FLORENCE EMIN, the wife of Dr. M. EMIN, of 149 Ledbury Road, Baywater, who died from the effects of poison self-administered. The deceased was occasionally very depressed, and eight months ago, she swallowed a quantity of laudanum from a phial she found in her husband's black bag, assigning no reason for doing so, but telling her husband immediately after the act. Antidotes were applied, and she soon recovered. On the day of her death she informed her husband that she was feeling ill, and producing a small bottle from her pocket (which she had obtained from her husband's bag, as in the previous case), said "I have taken cocaine; go for a doctor." Dr. EMIN said deceased had apparently swallowed half an ounce of a solution of cocaine containing from 40 to 48 gr. of the alkaloid. He hurried off for a doctor, and on his return she was unconscious, and died in about a quarter of an hour. Dr. A. DAVIS, of Cronwall Road, Baywater, who was called in, and had made an autopsy, stated that death was clearly due to cocaine-poisoning. The jury found a verdict of suicide while of unsound mind.—*Chron. and Deng.*

PARALYSIS AND RHODODENDRON.

Diphtheria and Rhododendron.

Dr. ROBERT T. COOPER (*Calif. Jour. of Med.*) calls attention to a peculiar pathogenic symptom of Rhododendron closely resembling a peculiar form of paralysis following that disease and Dr. HAZEN WHITE tells of how unilateral paralysis of the palate so attacked a man 21 days after a severe attack of diphtheria that while drinking some tea he began to cough violently and within 10 minutes died. At the necropsy 1.5 ounce of tea was found in the bronchial tubes as the real cause of death.

Dr. EMMET ST. CROIX uses tincture of Rhododendron to combat the evils of diphtheritic paralysis and veterinary Surgeon COLLING (*Field*) says that some two years back he had to deal with a flock of 150 sheep that were believed to have been poisoned by eating rhododendron leaves. Some 50 or 60 were put under treatment which resulted in the recovery of all but 9. Two of these dying immediately on having a dose of stimulant being given, a *post-mortem* was held which showed that the fluid administered had proceeded the wrong way, reaching the lungs instead of the stomach as these sheep had evidently lost all power of swallowing.—*Brit. Med. Jour.*

Some Therapeutic uses of Olive Oil.

AT the seventh annual meeting of the Association of Military Surgeons of the United States, Dr. M. O. TERRY, Surgeon-General of the National Guard of this State, advocated the treatment of appendicitis with sweet oil. He said he had treated forty-five cases of appendicitis, only two requiring operation; and all recovered. His method is as follows: A cathartic is given at once, together with a "colon or high enema, fomentations with flaxseed poultices and applications of hot sweet oil, the prolonged use of sweet oil taken internally and a poultaceous diet." His choice of cathartic is castor oil one part, with sweet oil two parts. A high injection of one-half to one pint of sweet oil is given, followed by a soap suds enema. Sweet oil is also given internally, a half ounce in a glass of hot water three times per day. This is continued as long as there is tenderness in the region of the appendix.—Dr. O. M. TERRY in *Put Grad*.

Indications for and against the Use of Duboisin.

AFTER an extensive trial of the sulphate of duboisin, SKENE finds that (1) in epilepsy it sometimes relieves and sometimes increases the excitement without lessening the number of spasms; but though (2) it gives excellent results in excitement due to hallucination and delusions and (3) forms an useful sedative in all forms of excitement in chronic insanity it is (4) positively dangerous in melancholia or acute mania and (5) should be limited to physically healthy persons; since (6) it produces reactional excitement and its continued use results in (7) a rapid loss of weight and (8) a tendency to syncope.—*Jour. of Mental Science*.

How to Administer Crocote.

In order to obtain the best results from the use of crocote more attention should be paid to the method of administration. According to a writer in *La Med. Modern*, the best of all the numerous methods suggested is to give the drug by mouth in capsules, each one of which contains $\frac{1}{2}$ grain of pure crocote, emulsified with 1 grain each of cod-liver oil and balsam of tolu. In this manner the disagreeable taste and odor are avoided, while this emulsion is one of which all the ingredients exercise a favorable influence upon the respiratory tract and do not irritate the mucous membrane of the stomach. Many writers have at different times reported

in the dinner-party, or in otherwise in a shop, and, there is no other choice of a doctor.

Now when you come to think of it, these four classes, who have just been shown to be interested in the question, comprise pretty well the whole community; which looks very much as if the *Museocric Memorial* concerned us all. And so it does. It would be a great and regrettable mistake if the lay public, who are the sum total of patients and patients' friends, turned away from the subject with the idea that it is merely a squabble among the doctors, who are proverbially prone to disagree, and that all they (the public) have to do with it is to leave the said doctors to fight it out and settle it among themselves, with the comfortable confidence that a paternal Government will step in to prevent their settling it after the fashion of the Kilbrany Gate, who fought till they had eaten each other up all but the tips of their tails, for of course we must have doctors of some sort. This being so, we shall be doing our readers a service if we offer them a concise explanation of what the question at issue really is, promising that we desire to state it fairly and impartially, but that necessary limits of space forbid our touching upon all the arguments adduced *pro* and *con*.

The *Museocric Memorialists*, then, backed by the Indian Medical Association, respectfully call the attention of Government to (a) the violation of their avowed policy, so stringently applied to the officers of all other Departments of the State, in the case of the Indian Medical Service; and (b) the hardship thereby inflicted (increasing naturally with the increase of the European population, and with the spread of education among the native population), viz., that of the independent qualified medical profession in India. The Government policy in question which is approved and its extension recommended, is that which prohibits State-paid officials, responsible for important duties, from engaging in private remunerative occupation. It is admitted that exception in favour of the officers of the I. M. S. may have been justifiable, perhaps even necessary, a couple of generations ago; but it is pointed out that the conditions prevailing then have undergone important modification since. The hardship complained of is that, while qualified doctors, both Anglo-Indian and Native, are being trained in large numbers, and the social development of the large centres of population invites private professional enterprise, the independent medical practitioner finds himself confronted by unfair competition in the shape of the state-salaried official surgeons enjoying unlimited freedom of private practice. This unfair competition involves both remuneration—because these officials, receiving a salary proportionate to their rank in the service, and in the case of senior officers a very handsome salary, are in a position to “under-sell” their less favoured colleagues in private practice; and also professional reputation and standing—because the same officials, being specially accredited by the fate of their State appointment, enjoy an artificial prestige at the expense of their independent colleagues, who may nevertheless well be their equals, and conceivably even their superiors in academic qualification, practical experience, or professional skill. This in brief is the case for the independent members of the medical profession. On behalf of the public it is urged that medical

officers, whose time and energies are already consumed by the increasingly and important duties for which they receive their official emoluments, cannot, by the operation of the common laws of time and space and of physical and mental endurance, which limit the activities of us all, be in a position to practise efficiently, in addition to these, the responsible duties of a more or less large private and family practice. In view of the facts it is respectfully submitted that the time has now arrived for withdrawing the privilege of private practice from state-paid doctors in large cities and hill stations and for thus throwing open a fair field and no favour to medical enterprise in India as elsewhere. This is proposed primarily in the interests of the independent medical profession and of the public but also partly in that of the, at present, greatly over-worked civil surgeon himself; and it is characteristic of the reasonableness and moderation of the proposed reform that it is stipulated, also in the combined interest of all three parties, that the civil surgeon should still retain the right of consultation with private practitioners in family and general practice.

On the other side, in behalf of the civil surgeon whose special privileges are directly attacked, will be urged all the arguments that always *em* urged in support of monopolies, vested interests, class privileges, *et hoc genus omne*, when the time comes to each in turn for re-adjustment; and they will be answered, now as they have been answered over and over again, ever since the days began for the overhauling of these venerable institutions. In behalf of the also highly privileged class of State officials non-medical, for whose particular benefit the civil surgeon is so liberally endowed, it is argued loudly that they and their families have pre-emptive right to the very best medical attendance that can be provided for them gratis, or nearly gratis, and that if the door were opened to professional Goths and Vandals in the persons of independent practitioners, this enviable privilege would be lost to them. Apart from the protean plea for class-privilege which re-appears in this argument, it is intrinsically funny in its naive taking for granted that the civil surgeon always and everywhere is the very best man—he and nobody else, and not much less so in its “convenient disrememberment” that even the very best man is apt to be just a little better for being handed over to the wholesome discipline of competition. The proverbial plain man will be inclined shrewdly to suspect that the best men are most likely to come to the top when no one is either held down or propped up by artificial means.

Last of all, but by no means least, what is to be said for the Government to whose lot it must ultimately fall to devise means for rectifying the abuse, doing justice all round, and satisfying all complaints, and whose hands are already so full? Fair is fair all round; and honesty compels the admission that the settlement will involve some practical difficulties. The withdrawal of permission for private practice from a certain number of civil surgeons, and these as a rule the senior and most capable and experienced men, will certainly evoke the outcry that Government has broken faith with medical officers who entered the service on the understanding that certain plans were to be had. The abolition of the large Civil Surgeoncies, which has been suggested as an alternative

profession or trade for which they may have qualified. I see no reason why the Judge, who is a barrister, may not close his Court whenever he has a case in the Magistrate's Court; to go and plead there; I see no reason why the Superintendent of Police may not utilise his acute powers of Sherlock Holmesism by opening up a private detective agency for the prosecution of Mussoorie divorcees; I see no reason why the District Engineer may not build Kapurthala's chateau; I see no reason why the Depot Commandant at Landour or his Staff Officer may not organise a ladies' shooting gallery, charging a gold mohur entrance fee; or Sir JAMES WESTLAND, able financier as he is, open a large banking corporation at Calcutta, and I certainly see no reason why Mr. SECRETARY MILLER may not edit the Allahabad paper. The public have a decided grievance in being deprived of the services and talents of these excellent officers.

Yours &c., L.R.O.P. & S. Edin.

ALLAHABAD, 20th July 1898.

MALTHUSIANISM.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Your contemporary, *The Bengal Times*, has found fault with your arguments against Malthusianism, although he admits that "Malthusianism is in direct opposition to Divine teaching, and is so great an offence, as to have incurred, for its first disciple, no less penalty than that of death. Not only, then, does nature's instinct revolt against an act that frustrates its ordained end, but it may incur a visitation of divine wrath dreadful in its consequences. You abstained purposely and for obvious reasons from introducing religious or theological considerations, though you are convinced, that purely human philosophy is not, as a rule, a sufficient deterrent from moral evil. I am bound to say that your contemporary has not a single argument against Malthusianism, except this reference to the Bible; and the objections which he thinks fit to make against your arguments, would in their logical conclusions, militate against his own position "that nature's instinct revolts against an act that frustrates its ordained end." Why should nature's instincts revolt, if nature's propensities and inclinations are (as your contemporary holds) the proximate determinants of human actions? You maintain probably, in spite of the confident assertion of your contemporary that you are evidently (!) off your perch and that you have somehow missed the point, that propensities and inclinations, as such, that is to say, independent from the control of reason, are not the proximate determinants of human actions, and you must stoutly deny that the human will (you used the words "rational will") is subordinate to impulsion. According to your contemporary "human will is merely a subordinate mechanism to mental, moral, and sometimes even to physical impulsion." There is a denial of free will, if ever there was one. Man feels a "mental" impulsion to murmur against God, because he considers God the cause of his child's death,—or he feels a "moral" impulsion to defend his honor by a duel, which his judgment condemns; or he has a "physical impulsion to get drunk;—why, he cannot help himself, for his will is but a sub-

ordinate mechanism" to these impulsions. I confess I do not see why, on the showing of your contemporary, the will should only "sometimes" be subordinate to physical impulsion, for the latter is generally far stronger than mental and moral impulses. The fact is you both are not agreed on your terms. You hold intelligence and will to be supersensual attributes, and therefore you spoke of the "rational" will. The office of the intellect is to pursue truth, of the will to embrace goodness. The former may err in its pursuit, the latter may refuse to accept the true good and agree to what is only apparently so; for example, physical satisfaction in the presence of its moral condemnation. But intelligence and will are both above sense as attributes of the soul whereas you thought you had made it clear that you understood by "propensities and inclinations" those blind forces of the sensual "appetites," seeking the immediate satisfaction of the corporal organs, without reference to higher or more remote good. Surely these inclinations must be refrained by the will, and their use dictated by reason.

Yours &c., A. READER.

SOUTH INDIA, 16th July 1898.

WHO IS MR. HAEGERT? IS HE A QUALIFIED MEDICAL MAN.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Enclosed you will find a clipping from the *Indian Witness* of 8th July which seems to have been written to advertise Mr. HAEGERT's wonderful (?) skill!

No doubt the medical profession throughout India, will be glad to know of the existence of such a medical monstrosity in their midst. Should any of the brethren come across a case which they cannot manage, let them write the name and age of the patient on a ten-rupee note and send to Mr. HAEGERT's address. He will in return send a bottle of "Panacea for all diseases."

Whatever Mr. HAEGERT's motives are, no doubt they are good, it seems to me that a man professing to be a follower of the "meek and lowly one" should be a little more reserved in the use of the "ego" and in making assertions that it is hard for an intelligent person to believe.

Yours &c., W. W. ASKE.

M. E. MISSION, PAURI, GARHWAL, 18th July 1898.

Extract from *Indian Witness*, 8th July 1898.

"A REAL JUNGLE WALLAH."

"DURING the year I had the privilege to attend medically the Missionaries and their families of nine different Societies—English, Scotch, Americans and Germans. Some wrote to me from 100 miles to get medical advice. This shows wonderful confidence. They passed by scores of Doctors to come to MR. A Lady of the U. M. S. wrote: "I can never thank you sufficiently for the good your medicines did me." A Baptist Missionary had his daughter cured. I CURED her when others could not; and yet this sinner never wrote to thank me. No doubt he often thanked God for the cure. A real American said that "my medicines had done him a mighty lot of good." A Canadian wished to send my fee by instalments. I replied: "You will have to work it off on your knees by praying for the success of Christ's Kingdom in these jungles." A Scotchman thinks that our prescriptions are "better than what you can get anywhere else," and recommends them right and left for eighteen years, etc., etc. However, when "The Professor" comes under my treatment, I shall give him a dose of medicine to make him jump for joy.

The poor I attend daily. The last patient came half-an-hour ago. However a few doctors, several engineers, and

some of the tip top people were also attended medically by me during the year. A rich lady, with about Rs. 800,000 in the bank, and a great sufferer, whom *twelve good doctors* had failed to benefit, in India and England, appealed to me. I cured her as if it was child's play. Every farthing of my fee has gone into the mission box. My master keeps me with food and clothes, and keeps me alive; so I cheerfully serve Him. Beside He says: "Be thou faithful unto death, and I will give thee the crown." Praise Him.

Our 1800 Christians live in 120 villages. There is every reason to thank God and to take courage. If you get to heaven before me, then look out for the Jungle Wallah, with 10,000 at his back. Praise ye the Lord. We will all shout, when we get up there. Just now I am hard up for Rs. 500 to help the poor things that come daily asking for seed, food, and oxen to plough their fields. Best look into your banking account and see whether you cannot send us a good cheque. All things are yours, but do not forget that you belong to Christ."

Yours &c., A. HASEGRT, L.M."

Bethel, via Jantara, 25th June 1898.

(We would like Mr. Hasegert to tell us what the letters L.M. signify to him. To medical men and women they signify the possession of a University degree (Irish) or a diploma in midwifery. What school of medicine does Mr. Hasegert hail from? We fail to find his name on any medical register.—ED., L.M.B.)

—:—

PROMOTION UNLAWFULLY DELAYED.

TO THE EDITOR, "INDIAN MEDICAL RECORD"

SIR,—Would you kindly give the following grievance a place in an early issue of your esteemed paper, in the hope that it may catch the eye of some one who has it in his power to alter the lax state of things which causes a great deal of dissatisfaction and grumbling at present in the Sub-Medical Department.

It appears to have been the custom for years to fill up vacancies for promotion twice a year, lately this has not been done, I believe that one vacancy, caused by the death of a first class Assistant Surgeon in June 1897, has not yet been filled up and besides this old standing one there are a large number of others which have occurred since. Anxious eyes have been scanning each gazette as it has appeared up to time; but their hopes and expectations have been a clear waste of anxiety and patience. It seems unaccountable to me why it is necessary to keep things so far in the back ground, it is not because anything is gained or saved thereby, for the promotions carry with them back pay up to the date when the vacancies occurred.

This department would have some thing to be thankful for if those in office, who see to these things, could put forward the promotions every quarter, that is, every 3 months. To us there would then be some meaning in the announcement with which each issue of the Indian Army List comes out, viz., "corrected up to the 30th—1898." If any one thinks that in looking into this publication at present he will find it up-to-date he will soon see he is mistaken, if he has kept any notes of men who have gone off, or gone out within the last 6 or 8 months.

In the Commissariat, the miscellaneous, and the Ordnance Departments, the way they manage this business is an example to ours, but I suppose this is owing, a great deal, to the fact that the clerks who have to see to this are themselves on the same list and have, so far a personal interest in the matter that they expect some day to see their own names nearing the top of the roll.

If more regularity in putting forward the promotions for publication can be brought about by any means, I am sure the whole service will feel under a debt of gratitude to any one who will help to do so.

Yours &c., A. JUNIOR.

20th July 1898.

ON BEHALF OF EUROPEAN AND INDIAN LEPROS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I would again press the needs of this Asylum on your charity, as our daily requirement of food alone is hard to meet. Such a charitable institution must appeal to every one who has ever seen the helpless condition of the leper. By the repelling nature of the disease he is cut off from friends, by its suffering he is cut off from any share in their business which supports them; for sanitary reasons he is excluded from any work for self-support, so he becomes of necessity an object of charity and pity, for even in well-to-do families the leper is an outcast.

The establishing of Asylums is to secure the public against the pernicious influence of roaming lepers. For these reasons, I have boldness in urging yet again our ever recurring needs on the public who have here-tofore helped us so generously and to whom our thanks are due.

At present there are two Europeans in this Asylum and nearly one hundred Indian lepers. Friends help us with your means. Small sums under rupees three are welcome and to save cost, can be sent in postage stamps.

Every year a Report with "balance sheet" is published and sent to subscribers and to others who may ask for the same.

Your donation may be paid into the "Alliance Bank of Simla, Head Office," to be credited to the "Sabathu Leper Asylum Fund," or sent direct to the Superintendent.

Yours &c., M. B. CARLETON, M.D.,

Superintendent, Leper Asylum.

SABATHU, 21st July 1898.

—:—

DR. MATHEW DIAS OF HYDERABAD.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—There passed away, at Karachi, on the 5th of this month, a medical practitioner, MATHEW DIAS, deeply regretted by a large circle of friends and relations and an immense clientele. The town of Hyderabad, Sind, which was the field of his labours has lost in him a man who, for his devotion to his patients and his love and charity for the suffering poor, had deserved well of one and all. His name corrupted into "Mathoo" was a household word in Sindhi homes and will remain so for a long, long time. In his own quiet and unostentatious way he rendered such good service to suffering humanity that his death is a real calamity to the town. For 20 years Mr. DIAS bore alone with courage and patience the burden and strain of his heavy work and to this circumstance must be attributed the sudden breakdown and snapping of the thread of life while yet in the prime of manhood. He was only 46 at the time of his death. It is a pity, that a life as useful as his was, should have been cut short so prematurely, for it has deprived his large family of its only support, and his patients, who could be counted by thousands, of their best friend and healer. But the good are always called away first.

Yours &c., A GRATEFUL PATIENT AND FRIEND.

SHOLAPUR, 25th July 1898.

CHYLO-SEROUS URINE.

To THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Will you or any of your numerous readers kindly suggest a treatment for the case of a Parsee widow, middle-aged, mother of two children, who has been suffering from diabetes for some time past and whose urine has latterly been chylo-serous. I have given Gallic Acid, Tincture of Iron, &c., without success. Can a reader of the *Record* suggest anything else, likely to do good, and oblige.

Yours &c., ALABIC.

(Try good daily doses of sulphate of magnesia and full doses of quinine morning and evening.—ED., I. M. R.)

Book Reviews.

OUTLINES OF MEDICAL JURISPRUDENCE FOR INDIA.

(FOURTH EDITION, 1898.)

BY I. D. B. GIBBLE M.C.S., & PATRICK HEHIR, M.D., F.R.S. & F.R.C.S., Edin.

Surgeon-Major, I. M. S. and C.

(Publishers: HIGGINBOTHAM Co. Madras.)

THAT a work such as "GIBBLE, & HEHIR'S JURISPRUDENCE" was needed and is needed in India is proved by the self-asserting fact that this work has passed rapidly through four editions in a few years. It covers the whole range of practical Forensic Medicine as it presents itself to the practitioner in India, and as a standard text-book for this country, it stands second to none.

INTRODUCTION TO CHEMICAL METHODS OF CLINICAL DIAGNOSIS.

BY DR. H. TAPPENIER.

Translated from the German Edition with an Appendix on Micro-biological methods of diagnosis by Edmond J. McWeney, M.D.

(Publishers: LONGMANS GREEN & Co., pp. 152.)

In this little work the student is provided with a handy guide to the simpler chemical and biological manipulations required in the diagnosis of disease, selecting, as it does, only methods of proved efficiency. In a small compass much practical information is compressed, and a succinct account given of the more useful modern diagnostic procedures clinical, and biological.

INFLUENZA, WITH SPECIAL REFERENCE TO SOME PECULIAR SYMPTOMS.

BY WILLIAM GRAY, M.D., C.M., (Edin.),

(Publishers: H. K. LEWIS: London. pp. 71, 8vo.)

With a view to drawing attention to some of the special symptoms of Influenza, the work before us furnishes a description of some of its more unusual relationships. The author has had the advantage of considerable practice during the Influenza epidemics of recent years; and there is little doubt he has succeeded in making his descriptions both valuable and interesting to members of the profession.

INFLAMMATION OF THE BLADDER AND URINARY FEVER.

BY C. MANSELL MOULDER, M.D., (Oxon.), F.R.C.S.,

Surgeon and Lecturer on Surgery at the London Hospital; Examiner in Surgery at the University of Oxford, &c.

(Publishers: H. K. LEWIS, London, pp. 156.)

This book furnishes us with a valuable series of observations upon cystitis and urinary fever. Considerable attention is paid to those important points having a direct bearing upon the relations that exist between the walls of the bladder and the organisms that invade it. The principles of aseptic surgery still seem to stand in need of an advocate where the bladder is concerned, and the treatise before us, which has been ably and thoughtfully written up, will doubtless serve the useful purpose for which it is intended.

VITA MEDICA: CHAPTERS OF MEDICAL LIFE AND WORK.

BY SIR BENJAMIN WARD RICHARDSON, M.D., LL.D., F.R.S.

(Publishers: LONGMANS GREEN, and Co., pp. 96.)

THE volume before us forms more or less of an Autobiographical record of a very distinguished surgeon. Owing to his lamented death, before the last proof-sheets were revised, the work is now given to the world by his son, Mr. BERTRAM RICHARDSON. It would not be possible in a brief and cursory notice like the present one, to afford any adequate idea of the variety of subjects embraced in the book which has scarcely a dull page. The revolutions that have taken place in Physic alone during the author's medical career, extending as it did over half a century, provide interesting reading. Indeed not only every medical man, but the general reader should not fail to find something both to entertain and to edify, in the subjects to which that long and eminently useful life was devoted.

Government Medical Gazettes.

GOVERNMENT OF INDIA.

To be Surm. Col.

Brig.-Surg.-Lt.-Col. Thomas Holbein Hendley C.I.E., Bengal Estab. 2nd April 1898.

Sur.-Majors to be Surm.-Lt.-Cols., 30th March 1898.

Bengal.—Jarlath French-Mullen, M.D.; Eugene Curtin, Andrew Duncan M.D.; George Frederick Nicholson M.D.; Samuel Ferguson Bigger, Sir George Scott-Robertson, K.C.S.I.

Madras.—Thomas Henry Pope, M.D.; Robert Pemberton, Damodar Purshotam Warlicker, James Joseph Moran, M.D.; William Adair Quayle, M.D.; Henry Armstrong.

Bombay.—Charles Monks, Phiroosha Jamestjee (Damania), George Henry Bull, M.D.; Frederick Fitzgerald MacCartie, C.I.E.

Surm.-Captains to be Surm.-Majors, 1st April 1898.

Bengal.—William Grant Thorold, Patrick Hehir, M.D.; Lionel John Piesani, Basanta Kumar Basu, M.D.; Narendran Prasanna Sinha, William Rice Edwards, M.D.; Charles Macgregor, John Fenton Evans, George James Hamilton Bell, Joseph Thomas Daly, Henry Fooks, Ernest Hudson, Arthur William Dawson, M.D.; William Henry Banner Robinson.

 Dmpt., to do piquet duty, Sangor Ry. Stn., from 30th May
 1908.

BURMA GOVERNMENT.

Hosp. Asst. K. Kanaren assumed charge Genl. Hosp. Akayab, 4th Dec. 1897.

Hosp. Asst. K. Kanaren assumed charge Dispy. Zigon, Tharrawaddy dist., 24th June 1898.

Hosp. Asst. P. V. Govindarajulu Mendalliar assumed charge Genl. Hosp. Rangoon, 15th July 1898.

Hosp. Asst. No. 100, Shakti Choenoonaddin assumed charge Police Hosp., Katha, 12th July 1898.

Hosp. Asst. Makhhan Lal Warma, to Shwabo dist., 15th July 1898.

Hosp. Asst. T. J. Venotachellum Waldu assumed charge Police Hosp., Kindat, 9th July 1898.

Hosp. Asst. Bishan Lal, assumed charge at the Ry. Dispy., Naba, 10th July 1898.

Hosp. Asst. Bander Singh assumed charge at the Civil Dispy., Katha, 15th July 1898.

Hosp. Asst. Chowdhry Mowla Bakhsh, on transfer to Mergui dist., relinquished charge Genl. Hosp., Rangoon, 15th July 1898.

Hosp. Asst. C. Krishnan assumed charge Police Hosp., Katha, 10th July 1898.

Hosp. Asst. Maung Po Mya assumed charge Genl. Hosp. Rangoon, 15th July 1898.

Hosp. Asst. Maung Maung assumed charge Genl. Hosp. Rangoon, 15th July 1898.

Hosp. Asst. No. 197, Daniel Paul, assumed charge, Police Hosp., Magwe, 28th July 1898.

Surgn.-Major E. P. Frenchman, on proceeding on three and half months' privilege leave, made over, and Surgn.-Capt. E. J. Moses assumed charge of the duties of the Civil Surgn., Bessid, 30th June 1898.

Surgn.-Capt. J. H. Sellick, made over, and Surgn.-Capt. T. W. Stewart assumed charge, duties of offg. Supt. and Med. Officer, Central Jail, Insein, 30th June 1898.

Hosp. Asst. Khabiruddin, relinquished charge, Contagious Disease Hosp., Rangoon, 2nd July 1898.

Hosp. Asst. F. A. Jeyceia Rao, leave for three months, 30th June 1898.

Hosp. Asst. Nawab Khan, assumed charge, Outpost Hosp., Tagaung, 23rd June 1898.

Hosp. Asst. Guru Das Barwah assumed charge, Outpost Hosp., Talowgyi, Myitkyin, 25th June 1898.

Hosp. Asst. P. K. Panigrahi assumed charge, Outpost Hosp., Shwedwin, Upper Chindwin dist., 8th May 1898.

Hosp. Asst. Makhhan Lal Warma assumed charge, Civil Hosp., Kyaukse, as a supery., 5th July 1898.

Hosp. Asst. Maung Me Nyo relinquished charge, of duties, Police Hosp., Shwabo, 9th May 1898.

Hosp. Asst. Amirata Lal Guha assumed permanent charge, Allo Hosp., Pokokee, 23d June 1898.

Hosp. Asst. Bishan Lal assumed charge, Police Hosp., Katha, 4th July 1898.

Hosp. Asst. Sawan Singh assumed charge, Outpost Hosp., Myothit, Bhamo dist., 22nd June 1898.

Hosp. Asst. T. Venkataperumal Reddy assumed charge, Outpost Hosp., Nampang Bhamo dist., 21st June 1898.

Hosp. Asst. Husein Bakhsh assumed charge Outpost Hosp., Kabang Ruby Mines dist., 28th June 1898.

Hosp. Asst. K. G. Mariammas Naidu assumed charge Contagious Disease Hosp., Rangoon, 2nd July 1898.

ASSAM GOVERNMENT.

The services of Surgn.-Major E. F. H. Dobson, I.M.S., Civil Surgn. Goalpara, are replaced at the disposal of the Govt. of India Home Dep.

Babu Hara Lal Shome is confirmed as Third-grade Hosp. Asst. in Assam, from 26th March 1898.

Privilege leave for three months, is granted to Hosp. Asst. Nabin Chandra Das, Bhoganj Dispy., Sylhet dist., from 6th July 1898.

Hosp. Asst. Annul Chandra Das Gupta, a Supy., Sylhet dist., to the med. charge of the Bhoganj Dispy., in that dist. from 6th July 1898.

Babu Satia Chandra Chatterji, a passed student Campbell Med. School, Calcutta, is appointed on probation for six months, a Civil Hosp. Asst. in Assam, and is posted to Sylhet for duty as a Supy. from 9th July 1898.

Hosp. Asst. Satia Chandra Chatterji, has passed the English Qual. Exam., 14th July 1898.

Hosp. Asst. Brajendra Mohan Goswami, a Supy., Mibangar dia to the Titabar Dispy. in that dist. from 15th May 1898.

Hosp. Asst. Fakhrul Islam, Titabar Dispy., Sibesagar dist. to Naga Hills dist. Wokha Dispy., from 31st May 1898.

Hosp. Asst. Raman Mohan Das, Naga Hills dist., to Sibesagar dist., Titabar Dispy., from 15th June 1898.

Hosp. Asst. Bishnu Charan Banerji, Bhangra Dispy. to Manipur Dispy., and Jail and Police Hosps., from 16th June 1898.

Hosp. Asst. Brajendra Mohan Goswami, to Darrang dist. as Supery. for duty under Civil Surgn. from 24th June 1898.

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Rs. 1 for subscribers and Rs. 2 for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTH.

PISANI.—On the 10th July, at Aligarh, wife of Surgeon-Major L. J. Pisani, Indian Medical Service, of a son.

MARRIAGE.

HENDLEY—PETHERIE.—On the 7th July, at the Parish Church, Eastbourne, by the Rev. J. H. Copleston, Rector of Offwell, Devon, assisted by the Rev. H. B. Outley, Vicar of the Parish, Surgeon-Captain Arthur Gerwase Hendley, I.M.S. youngest son of the late Surgeon-General John Hendley, C.B., to Jessie Graham, eldest daughter of J. H. Patrie, Esq., 5, South Cliff, Eastbourne.

DEATHS.

MORICE.—On the 2nd June 1898, at 29, Trebovir Road, South Kensington, Surgeon-General John Charles Morice, I. M. S., aged 61 years. (Other papers, please copy.)

RUSSELL.—At Bareilly, on 22nd June, from heat apoplexy, Surgeon-Captain A. W. F. Russell, I. M. S., youngest son of A. E. Russell, Esq., The Gabbles, Crockham, Winchfield, Hants, in his 29th year.

CHERRY.—On the 27th June, 1898, at Cawnpore, Hubert Maxwell, eldest son of Surgeon-General William Cherry, of Oreywell, New Ross, Ireland.

MILES.—At his residence, Kensington Road, Bangalore, on the 18th July, 1898, of Bright's disease, Surgeon-Lieutenant, H. E. Miles, I.S.M.D. Aged 51 years.

NOTICES TO CORRESPONDENTS.

R. E. W. (Dehra Doon).—Many thanks. We gladly welcome the return of old friends.

E. M. (Cawnpore).—We know of no institution which assists indigent lads to prosecute medical studies.

G. E. C. (Bandikui).—Thanks for your paper. Next number.

S. N. S. (Tala).—Your name has been registered.

P. H. (Jullunder).—Hospital Assistants are members of the Subordinate Medical Department and 100 of the Army Hospital Native Corps. The latter are menials the former educated medical assistants.

J. P. P. (Tenkasi).—Thanks for your paper.

A. S. (Merta).—The case you describe is one probably of Hysteria.

Another interested.—The matter of the Chief Medical Officership of the E. B. S. Ry., is now before the Government of Bengal. We trust a suitable man will be appointed.

S. Y. K. (Manyzeer).—Hospital Assistants are not entitled to put the word Doctor before their names. Read back numbers of the Record for your further enquiries.

M. C. C. (Shillong).—You will find all the information you want in the new edition of the Medical Register and Directory of the Indian Empire.

ORIGINAL ARTICLES.

THE ARMY MEDICAL STAFF: ITS PAST SERVICES AND ITS PRESENT NEEDS.*

By PETER ALEXANDER YOUNG, M.D.,

Fellow and Treasurer of the Royal College of Physicians of Edinburgh.

AT the present time there has been much discussion regarding the medical staff of the army and the difficulty of getting candidates to offer themselves for the examination for commissions in the service.

The main objection seems to be the absence of definite rank and titles. The titles at present in use are so cumbersome that they can only be used in official correspondence, and cannot be employed in ordinary social life; the result being that medical officers, after a long and distinguished career, retiring with say the nominal rank of major-general, are invariably addressed in civil life as plain "Dr." or "Mr."

In the service the supposed rank of the medical officer is set aside, and he is spoken of as simply "the doctor." He is thus deprived of the prestige the military rank confers, he finds himself at a disadvantage when associating with other officers, and he feels that under many circumstances he is snubbed. Although exposing himself equally with other officers to the perils, casualties, and fatigues of campaigns, he has been spoken of in the highest military circles as "a civilian." Can it be wondered at, then, that young men of spirit and talent hesitate before they join a service where they may be subjected to social disability, and cannot enjoy the status that military rank should give?

It may be of advantage and interest, before further discussing this subject, briefly to look at the evolution of the medical department of our army, and to find if, during the past two hundred years, it has not, by its services to the country, deserved more consideration, and earned for itself a right to be a component and military part of our army. For an account of the chief facts of this historical sketch, I am very largely indebted to Surgeon-Major ALBERT A. GORE, who, in his work, "Our Services under the Crown," has given a most interesting account of the medical service of our army.

In 1680, the army consisted of but four regiments, and, when Tangiers belonged to Britain, medical officers were sent with the army of occupation. The surgeons were attached to regiments, and their names appeared in the Army List. In the Guards they received 4s. a day, and had a horse to carry their chests. Surgeons' mates were also attached to regiments, but, as they received their warrants from the regimental colonels, their names do not appear in the Army List. The Company of Surgeons of London seems to have provided the surgeons and surgeons' mates. About this time the surgeons are returned before, and presumably ranking before, captains. During the reign of JAMES II. it was by no means uncommon for medical officers to hold double commissions—purchasing their commissions as ensigns, and obtaining 2s. 6d. a day for extra hospital service. Medical officers who held double commissions were

expected to perform combatant duty, such as guard-mounting and attending courts-martial. They ranked as staff officers. In 1685, we have mention of surgeon-general, who occupied the chief position in the Army Medical Service. The officer had, as one of his duties, to certify soldiers who had lost a limb, in order to get a bounty of one year's pay. Sometimes regiments went on board ship to act as marines. When this occurred their surgeons did not go with them, but remained on duty ashore.

In the reign of WILLIAM III. we find the title of physician-general occurring as the medical head of the army in Ireland. Dr. (afterwards Sir) PATRICK DUN was the first to fill this post. For army service he had 10s. a day. Money left by Sir PATRICK went partly to found the hospital in Dublin called after him, and which exists to this day, and where soldiers' wives are at present trained to become army midwives. Sir THOMAS MOLYNEUX, who afterwards occupied the position of physician-general, was the first medical baronet of Ireland. Thomas Proby, who was surgeon-general of the army in Ireland at the end of the seventeenth century, was *ex officio* examiner for the diploma in surgery. In 1697, the Company of Surgeons of London had a bowl of 168 oz. presented to them, "in acknowledgment of their services in examining the surgeons for the army and navy." Marlborough took a great personal interest in the surgeons, with whom he was in constant communication. At Blenheim one in five soldiers was wounded. After Malplaquet 12,706 wounded fell to the allied surgeons. In 1795, RADCLIFFE attended Lord ALBEMARLE at Namur in camp, and also WILLIAM III., and received a fee of £1700, and declined a baronetcy. In 1714, the terms surgeon and surgeon's-mate were used instead of chirurgeon. During the reign of GEORGE I. a surgeon and surgeon's-mate were attached to the Ordnance Department, which afterwards became the Royal Artillery. During the time of GEORGE II. an increase of the army took place, and the regimental staff was arranged thus—chaplain, surgeon, adjutant, quarter-master. In 1743, GEORGE II. was present at Hoch with the army under Lord STAIR, and JOHN RANBY, prime sergeant surgeon, was in attendance on the king—the last time a surgeon to the king was present in action. During this campaign it was arranged between Lord STAIR and the French commander that the hospitals should be mutually protected, an arrangement strictly observed by both sides. Dr. FRANCIS HORNE, afterwards Professor of Materia Medica in the University of Edinburgh, served in Flanders as an army surgeon. Sir JOHN FRINGLA wrote of the medical arrangements at Dettingen, which were chiefly regimental, with general hospitals in the rear. This surgeon accompanied the army to Scotland during the rebellion of 1745. When the troops advanced on Carlisle the sick were left en route in the towns, under civil surgeons and apothecaries. After Culloden, two melt-barns at Inverness received the wounded—broadsword cuts were common, and healed well. Sir JOHN FRINGLA retired with a baronetcy, and was appointed physician-in-ordinary to the king. In 1746, Sir HANS SLOANE was created the first medical baronet in England by GEORGE I., and appointed physician-general to the forces. He served in Jamaica on the staff of the DUKE OF BUCKINGHAM. In 1719, he

* Reprinted from the Edinburgh Medical Journal by request.

was presented of the College of Surgeons, and succeeded Sir ISAAC NEWTON as president of the Royal Society. He was appointed apothecary-general by GEORGE II. in 1747, and had the privilege of providing the medicines for the land forces of Great Britain. Properly equipped hospitals were introduced by MIDDLETON, surgeon to the forces, in 1748, patients being provided with separate beds, clean linen, and trained nurses.

Up to 1746, there was no medical inspection of recruits, but after this time rapture was assigned as a disqualifying disability. In 1751, medical officers were the uniform of the corps to which they belonged. The medical officers of the 89th Foot, in 1787, were the first surgeons of the British Medical Staff who saw service in Bengal.

In 1756 a Hospital Board was formed to control medical affairs, but after a time fell into disuse, and the principal hospital surgeons did the work of the Board.

Oliver Goldsmith obtained a nomination for the East India Company as surgeon's-mate, but failed in his examination at the College of Surgeons. A surgeon's pay in 1760 was £73, while a captain's was £182.

BROCKLESBY, a distinguished army surgeon, considered that the pay of the army surgeon was too small. He thought that it should at least be £250, as it had to be obtained by purchase, and cost £500. He was of opinion that the medical service should be recruited from young gentlemen, duly qualified, of a good education and liberal turn of mind, with £700 in their pocket to purchase their commissions. He recommended that the examination of candidates should be transferred from Surgeons' Hall to one of the censors of the College of Physicians, conjointly with a physician who knew the proper characteristics requisite in aspirants for the post, it having been the practice, in many instances for some great man to recommend raw youths just released from their apprenticeship. BROCKLESBY recommended the use of hut hospitals, which resulted in a lessened mortality amongst sick soldiers.

DONALD MONRO, a near relation of MONRO *primus*, Professor of Anatomy in the University of Edinburgh, was physician to St. George's Hospital and His Majesty's forces in 1761.

Medicine and surgery were considered distinct professions in the army at this period, but a physician or surgeon could hold a regimental appointment. The department was governed in London by a physician-general and a surgeon-general.

The morning visit to a military hospital seems to have been a very perfunctory affair—consisting in calling the roll, and ordering something the patient could not procure from the half-crown a week allowed, which was expended under the direction of the surgeon by the hospital sergeant. The mates did the work, and were frequently warned not to use too much medicine, as it was provided out of the senior officer's annual allowance. Mates were promoted to the rank of surgeon only after a long period of service, and then only by a lucky chance. They were not required to pass an entrance examination. Previous to 1785, surgeons' appointments were bought and sold, but after this period the sale of commissions was legally suppressed, but for long after was still carried on. The officers required simply a certificate from a private

teacher to get an appointment to a vacancy in Surgeons' Hall certificate being necessary. JOHN HUNTER, the famous surgeon, said "that it was not necessary for a man to be a surgeon to practice in the army." Promotions were few and far between; surgeons could sell their commissions if they wished to retire, but they had no superannuation allowance. Surgeons to general hospitals received about £200 a year, regimental surgeons £100, and apothecaries 10s. a day.

The physicians of the army, who were highly educated and often University graduates, were looked upon as the *élite* of the profession, and paid very much in advance of regimental surgeons. Occasionally during war a surgeon was raised to the rank of a physician. Surgeons'-mates, although non-commissioned, enjoyed some of the privileges of the surgeons, and had a place assigned to them on parade. The titles master-surgeon, deputy-director, and director of hospitals are first found at this period.

In 1787 we first find the title surgeon-major. The higher titles appeared during a war, when staff surgeons and physicians were selected from civil life on the spur of the expedition, and very rarely from the regimental surgeons.

In 1786, JOHN HUNTER was made deputy surgeon-general, and in 1791 appointed to the joint office of surgeon-general and inspector of regimental infirmaries. He had served as senior staff surgeon at Belleisle in 1760, and in Portugal in 1768, when he was designated "surgeon-general, deputy purveyor-inspector, and director of general hospitals." JOHN HUNTER made it a rule that the higher ranks should be filled from the lower, but after his death the arrangement that Oxford and Cambridge graduates, or members and licentiates of the College of Physicians should fill the highest grades, was reverted to. After his death, the office of surgeon-general merged into a Board consisting of physician-general, surgeon-general, and one inspector of regimental infirmaries. This arrangement continued till 1808, when it consisted of a director-general and the principal inspectors. After the peace of 1815, these inspectors ceased to be borne on the return of the staff of the army.

Sir LUCAS PEPYS, who was physician-general and president of the College of Physicians, recommended physicians for the army. The Surgeon-general recommended surgeons for the post, and he could delegate his duties to superior surgeons, who were called principal officers of hospitals. The surgeons were placed under the inspector-general. This complicated system was proved inefficient, and led to a new order of inspector-general, appointed from the surgeons of the line, as knowing military duties better. The surgeons provided diet for the sick from a fund allotted for their support—the prices were checked by the commanding officer of the regiment, who signed the surgeon's accounts.

The Duke of York nominated for the office of physician to the force. Dr. JACKSON, without the intervention of the College of Physicians, thus breaking the monopoly. Dr. JACKSON had served in America and the Peninsula with great distinction. He particularly urged the claim of the medical department of the army to a share of the military honours and distinctions, on the grounds "that it shared in the fatigues and dangers of war, and, in just return, it is entitled to a share of its advantages." He

Further says: "If a medical officer be professionally skilful and morally correct, he is entitled, as he is eminently useful in his vocation, to a respectful place of rank in the military fabric; the medical officer claims to himself the rank of a gentleman, and the respect which is due to a man of science. Rank is everywhere the gift of power. If the officers of the medical staff were advanced by a just and legitimate rule of gradation, the staff surgeons would class with captains, the physicians with lieutenant-colonels, and the physicians-in-chief with generals. The rank accorded to the medical officer does not injure or even interfere with the military. Rank is of no intrinsic value to the man of science, but the opinion connected with rank makes an impression on the soldier which aids materially in giving force to medical authority, and consequently to medical utility."

Until the termination of the year 1793, the rank of the medical staff of the British army was not distinctly defined. The assistant-surgeon joined a regiment with the rank of lieutenant, and the surgeons took rank with captains, according to date of commission. When staff-surgeons were introduced they did duty in the general hospitals, and were quite distinct from regimental surgeons. Assistant-surgeons followed in rear of the fighting line, and the quarter-master, pioneers, and band removed the wounded to rear, beyond the range of fire. At this time the term Medical Staff was introduced. In 1802, surgeons, called district surgeons, to examine recruits were appointed.

At the beginning of this century, there was some difficulty in getting officers to join the medical staff, and the Dublin School was requested to send officers, and inducements were held out to them to join the service. In 1804 a warrant was issued, granting higher rates of pay. Infantry and cavalry surgeons received 11s. 4d. per diem, and both had to keep a horse. Inspectors and deputy-inspectors of hospitals were nominated in 1805. Sir JAMES M'GRIGOR, a distinguished graduate of Aberdeen was one of the first of those appointed. In 1794, he had referred to the difficulty in getting medical officers, and says: "It is not only in the sense of humanity, but in that of sound policy and real economy, that the State should provide able medical and surgical advice for the soldiers when sick or wounded. I look upon it to be an implied part of the compact of the citizens with the State that whoever enters the service of his country as a soldier, to fight its battles, should be provided with the same quantity of medical aid, when sick or wounded, which they enjoyed when a citizen."

As a result of the disaster to the Walcheren Expedition, important changes were made in the constitution of the Army Medical Department. The army Board was dissolved, and a director-general and principal inspector were appointed. Dr. WELLS was the first director-general.

During the Peninsular War, Sir JAMES M'GRIGOR induced the DUKE OF WELLINGTON to mention in the *Gazette* the services of the medical officers. The DUKE did this, for the first time in the history of the army. In this war the want of an ambulance with the British army, and of a hospital corps to furnish the means of assisting and conveying the wounded, was very much felt. Sir JAMES M'GRIGOR was director-general for thirty-five years, and

received during his term of office £2000 a year. He had the relative rank of major-general, and retired in 1851. Sir ANDREW SMITH, succeeded, and was called superintendent of the Army Medical Department. He received only £1800 a year. The organization of the Army Medical Department underwent no material change till the end of the Crimean War. The want of a properly trained corps was much felt, the bandmen carrying off the wounded on stretchers. They had no special knowledge of how to give first aid to the wounded, and this necessarily increased the work of the medical officers. The department suffered in this general break-down of all the arrangements. Although individually the medical officers behaved well and did their part bravely, yet they were dreadfully hampered by the want of supplies and medical comforts. More than one medical officer took combatant rank, and afterwards commanded his regiment. Assistant-Surgeon WILSON, of the 7th Hussars, "with the greatest gallantry and coolness, assembled a few men of the Guards, and led them to the charge, and utterly routed and dispersed the Russians threatening the Duke of Cambridge's life, whose horse was killed under him. At the close of the day, Mr. WILSON, was called to the front of his regiment and publicly thanked for saving, in all probability, the DUKE's life."

By the end of the Crimean War, the Medical Department was in a much better state of efficiency than it was at the beginning. A medical staff corps was formed, with distinctive uniform.

A Royal Commission had reported that the weakest point in the Medical Department of the Army was the want of prestige, to give the officers that due importance among their brethren, so essential to the efficient performance of military duties. In a memorial of the medical officers to the Secretary of War, they say: "We submit that we ought to be classed amongst the purely military branches, and reap our share of the honours accorded to them, the exclusion from which, in all campaigns, we deeply feel."

The corporations of Great Britain and Ireland expressed the opinion that—(1) "The existing regulations of the service did not appear to hold out sufficient encouragement, either by present or prospective remuneration and rank, to induce students of the higher order, as to education and attainments, to seek for these appointments"; and (2) "that considering the valuable services which, by universal acknowledgment, were rendered by the medical officers during the late campaign, their self-sacrifice, moral courage, and devotion to their arduous duties, under trying circumstances, the present seems a suitable opportunity for the recognition of the claims of this important branch of the service to higher status and emoluments." The Commission reported: "It is not, however, by money alone that the ablest and most accomplished men will be attracted to the army medical service; the rank, the position, and the honours which are to be obtained constitute perhaps, the stronger inducements to the higher class of minds."

When the commander-in-chief assumed command in 1855 of the Royal Artillery and Royal Engineers, Sir ANDREW SMITH, became "Director-General of the Army and Ordnance Departments."

At the close of the time of medical officers were as follows: *Surgeon-General of Hospitals; Deputy-Surgeon-General of Hospitals; Staff or Regimental Surgeon, after twenty years' service; Surgeon-Major; and Staff or Regimental Assistant-Surgeon.* Mr. ALEXANDER at this time was *Director-General*. In 1860 took place the first examination for entry into the Army Medical School, which was opened at Fort Pitt, Chatham. In 1878 a committee appointed by Lord CAMERBORN reported, amongst other points, in favour of (a) giving a new title to the army medical service, such as "Royal Army Surgeons," or "Royal Medical Staff"; (b) that the Army Departments should have no precedence inter se, but be arranged alphabetically; (c) that honours and good service pensions be bestowed on the scale applicable to combatants; (d) that the names of the Queen's honorary physicians and surgeons be printed in the *Army List*, immediately after those of Her Majesty's aides-de-camp. They further thought that the medical officers should be associated with the combatant rather than with the administrative services.

The regimental system was abolished in 1874. Medical officers now belonged to the Army Medical Department, and were only attached to regiments for duty. They wore a departmental uniform, and no longer the regimental uniform they formerly did. The reason of this change was mainly that it gave the department more elasticity. When officers belonged to a regiment, under the regimental system, there were usually a surgeon and two assistant surgeons in each regiment. On active service all these medical officers might not be required with their own regiment, while some other regiments might require more than their complement of medical officers, owing to the regiment being broken up into several detachments, or from some other cause. The medical officers could not be changed from one regiment to another as they were required. Under the departmental system this could be easily effected, as the medical officers did not belong to regiments but were only attached to them, and could at once be sent where required. At first the departmental uniform was scarlet, while the uniform of the Medical Staff Corps, which was under the command of the medical officers, was blue. Gradually the uniform of both officers and men was made the same, and a blue uniform adopted, as it is at the present time.

In 1880, Lord CAMERDOWN's committee recommended that for the title "Medical Staff," which had two or three years before been introduced instead of the "Army Medical Department," the title "Royal Medical Staff" should be adopted, and that compound titles showing relative army rank, should be introduced. The titles were surgeon-general, surgeon-colonel, surgeon-lieutenant-colonel, surgeon-major, surgeon-captain, and surgeon-lieutenant. This recommendation was not at once agreed to, but a part of it, as far as titles and relative rank are concerned was introduced afterwards when Mr. STANHOPE was War Secretary. The titles used were changed slightly—surgeon major-general being employed instead of surgeon-general, and an additional grade, brigade-surgeon-lieutenant-colonel added.

In the month of April of this year the present Government promised to give medical rank and titles to their

own corps, and possibly get the medical staff corps on a footing somewhat similar to that of the Royal Engineers. It is presumed that medical officers will be styled captain or colonel, Medical Staff Corps, respectively Royal Medical Corps. This latter is doubtful. The numerous compound titles will not be used, and medical officers will be called by titles which can be employed in the social circle and civil life, and will be thus placed on an equality with other officers. This is a point that army medical officers have contended for since the introduction of the departmental system. When medical officers were regimental officers the question of rank did not enter acutely into their consideration. If they were pleasant and made themselves agreeable, their position was assured. Being officers of their regiments, they took a great interest in all that concerned its welfare; they were members of the mess, and one of them was often president. Rank was not considered, and the want of titles was not felt. The medical officers of the navy are in that position now; they are officers of the ship, and rank does not come prominently forward. When, however, the Medical Department was formed, and medical officers were only attached to regiments, the want of distinct titles and rank was felt, and medical officers suffered under a disability which was the cause of much discontent. The desire for command outside their own corps has never been expressed—all that was contended for was substantive rank and title, which would convey to the mind of the soldier and the public an exact idea of the position of the officer in the army. The non-commissioned officers of the Medical Staff Corps, when promoted to commissioned rank, are called lieutenants and captains. Officers who have to do with the transport and the commissariat of the army, and who are not nearly so much exposed to the casualties of war as medical officers, have rank and titles. Even the bandmaster of the Guards ranks as a lieutenant in the army. Why were medical officers alone excluded from this, to which they felt themselves entitled?

The question of courts-martial, mixed boards, and some sanitary boards also required reconsideration. On these, medical officers have no seat, but are requested to attend to give evidence, and have no deliberative vote. The question of pay and pensions is not a burning one. The paucity of numbers renders medical officers liable to frequent changes of station, entailing much expense and great inconvenience. The same cause also leads to the time of service in India being too much prolonged. This further prevents medical officers having study-leave, to enable them at some civil hospital to go through the necessary study to keep themselves abreast of the advances in medicine and surgery. These and other causes, which need not be particularly mentioned here, have prevented men of ability and ambition seeking the medical service of the army as a career, who under more favourable conditions, might have been attracted to a service which in many ways might be most desirable.

If it be the duty of the Government to arm the soldiers of our army with the best weapons of defence as well as of offence, as every reasonable person will concede, it is surely their duty also to provide the best means of healing the soldier when stricken by disease or wounds in the service of his country, and to have a thoroughly

equipped, well trained, and appointed medical department.

At the present crisis this can only be obtained by granting the privileges and status indicated in the preceding pages, the more especially when the demands are so moderate, easily given, and will lead to no increased cost to the country.

Since the above was written, Lord LANSDOWNE has intimated that the Government intend to grant definite rank and titles to the Medical Department. Medical officers of the army will now be styled Lieutenants, Captains, etc., up to the rank of Colonel. As the rank of General is to be reserved for those having army command, the highest title in the Medical Department will be Surgeon-General, ranking as Major-General, Her Majesty the Queen intends graciously to form the Medical Department into a Royal Corps, under the title of "The Royal Army Medical Corps." These important concessions should now cause the friction between the Government and the Medical Department of the army to cease, and lead to medical men of ability and position joining the army in sufficient numbers to fill all existing vacancies, and if necessary increasing the numbers of medical officers which will be required for the contemplated enlargement of the army.

The medical officers of the army and the profession generally are much indebted to Lord LANSDOWNE for his courage in making these important changes.

—:— INTESTINAL WORMS.

By SURGEON MAJOR R. E. WRAIGHT.

Bengal Medical Service (Retired), Dehra Dun.

THE presence of worms in the intestinal canal carries with it such decided evidence of the existence of disease, that it has from the earliest ages been a constant subject of investigation with medical writers. HIPPOCRATES and GALEN have written concerning worms; and in our own times the attention of many distinguished pathologists has been directed to the same inquiry. With all this, it is singular how little is really known concerning them which may illustrate their origin, or direct us in our methods of treatment. It is true, indeed, that their varieties and everything relating to their natural history has been fully and ably detailed; but to the practitioner of medicine these are mere objects of curiosity, which may claim attention in an hour of leisure, but are wholly useless as applied to practice. That which to him would be desirable, a knowledge of the general pathology of worms, of the state of body in which they originate, of the symptoms which they immediately excite, and of the extent to which they influence the production, or modify the symptoms and progress of other diseases—is, it must be confessed, still involved in remote obscurity. Yet these are points, which will be found in practice, of essential importance, and the investigation of which appears to require only patient attention. We cannot doubt that the subject will some day receive that full investigation which it merits.

The intestinal canal in the human race is infested by five different kinds of worms viz., the *ascarides lumbricoides* or large round worm, the *ascarides vermicularis* or

common thread-worm, and three varieties of *tænia*, namely, *tænia solium* or common tape-worm, *tænia medio-canellata* or hookless tape-worm, and *tænia lata* or broad tape-worm, the latter almost peculiar to inhabitants of Switzerland, Russia, and Poland. Of these the two latter are so rare as not to require a detailed notice here. Our attention may be confined therefore to the three varieties well known under the familiar appellation of the round worm, the tape worm, and the thread-worm. In treating of them I shall briefly allude to such circumstances only in their history as appear susceptible of practical application.

1. The *ascarides lumbricoides*, or round worm, resembles in its general aspect the common earth-worm; but there are many points of difference between them, as well in their external appearance as in their internal structure. It is from eight to twelve inches in length or longer, and infests principally the small intestine. It sometimes ascends to the stomach, and has been found in the wind pipe, mouth or nostrils, a few instances occur of its being solitary. In the generality of cases, however, there are at least two, and occasionally thirty or shoals in number, they are much more common in the intestines of poor wretched and neglected children from 4 to 6 years of age than in those of persons full-grown or advanced in life, in fact, they are rarely met with after fifteen years of age.

2. The *tænia*, or tape-worm, white, flat, jointed, head small, triangular, flat and armed with hooks and suckers, is frequent in this country, both among children and adults. This worm is often very long, extending in many cases to twenty or thirty feet. It occupies the upper part of the intestines, and feeds on the chyle. It is commonly imagined to be solitary, and has from this circumstance been called *tænia solium*. This is not, however, strictly the case. The detached joints of this worm measure on the average a quarter of an inch wide by half an inch long and have the appearance of gourd-seeds, and it has hence received the name of the *vermis cucurbitinus*. It has been supposed that each joint possesses a kind of independent life; but this notion is altogether unwarranted.

3. *Ascarides vermicularis*, or thread-worms commonly called seat worms, a small creeping animal about half an inch, or even more in length, having the appearance as its popular name implies, thread-like, inhabiting the lower bowel close to the fundament and remarkable for their very quick motion. Their true domicile is the mucus and thin faces of the rectum and colon, they occasionally also find their way into the vulva, vagina and urethra of female children. Mucus is probably the food by which they are nourished. Thread-worms are probably the most common of all intestinal parasites; they infest persons of all ages, but children much more frequently than adults, they are, however, never found in the sucking infant. When women are affected during pregnancy, there is tendency to slight fever after delivery, and in my experience their children incline to eczema or other cutaneous disorders.

Symptoms.—The symptoms occasioned by worms are often very indistinct. They may be characterized generally as those of dyspepsia, irregular action of the bowels and nervous irritation. A sense of tightness

across the epigastrium, with inability to swallow, although the appetite was good, were the chief symptoms of tape-worm in a very severe case occurring in adult life which in times past fell under my care. I am not aware that it is possible to distinguish between the symptoms occasioned by the round and tape-worm. It can only be stated generally that the former produces symptoms of greater intensity, and being so much more generally found in children than the tænia, may commonly be suspected at an early period of life.

In adults, on the other hand, affected by symptoms of worms, the presence of tænia is rendered probable. Children who are troubled with worms complain of a gnawing uneasy feeling about the stomach, which is removed or diminished by eating. The appetite is deranged and variable, often more than ordinarily voracious. The belly is hard and turned, there is picking of the nose, hiccup, disturbed sleep, and grinding of the teeth. The countenance acquires a peculiar character (pasty and sallow), not easily described, but well known to those who have the care of children. Irregularity of the pulse, a slow remitting fever, and emaciation, are also observable in some cases. The irritation which worms occasion in the delicate constitutions of children has frequently brought on symptoms marking an affection of the brain and nervous system, such as giddiness, dilated pupils, and epileptic fits. Nothing perhaps more strikingly characterizes the presence of worms than certain anomalous symptoms, not observed in other diseases, or not accompanied by those which under common circumstances would appear along with them. A short, dry, sympathetic cough, or pains in the thorax without corresponding dyspnoea or affection of the pulse, are among the most unequivocal symptoms of worms which I have ever witnessed. In like manner, I have seen worms occasion every symptom of peritoneal inflammation, with the exception of hyperpyrexia. The difficulty of making an accurate diagnosis between the symptomatic nervous affections brought on by worms and genuine hydrocephalus has long been acknowledged. In many cases I presume it to be quite impossible, the two diseases existing together, and probably standing in the relation of cause and effect to each other. Worms will not only produce other diseases, but they will serve to modify the symptoms of such as may accidentally arise. This I have frequently noticed in the case of whooping-cough. It appears therefore difficult to assign any limits to the degree of constitutional disturbance which worms occasion. There can be no doubt that worms frequently exist in the intestines of adults (and even sometimes of children) for a very long time without giving rise to the least uneasiness. In this way only can we account for the extraordinary length which the tape-worm has frequently attained. In many cases the first notice of the complaint which the patient has, is the passing of some portions of the worm by stool. I have seen a person from whom they dropped in any exertion of walking. In other instances adults having worms suffer some of the inconveniences usually attendant on dyspepsia or colic. It is not often that the nervous system sympathizes at an advanced period of life. From incessant practice, medical men can tell many diseases by one look of the face, tongue and body, but the most experienced practitioner requires ocular proof of the presence of worms. From the foregoing it is evident

that thread-worm especially worry infants; round worms trouble older children, and tape-worms as said before are rare in early life. *Ascarides* seldom occasion anything more than local uneasiness, a constant, often intolerable itching about the anus and pudenda, with a sense of heat in the parts, tenesmus, and slimy stools. These uneasy sensations almost always come on towards evening, and prevent sleep for several hours. Although *ascarides* do not produce much constitutional disturbance yet they have been known to give rise to itching of the nose, restlessness, headache, giddiness, and some symptoms of dyspepsia. They are easily got rid of for the time by some bitter or oily injection.

Pathology.—I have already had occasion to remark how little practically is known regarding the state of the general system, and of the intestinal canal in particular, which leads to the formation of worms, or encourages their lodgment. They are commonly met with in persons of weak, enfeebled, or irritable habits, and therefore prevail much more extensively in children than in adults, in women than in men. Yet many persons in the prime of life are subject to worms who have no obvious marks of general weakness about them. Further, it cannot be doubted that a weak state of the digestive organs is that which principally leads to the production of worms; and this, as we shall see, is an object of first importance with a view to treatment. The disposition to form worms, when once begun, is with difficulty removed. In some habits it appears to be almost hereditary, and this I have observed to apply more particularly to the case of tænia. There is nothing in all pathology more obscure than the origin of intestinal worms. The theory which ascribes them to wula (an egg) which are taken into the body along with the food and drink, and find a nidus in the mucus and imperfectly assimilated food of a weakened intestine, might be supported if we found such viviparous animals in other situations. But this is not the case; they are incapable of existence for any length of time, except within a living animal body. Another supposition has also been stated that they are formed independent of ova, from matter or humours contained in the intestines, having previously no regular organization. This idea, however, is contrary to all analogy in the production of animals, where any satisfactory opportunity of investigating the subject exists. The origin of intestinal worms, therefore, is still, I am inclined to think involved in great difficulties, and probably may not soon have any satisfactory light thrown upon it, consequently we come to ask what are the causes of worms? The causes of worms in childhood are weak bowels. The ova introduced into the alimentary canal, probably with unripe fruit, raw vegetables, or with impure water, eating underdone pork and beef, an abundance of sweets; the neglecting of taking salt in the food, etc., one of the most frequent cause of tape-worm among Europeans is the eating of pork, more especially if it be underdone. Underdone pork is the most unwholesome food that can be eaten, and is the most frequent cause of tape-worm known, underdone beef also causes tape-worm; let the meat, therefore be well and properly cooked. These facts ought to be borne in mind by all, as prevention is always better than cure.

Treatment.—The treatment in worm cases has usually been conducted upon very empirical principles. The only object sought has been the expulsion of the worms, and this has in many instances been effected by medicines which have a tendency at the same time to weaken the action of the stomach and intestines, and thus to increase the disposition to form them. It would be superfluous and useless to enumerate all the anthelmintic remedies which have been recommended even upon high authority. Some of them are simply drastic cathartics, such as colocynth, scammony, aloes, calomel, and julap. These medicines in spite of their debilitating effects, are certainly of great importance, and it will be right in all cases to commence the treatment with some mixed purgative powder. That which operates quickly and which brings away most mucus will answer best. The legitimate reason indeed, for exhibiting active purges is to free the intestinal canal from that load of mucus in which the worms burrow, which is thrown out perhaps, in some measure, as a defence against them, but which in its turn interferes seriously with the process of digestion and prevents the due action of tonic remedies. The second class of anthelmintic medicines includes the oils, fixed and volatile, especially castor oil and oil of turpentine. They have been supposed to operate by blocking up the respiratory pores of the worms; but this theory can hardly be supported. The oil of turpentine, first recommended by Dr. Fawcett of Durham, in 1810, is undoubtedly the most certain of all the means we possess of directly removing worms. The full dose (in which it may safely be given even to children) is from four to six drachms, in milk, or mixed with peppermint water, either by means of mucilage or honey. It generally produces a slight stimulating effect that quickly passes off. The tania seldom or never resists it. The practitioner will remember that this is of all worms the most difficult to remove. The round worm, on the other hand, possesses great sensibility, and is very easily got rid of; and hence it is that such a variety of medicines have been found useful in its cure.

The third class of vermifuge medicines includes those which are bitter, acrid, or astringent, and which may be imagined to act either by a direct effect upon the worm or more probably by virtue of some tonic property. Of this kind are the absinthium or wormwood, the artemisia santoniolum or santonine, the male fern root, Ruta, the Spigelia marilandica, Kumala, Kousoo and Granati rud, cortex, the latter is an admirable remedy for tape-worm. The following is an old-fashioned form of worm powder, but it is effectual.

R.	Fol. absinthæ	ṣi
	" Ruta.			
	" Sennæ.			
	" Kousoo	ss ʒss
	Pulv. Rhei Rad	ṣi
	Croci (saffron)	ʒss misce

Sumat. ʒij, vel ʒiv omni mane.

Lastly, there are certain anthelmintics admitted into common practice whose operation it would be difficult to explain on any ascertained principle, such as stanesacore seeds, strong brine, and amafostida. Personally my faith is in malefern oil for tape-worm, santonine for

round worms, and for thread-worms an injection of steel and quassia. Some powerful drugs have also been recommended with the view of poisoning the worm, such as tobacco, arsenic, and belladonna. Too much stress has perhaps been laid on the administration of these vermifuges. Practitioners seem to lose sight of those greater principles which should regulate their treatment, and which are fairly deducible from the views already taken of the habit of body in which worms appear. The principal object is to strengthen the system generally, and the digestive organs in particular, and to excite that energy in the constitution which may enable the intestines to expel the worms and to resist their subsequent formation. To attain these objects we proceed as in ordinary cases of dyspepsia. Digestion is to be promoted, in languid habits by the use of aromatics, bitters, and carminatives. A regular action of the bowels is to be kept up, and accumulation prevented, by laxative doses of Liquid Extract of cascara sagrada or any similar adjuvant. Lastly, the general system is to be strengthened by daily exercise in the open air, by the worm, both, and by the use of some mild preparation of iron, such as the Ferri Peroxide Hydrat, the Ferri tartaratum and the Tinct. Ferri. Perchloride. The following powder may be recommended for weakly children.

R.	Ferri Tartaratum	gr. iiii.
	Pulv. Rhei Rad	gr. i.
	Quinæ sulph.	gr. i.

Pulv. Cinnam Comp. gr. ii. misce fiat pulvis, ter in die sumendus.

Dr. Waring in his valuable little book on Indian bazaar medicines recommends pumpkin seeds, betel-nut, garlic, butan seeds (pulas-ko-binj) vernonia seeds (Somraj Buk-ohi), the fresh milky juice of the unripe fruit of the papaw tree (Papaiyah), sulphur, etc. besides the advertised nostrums which are often considered powerful remedies and cures for worms, but there are no such specific cures, these nostrums being pernicious purgatives only. Prophylactics. Having regard to the development and manner in which intestinal worms gain access to the human body, the obvious means of prevention include (1) the purity of our drinking water; (2) the thorough washing of all uncooked vegetables with a stream of pure water, to carry off all deposits from the surface; (3) the thorough cooking of all meat, especially pork, from which tape-worms originate; (4) a liberal allowance of salt with the meals is also desirable. The stools of those suffering from worms should be disinfected and buried to prevent the spread of the disease by the ova being taken into the bodies of animals used as food such as the sheep, swine or oxen. Persons with worms should also always occupy separate beds or the malady may perhaps be incautiously communicated. Where convenient, it might be advisable somewhat to improve health first by a trip to the hills, and young medical men will doubtless be surprised to find how difficult it may be to effect a cure in worm cases.

in several points. Her temperature in the mouth and in the axilla was 99°; whilst her rectal temperature, at the same time, was 105°. So also, is another case where the axilla and mouth showed a subnormal temperature the rectum registered 108° at the same moment. I believe the rectum is the proper place to take the temperature in such cases and were any one to tell me that he had seen a case of peritonitis with a subnormal temperature I should ask him 'where' the temperature was taken.

One of the most constant symptoms of acute septic peritonitis is acute intestinal obstruction. The intestine is very much like a knee-joint or hip-joint, when it becomes inflamed and ceases to move: so when its serous covering is inflamed the vermicular movements of the intestines cease and at some period or other all people with peritonitis cease to empty flatus and fumes out of their bowels, meanwhile the bacteria in the intestines continue their gas manufacture and the abdomen begins to distend. Hence many peritoneal abscesses contain not only pus but a large amount of gas also, and afford a resonance which may mislead those who are not acquainted with the cause.

Much rigidity of the abdomen means very marked and extensive peritonitis which is more than often beyond the reach of operation and the surgeon should not wait for such a forbidding sign as rigidity.

The point of the abdomen lying over an inflamed appendix (for instance) is immobile and this immobility very often points off hand to the seat of the septic peritonitis. Mr. GARRIE SMITH calls attention to the extreme stillness and silence of the abdomen. In mechanical obstruction or in colic the intestines are 'on the move' and the stethoscope reveals all sorts of noises in them; but in peritonitis the coils of intestines never move and not a sound is heard; because as soon as the intestines become inflamed they are perfectly still.

The abdominal pains are of extreme importance, because they are the guide to the operations but they are pains which the surgeon can himself elicit. Patients nearly always refer the pain to the umbilicus, but pressure upon the linea semilunaris elicits very acute pain. Supposing pain cannot be detected over the linea a finger passed into the rectum and pushed up beyond the bladder is bound to elicit a shrill cry of agony, and disclose an indurated or elastic swelling.

In the female vaginal examination gives useful information. The uterus may be fixed or there may be extreme tenderness in DOUGLAS' pouch. In very many of my cases of acute septic peritonitis the sepsis was traced to the Fallopian tubes, and pelvic abscesses of acute peritonitis often tend to bulge not only in DOUGLAS' pouch but also underneath the left linea semilunaris.

In boys the appendix frequently lies in such a way that while its root is in the iliac fossa its free end hangs over into the pelvis so that the pus collects in there. Acute pain on micturition or an attack of retention of urine is often associated with this pelvic type of appendicitis but the doubt is easily removed by drawing off the water and seeing if the swelling still persists.

It is easy to understand that you may elicit no pain or tenderness in the front part of the abdomen, but

very considerable tenderness and pain would be evident upon vaginal or rectal examination.

If a patient has passed a motion he has not got intestinal obstruction, but people with peritonitis sometimes pass a little flatus, which ought not to mislead you. In such a case it is wisest to clear up the diagnosis by ordering an enema of soap and water with castor oil and turpentine, which, if efficiently administered, ought to make the bowels act or bring away flatus; but if it fail to do so, do not hesitate to operate as soon as you possibly can. The risk of opening the abdomen, under modern methods, (fatality about 1 in 500) is a very minor one compared to the risk of leaving such cases alone, as they almost to a certainty die on the fifth day. The chief risk from laparotomy, if care were not sufficiently exercised, would be a ventral hernia.

I know some cases of chronic localised septic peritonitis do go for a long time and perhaps recover, but they do not come within my range this evening; I am dealing with those showing an exceedingly rapid pulse, a distended abdomen, constant vomiting and intestinal obstruction.

Supposing that the diagnosis of acute septic peritonitis had been arrived at, either local or diffuse, some attempt should be made to ascertain the source of infection of the peritoneum; though for operative purposes it is sufficiently practical to know that you have to deal with a case above or below the umbilicus.

A great deal has to be done before the operation is undertaken at all for though the operation is important it is a really only a part of the treatment and the real struggle begins after the operation is over. Nearly all of those who die succumb to some heart failure; the pulse runs up from 100 to 120 or 140 for a few hours and then suddenly ceases.

One of the great troubles with the anaesthetist is to keep the heart going during the operation, on which account I give the patient 1-20 grain of strychnine before, 1-50 during and another 1-50 grain after the operation.

To avoid shock it is very important to have the room hot, and, if possible, place the patient upon a hot-water bed or surround him (her) with hot-water bottles during the operation, shortly before which fill his (her) rectum full of hot brandy and water.

It is desirable, sometimes, to wash the stomach out lest the patient may vomit up all sorts of material during his anaesthesia, and run the risk of getting the contents of his stomach into his air passages.

In reference to the operation one of the first cares is to have all the appliances very hot and maintain the sponges and lotions at a temperature of 110°. The patient having been anaesthetized, the field of operation rendered aseptic, the routine procedure in very acute localised peritonitis is to cut down and open the abscess at once, and, if there are not many adhesions, remove a gangrenous appendix and concretions, but not to waste time looking for the appendix or tubes amongst a great many adhesions. Some surgeons confine their attention to cleansing out the abscess cavity with swabs or sponges. This may be well enough if there is a single abscess with well-marked walls; but in most of the acute fulminating cases there is not a distinct abscess wall. The other day I opened and

washed out an abscess under the linea semilunaris; but in moving the intestines aside I came upon a second and further on a third collection of pus, and washed them out, I also irrigate these abscesses freely and treat an abscess inside the peritoneal cavity just as I would one in a person's arm. For washing out the abdomen I have used comparatively strong solutions of antiseptics and I choose the bichloride of mercury in preference, because it is one of the strongest and it does not combine with anything in the abdomen and probably any that is put in comes out again. These patients do not get mercurial poisoning. In my earlier cases—which have been my worst—I have freely let gas out of the intestines with a fine trocar as well as made cuts into the intestines to let out the faeces, and strange as it may seem these cases have got better while others have not. If you cut the intestinal wall while you have it in sight it is a perfectly innocuous proceeding; but it is bad surgery to return intestines (into the abdomen) which are distended with flatus. I think india-rubber tubes are the most comfortable for drainage purposes and if a glass drain is used I think it should be replaced at the end of 48 hours by an india-rubber tube which is gradually lessened.

In many cases the struggle only begins after the operation is over and it becomes necessary to flog the heart along for a few days, strychnine and brandy or ether and so forth will have to be given to keep the heart going. In other cases any attempt by the mouth causes and aggravates vomiting, doing more and more harm to the heart and killing the patient. In these cases rectal feeding is all important. First wash the rectum out with tepid water and as these patients—are usually very thirsty—one of their greatest troubles, leave half a pint of tepid water in the rectum after it has been washed out. This is absorbed and goes to relieve the patients' thirst. After twenty minutes a four ounce enema of good milk and meat essence thoroughly peptonised, should be put in. A little brandy may be used with these enemata; but the brandy must be good as bad brandy so irritates the rectum as to make it refuse to hold enema. A good plan is to add 5 drops of laudanum to cause the enema being retained.

I was taught that after strangulated hernia you must give opium to keep the intestines quiet and that in peritonitis you must do nothing which will make the intestines stir. He would be a very clever man who could make the intestines stir in a case of peritonitis and cannot think that in a case like this when it becomes a question of whether you will try to relieve the abdominal distension which is most difficult to get over and makes or mars a case—or will let the patient die without doing anything, that a dose of calomel makes much difference. If you are afraid of drugs by the mouth a great deal can be done by enemata. I am in the habit of giving patients calomel and following that up by enemata, by far the best of which for removing flatus is a soap and water enema with half an ounce (each) of castor oil and turpentine added to it, and to avoid sickness or faintness after the enema a dose of strychnine may be given.

As every now and then cases will go on quite well for several days and then will have a recrudescence, patients

require a good deal of watching to know when a relapse is coming on. If the abdominal distension is never quite gone and the temperature has never quite fallen to normal, the pulse inevitably points out that something is wrong. I had a lady patient with septic peritonitis due to perforation of the appendix. Her pulse and temperature fell till the tenth day when she had a rigor and the pulse ran up to 120. She began to be a little sick and the lower part of her abdomen was a little tender while she had a collection of fluid in Douglas' pouch where I afterwards opened a stinking abscess, when her pulse began to slow down and she convalesced.

There are cases in which a second operation may save the patients' life. Some of my cases were of the most desperate kind—moribund, in fact. In some the abdomen was distended, the pulse unobtainable at the wrist and the feet and hands cold, and yet I have operated upon them, let out pus, perhaps removed the appendix, washed out the abdomen, and have seen such cases recover even though they had gone so far that it was hard to think they had 'got a chance' and any body of common sense might have questioned the sanity of operating at such a stage.

I do not think a surgeon ought to think of himself altogether when he is dealing with such cases and my experiences have taught me to be afraid to say "No one has a chance of getting better from septic peritonitis." After her confinement a lady had sepsis of the uterus and Fallopian tubes—some one called it puerperal fever—and improving within a month under antistreptococcal serum was allowed to get up. That afternoon she had vomiting, diarrhoea and violent pain in the abdomen. At night her hands and feet became cold, she vomited continuously, had a distended abdomen and diarrhoea and she felt sure she was going to die. Obviously she was, but as I did not think it right to let her die with her abdomen full of pus I put her on a little truckle bed. I set on a stool on one side while my assistant Mr. WADD knelt on the other, and Dr. MALCOLM gave the anæsthetic. There was an abscess in the left Fallopian tube through a hole in which pus was spurting and the peritoneum was injected, inflamed and contained a large quantity of pus. At this stage MALCOLM thought she was dead, but thinking it a pity to let her die like that I injected her (hypodermically) with brandy till I thought she moved, when in spite of Dr. MALCOLM'S "she is still too bad to go on," I poured a big basin of hot bichloride lotion—1 in 4000, into her abdomen, pulled the abscess up to the wound, opened it and fixed a drain. The wound was rapidly sutured up after which we cut her clothing off, covered her with blankets and surrounding her with hot bottles, began to inject strychnine and brandy again. She had a dreadful bout of vomiting; but she got quite well and I met her in the street the other day.

Since 1894 I have had 27 desperately bad cases of peritonitis—i.e., in persons who were dying and apparently passed hope. Of these 13 got well after operation while 14 died; but of these latter one died on the operating table where I need not have put him were it not that I did not think it right to let him die with his abdomen full of pus. In another case there was a perforating ulcer of the duodenum in a person who was actually moribund

with the abdomen in a young lady, got a very good result, but not in my hands : So that apparently each person in desperate straits has a 50% per cent. chance of recovery, and I may say in conclusion that if we approach this subject with unprejudiced minds, very much progress might be made in the early diagnosis of cases, also in their surgical treatment.

NOTES ON THE HEATON METHODS OF TREATING HERNIA.

By THOMAS H. MANLEY, M.D.

New York.

It will be noted from the kindly reference to my work, by Professor WAGNER, that some space is devoted to HEATON and his method of treating hernia, by the subcutaneous injections of astringents, but it would be remembered, that though HEATON was a regularly educated physician, he kept his career a secret for years, and his methods in many particulars were those of a quack ; but he made a profound study of hernial maladies and cured, or at least made the afflicted believe they were, by accessory measures, which stamped him as a master of his art.

HEATON selected his cases with consummate tact, and studied the patient as well as his infirmity. Realizing that the etiological foundation of hernia is constitutional, he utilized hygiene and psychologic measures with singular advantage. In the obese, he purged and reduced the diet. He confined many cases to bed and maintained regulated pressure over the bulging mass.

For years, he kept the composition of his "fluid," a profound secret ; but these mysterious drops though ostensibly the magic remedy, were but an incident in the treatment. He made it quite an invariable rule, to insist on the continuous use of the truss after cure (?)

THE METHODS OF HERNIA SPECIALISTS.

We are often asked, if there is anything essentially different in the treatment of hernia, as employed by advertising specialists and the methods known to the profession generally.

So blatant are the specialists in their pretensions and so boastful in their assertions of rapid cure, that the conscientious physician becomes anxious to know if there is any better method that he can employ in justice to his patients.

We are, therefore, much gratified to be able to place before our readers the following article written by Prof. WM. F. WAGNER, who has taken pains to inform himself upon this subject, and whose opinion is valuable and decisive :

The inner history of the vast majority of the successful nostrums vendued to the public would show that they are composed of ingredients perfectly well known to the medical profession. These keen-witted gentlemen get hold of a well designed prescription, perhaps originally put together by one of the great men of the profession, and exploit it with all the tremendous power of printer's ink. When the formula is made known every one is surprised to find that the ingredients are those in every day use. A highly successful advertiser once told me he proposed to put on the market a series of "best remedies" for every disease, for the use of physicians. "WHY you keep the

best remedy," I asked. "Certainly," he replied, "the best remedy is often the one most commonly used, but if the doctor knows, for instance, that we are giving him salicylates for rheumatism he will not buy it ; whereas, if we disguise it so that he does not recognize it, he will use it forever."

Some time ago my attention was attracted to the glaring posters announcing the merits of a new and wonderful method of treating hernia, producing a radical cure without the use of knife or ligature, etc. The company had opened its offices in this city, as well as in several others. Desirous of ascertaining whether there was really a new discovery at the bottom of the scheme, I sent one of my assistants to interview the advertisers. He found them occupying a nicely furnished suite of offices in one of our prominent office buildings. All the appointments were quiet, in good taste, such as would probably impress the visitor favorably. None of those, waiting in the reception room, had the appearance of belonging to the class who could pay the charges of the company. When his turn came, our representative was ushered into the doctor's office. The ostensible object of the visit was stated ; an uncle of the visitor was affected with hernia. The doctor would not say whether the case could be cured until he had had an opportunity to examine it personally. Not all cases were suited to this method of treatment ; in fact a careful selection was made and only such cases were accepted as he felt so confident of curing that he was willing to guarantee that happy result. In such a case the money could be deposited in a bank, subject to the terms of the guarantee ; in case of failure to be returned to the patient, less the costs of drugs, apparatus, etc., which had been employed in the treatment of the case. This deduction was left indeterminate, and could of course, be made large or small at the discretion of the company. My assistant was unable to secure a copy of the guarantee, and I am therefore unable to say whether it really guaranteed anything at all. I doubt if one of these advertising concerns puts out a guarantee that really binds it to anything whatever ; and while people have sued to recover their money under it, I have never known a case in which any money was recovered. In this I do not refer to the company under discussion.

The cost of treatment varied from \$50 to \$500, according to the case ; and the doctor very wisely declined to commit himself more definitely until he had an opportunity to "size up" his customer.

My representative inquired what was the nature of the treatment, whether any cutting were done, what danger to life or as to permanent disability was involved, and what was the chance of success. To this the doctor replied that no cutting whatever was done in any case accepted by them, that no danger to life or disability was incurred, and that they expected to cure every case accepted by them, and actually did cure about 97 per cent. A process was employed by which the tissues covering the hernial aperture were condensed into a substance *tougher than leather*. The cure would be aided by the use of a special truss of their own invention, for a longer or shorter period.

The "leather-like" consistence imparted to the tissues

brings us at once to HEATON's method of injecting a preparation of oak bark.

Our readers will see that there is here no new discovery but that these people have simply appropriated HEATON's method, which is perfectly well known to every surgeon, and have palmed it off upon the public as something of marvelous efficiency, the secret of which is known only to themselves. There is no special secret about the method, and no special choice as to the fluid to be employed. Any agent that will cause the exudation of coagulable lymph in and around the canal, if aseptic and employed with aseptic precautions, will accomplish the object; HEATON's formula may be used until experience has suggested a better one.

The opinion of most surgeons is that the method has a very limited application. MANLEY, in his really valuable book on hernia, has this to say of the merits of the injection method:—"Warren injected tincture of iodine, sprayed along the interior of the empty, elongated neck, or into the walls of it, or just outside, into the interspace. GAY gave this mode a thorough trial in eighteen cases; with five cures, eight benefited, and five failures." But HEATON appears to have had better success, for MANLEY says: "Little wonder that he was lionized, for those who came to him with large, old, incoercible hernias, for which the most eminent surgeons could offer nothing better than a stiff truss, left HEATON cured." HEATON insisted that the four symptoms of inflammation, heat, pain, redness, and swelling, must not be caused, but simply that grade of irritation that induces the exudation of lymph. MANLEY limits its use to indirect inguinal hernias, of small volume when the sac and contents can be wholly returned. He lays great stress upon absolute rest for a week or more after the operation, with low diet; but the miracle-mongers state that their treatment does not interfere with the patient's going to his business. It is scarcely fair to judge of HEATON's method by the results obtained by injecting some other fluid, like iodine, and disregarding the precautions upon which he insisted. He also required a truss to be worn for some time after the operation. It would seem that up to the present nothing better than HEATON's original method has been devised by the regular profession or by the advertisers, and that there is more value in it than has been generally admitted.—Secret Nostrums and Systems.

THE INCUBATION PERIOD OF MALARIA EXPERIMENTALLY LENGTHENED.

ORLÉ and SANTORINI by rendering animals somewhat immune with malarial parasites, and by taking their serum and injecting it into patients before inoculation, have been able to delay the period of incubation of the parasites from an average of thirteen days to an average of twenty-five days; that is to say, the incubation period has been doubled. In autumnal fever the incubation period has been found to range from two to five days, the mean being three days. Men who were treated with serum of immunised animals, and afterward infected with malarial poison, were found to have an incubation period ranging from six to seventeen days, but the investigators were not able to prevent altogether the infection by this method of treatment even in a single case.—*Med. News.*

ILLUSTRATIVE CASES OF SEVERE CORNEAL ULCERATION AND ABSCESS.

By WM. HUNTLY, M.A., M.D., F.R.C.
Nusserebad.

THE readers of the *Record* must have enjoyed the comprehensive lectures of Dr. CALES on corneal affections, and the following five cases will serve to illustrate the subject in a practical way.

It may be laid down to begin with that corneal ulceration and abscess will have made some progress before the average native patient thinks of resorting to western treatment. Anything from a neem leaf or two, or a peacock's feather, up to a general circumambulation of the various presiding deities in the neighbourhood will be tried; I remember meeting a villager with an anterior synchia and leucoma carrying a young goat as a gift for the removal of the disease. When all or most things have been tried in vain, they present themselves with doubting faith to be treated by western methods.

The chances are that the case is seen some time after perforation, when the prolapse is well established and the patient has been suffering agonising pain in the eye and forehead.

Five different cases came into my hands recently, and the following brief notes may help some of your readers to save eyes in a like condition.

Case I.—Sent from a neighbouring town. Left eye with perforation and prolapse near the centre but below the horizontal meridian of the cornea.

Cocaine was instilled, a Graefe was passed through the prolapse on the side near the centre and then the prolapse was seized with nictomy forceps, and the iris pulled out until sufficient had come out to prevent there being enough left to prolapse a second time. This whole portion was excised and a pad and bandage applied. Some days later as the centre of the pupil was interfered with by an old leucomatous patch, iridectomy was performed in the upper and inner aspect of the cornea, and the result to the patient was splendid.

Case II.—This case came when the perforation was only beginning, and in this case an incision with a Graefe followed by ordinary treatment saved the eye.

Case III.—Pain drove this patient to the hospital. Intense pericorneal injection and general conjunctival inflammation was seen on opening the lids of the right eye. Towards the lower and right side of the cornea there was extensive infiltration and the cornea at this point was somewhat raised. The excessive pain was put down as due to the tension caused by the suppurative process going on in the cornea. As the knife was passed through the layers of the cornea, a tiny jet of purulent fluid rose from the incision. The relief to the pain was soon felt and gradually the abscess cavity threw out a small slough and filled up.

Case IV.—This case came to hand only two days after case three. It looked similar to case three and the differences were such as to be better appreciated by a compari-

The infiltration, redness, and pain were still. Inflammation however there was some thickening of the mucous and some pus in the anterior chamber.

The cornea was incised and a small necrosed portion extracted. The cautery was applied to the indurated portions of the infiltration near the lower border of the cornea. On the following morning the hypopyon had disappeared and the recovery went on uninterruptedly.

Case V—This was perhaps the most interesting case of the series. When the patient presented himself he had (I) a perforation and prolapse in the upper portion of (II) a large ragged phagedenic ulcer situated on the nasal aspect of the cornea, and (III) added to this there was hypopyon.

The patient was immediately put on the operating table, the ulcer was incised a little to get a firm grip of the prolapse with the iridectomy forceps and a large bit of the iris drawn out and excised. The cautery was then used to destroy the ragged and infective edges of the ulcer. Hypopyon soon disappeared, the ulcer has all but filled up and the patient, an intelligent man, knows well that his eye has been saved to him.

A CASE ILLUSTRATING THE DIAGNOSIS OF PYELITIS*

By JOHN SMYTH, M.D., SURGEON-MAJOR, I. M. S. Mysore.

ALTHOUGH the Hunterian Lectures for this year are by one of the masters of our art, and are at once a veritable storehouse of sound advice and a brilliant record of their author's work, I may yet be permitted to draw attention to what has appeared to me to be a defect.

In the technique for the operation of exploring the kidney and ureter (*British Medical Journal*, 23rd April, p. 1068) the author seems to throw cold water on the examination of bladder by electric light "It is rarely needful or helpful, and as a rule causes an unnecessary waste of time." Later on he refers to the difficulty of deciding which kidney is affected in certain cases of calculous anuria, and states that "the cystoscope is quite unnecessary in those cases." At p. 939 (9th April) he quotes a case in which his patient was passing muco-pus, but in which he was not certain which was the affected kidney; so he cut down on the wrong one. It appears to me the cystoscope would have prevented such a serious procedure as this. The following case from my own practice is in point:

A. B., about 50 years old, had been passing muco-pus and irrigating his bladder for about five years before I saw him, his medical advisers believing he had cystitis. What struck me at once during my examination of him was his statement:—"I declare I have not, nor have I ever had, pain." So it struck me that the pus was, at any rate, not cystic in origin. There was no tenderness nor enlargement of the kidneys. But I examined him with the cystoscope, and saw the pus pouring from the left ureter like thick custard. I was then obliged to leave the station, so I sent my patient home and Mr. H.

Fenwick removed the catheter from the left kidney. I may add that I tried, but failed, to make out the stone with an X-ray apparatus although the coil gave a 14-inch spark.

In regard to the waste of time which Mr. Monks refers to in connection with electric endoscopy, it would appear that the time required must vary greatly; but in the case I have quoted it only took about two minutes, no anæsthetic being necessary, and I do not recollect Mr. H. FENWICK ever spending more than five minutes over the actual electrical examination.

REPORT ON A CASE OF GUNSHOT WOUND OF THROAT RECEIVED IN ACTION IN TIRAH: RECOVERY.*

By MAJOR W. C. T. POOLE, M.B., F.R.C.S.I., R.A.M.C.
British General Hospital (No. 3), Nowshera, Punjab, India.

SERGEANT-DRUMMER S. M., age 33, eighteen years' service, 1st Battalion Northampton Regiment, was wounded in the neck on 12th December, 1897, whilst marching to the relief of Saraghari. The bullet entered the right side of the neck on a level with the inner end of the right clavicle, and came out on the opposite side on a level with the inner end of the left clavicle, partially severing the trachea as it passed. The wound on the right side of the neck was small, whereas that on the left side was large and exposed some of the large blood vessels of the neck, and from the general appearance of the wound the projectile appears to have been a Martini Henry bullet.

He was admitted into No. 3 British General Hospital, Nowshera, on 25th December 1897, thirteen days after the infliction of the injury. On arrival he was in a very critical state, the wounds were in a sloughing condition, septic pneumonia was threatening, his breath was fetid, and he was unable to partake of nourishment by the mouth.

Treatment.—(a) Dietetic: Rectal alimentation for about one week, afterwards small quantities of milk and chicken broth by the mouth. (b) Surgical: Inhalations of eucalyptus oil to cleanse the inside of the throat. Local applications of tinct. benzoin co., with an outward application of borie lint and wool.

He made a perfect recovery, and was discharged from hospital invalided to Netley on February 16th, 1898, 65 days after admission, and was able to partake of solid food before he left. It was highly satisfactory to note the rapidity with which the healing process responded to treatment.

Indian Medical Record.

15th August 1898.

THE SERUM TREATMENT OF INFECTIOUS DISEASE. IS IT BASED UPON SOUND PREMISES?

It is in the serum treatment of disease that the bacteriological developments of the present day find their highest expression; it is the ultimate, and most important result of countless investigations and of much patient labour and careful research.

Its evolution has been gradual, the data upon which it rests have been almost universally accepted as facts, and the inferences drawn from them have appeared to be almost unassailable.

Those who read the articles appearing at present in this journal by Dr. HEDDERS on the "Serum Therapie of Traumatic Tetanus," will see that the beneficial results confidently expected and prophesied from this new treatment are practically unlimited. By many shrewd observers it seems to be regarded as the modern form of the Elixir Vitæ.

Since the introduction of the treatment of diphtheria and traumatic tetanus by antitoxic serums in Berlin in 1891, an immense impulse has been given to this new departure in therapeutics, and already most of the infectious diseases have been experimented upon.

As to the good results that have already accrued there are many to bear witness. Still it is to be remembered, that even with respect to diphtheria, the disease which has led to the largest accumulation of experience, competent observers are to be found who regard the question as at least unproven.

A notable sceptic regarding the success of sero-therapy in diphtheria is Dr. LENNOX BROWN of London and with him we have M. KASSOWITZ of Vienna, whose remarks on the subject will be found in another part of this issue.

It is however no part of our present intention to enter into this part of the question, time alone can make the truth clear, at the same time we would direct attention to the remarks of M. KASSOWITZ wherein are exposed many of the fallacies which tend to vitiate a large proportion of the statistics relating to the success of the treatment of diphtheria by antitoxic serum.

We have to deal with another matter. It appears to have been very generally overlooked that the result of certain experiments which have been published lately in France, is to shake the structure of serum therapy to its foundations.

These experiments are simple and unequivocal and it is impossible to deny their importance or their far reaching effects.

Before detailing them it may be as well to briefly consider the rationale of serum therapy.

The fascinating and perplexing study of immunity may be said to be the parent stock from which serum therapy springs.

It has long been a matter of common knowledge that one attack of an infectious disease gives to the survivor

an almost invincible defence against another. The explanation of this phenomenon has been eagerly sought. For a long time we had to be content with the theory of the exhaustion of the soil, but we can now laugh heartily at the platitudes and analogies which were thrust upon us to make us believe that the seeds of disease acted upon our bodies as the growth of plants does, or was said to do, upon the soil; that the disease used up all the special material that was necessary for its existence, that it then died out and could consequently never again take root, flourish in such an exhausted medium.

A new direction was given to the speculations of investigators by the discovery that the blood itself possessed bacterioid powers, that is, that innate in the body itself was the power of grappling with, and often destroying the introduced poisons of infectious diseases.

The fact that different animals are susceptible to the different infectious diseases in different degrees, provided an almost unlimited amount of material for experiments upon these lines.

It was soon made evident that this bacterioid power could be produced in an animal that did not naturally possess it, this was of course an immense step.

A susceptible animal was taken, at first very small, then gradually increasing quantities of the specific bacilli of the disease were introduced into the system until at length the animal emerged immune. Evidently a certain material had been produced in the body of the animal which was antagonistic to the specific poison of the disease experimented on.

The final step was to show that if blood serum was taken from this animal and injected into another of the same species a like immunity was conferred upon it.

In these few facts we have the whole mystery of the serum treatment of infectious disease.

Take the case of diphtheria, large amounts of the specific bacillus of diphtheria are cultivated, they are then injected intravenously into a horse. When this has been repeated several times the horse is bled, his blood serum is carefully filtered, it possesses the power of neutralising the diphtheria bacillus and when injected into the human being in suitable doses, is believed to cure the disease and also to give immunity against it.

The vague terms, toxins and antitoxins, are used to designate the specific bacilli and their products, and the antagonistic material that is created in the body respectively, the present state of our ignorance regarding the nature and mode of action of these products renders any mere intelligible or explicit nomenclature impossible.

Such is of necessity an incomplete and bald outline of the fabric of serum therapy, but there are other important and closely associated matters to be dealt with.

We are to believe that every infectious disease has its own special specific micro-organism, and that such micro-organism develops its own special and specific toxin and causes to be produced its own specific antitoxin; that is, a toxin and an antitoxin peculiar to itself alone, and which cannot by any possible means be produced either by any other micro-organism, or by any other means whatever.

To admit that such is not the case is to rob serum therapy of its fundamental data, and to reduce the conclu-

of the reaction is derived from a condition of almost complete immunity to an ill defined and unspecified hypothesis.

The question of 'specificness' is all important, it is the heart of the matter, yet it is this very fact of specificness which the researches we allude to have completely overthrown.

Regarding the specific nature of the pathogenic bacilli and their products, we may refer to the very remarkable and interesting reaction, known as *PREISSER'S* reaction, which ever since its discovery a very few years ago has attracted a large amount of attention and appears to be strongly corroborative both of the specific nature of bacilli and their products, and of the accuracy of the conclusions leading up to serum therapy.

PREISSER'S reaction is as follows, if an animal is artificially rendered immune to a certain disease and then some of its blood serum taken and added to a living cultivation, in broth, of the specific bacillus of that disease, the result is that the bacilli are affected in a curious and distinctive manner, from being evenly distributed throughout the broth, and in active motion, if motile, they begin to collect together, and as it were to stick together, in groups or clusters, to lose all activity and to be apparently destroyed.

This is supposed to be due to what is termed the agglutinating material in the serum, and it is called the agglutinative reaction.

One bacillus will not react in this way to products produced in the animal by another bacillus.

The application of *PREISSER'S* reaction has been widely extended, it is evident that in it we have a means of detecting and differentiating between different pathogenic bacilli, it is therefore an exact test for an unknown variety of bacillus.

Further, it is also a test for the disease, and *WIDAL'S* application of the method to typhoid fever has attracted an unprecedented amount of attention over the whole world; in this case the serum of the infected individual is taken and added to a fresh cultivation of the typhoid bacillus, if it exercises this specific agglutinating action the disease is declared to be Typhoid fever.

This is a most important and practical development of *PREISSER'S* discovery, and the accuracy of its results in general have been largely vouched for.

The nature and the exact import of this reaction in typhoid fever is still a subject of discussion. *M. GOUSSER* holds it to be a reaction of immunity. *WIDAL* considers that it has nothing to do with immunity, but that it is primarily a reaction of the period of infection. "The agglutinative reaction," he says, "is often more intense at the beginning of the disease than at its height or at its decline, it diminishes and frequently disappears in man from the first period of convalescence, that is to say when immunity is most perfect."

Apparently *M. PAUL COMBES* has arrived at much the same conclusion from his experiments, he calls it a reaction of defence, a defensive action on the part of the organism against the invading poison.

It is however well known that *WIDAL'S* reaction is not

specific and accurate as it should be on the theory of the infallible specificness of the bacilli and their products; the reaction has frequently occurred in diseases other than typhoid, and in untypical typhoid it has been proved to be sometimes absent.

Some illumination is given to this part of the subject by the researches of *M. BACQ* which formed the thesis of a communication made to the Belgian Academy of medicine, by *M. VAULAIR*, which is given in *La Semaine Medicale*, 4th June 1898.

M. BACQ'S work he tells us "comprises a series of researches undertaken with the object of settling definitely the value of serum-reaction. In a preliminary memoir (*La Semaine Medicale* p. 15. 1897) the author has already made known a number of facts which tend to show that this reaction is not specific. His further researches confirm his earlier conclusions in every particular.

The majority of writers look upon the agglutination of the typhoid bacillus (bacillus d'Erberth) as a specific phenomenon."

"*M. BACQ* obtained agglutinating material from the following different sources; definite chemical substances as formaline or fuchsin, serum from typhoid patients, serum from an animal experimentally injected, or vaccinated. His object was to see if these substances acted only on the typhoid bacillus."

"By plate cultivation he isolated a large number of varieties of bacilli belonging to the groups of coli bacilli."

On these isolated varieties he tried the effects of formaline, nearly one third gave the agglutinative reaction to an equal extent with an authentic sample of typhoid bacilli used as a control experiment."

"He then collected several of the varieties of coli bacilli which gave different types of agglutination with formaline, and submitted them to the action of typhoid serum, and of serum obtained in the course of experimental vaccination, they agglutinated readily."

"From these facts he naturally concludes that far from being a criterion for the differentiation between typhoid and coli bacilli, agglutination is only of secondary importance."

These experiments show that the agglutinative reaction is useless in distinguishing between typhoid bacilli and coli bacilli, and thus throw considerable doubt upon the theory of specificness; considering however the close resemblance between these two varieties, and the various theories held concerning them, this may not appear to entirely upset the general truth of the doctrine, and to many it may appear quite unimportant and capable of explanation.

This is not the case however with the following researches which are the ones we have previously alluded to, and in the first place to show the hold that the specific doctrine has taken and the importance attached to it we will give a very neat and concise definition of it which has been formulated by *NICOLLE*. He says the agglutinative power is the signature of the passage into the organism of the specifically agglutinated substance."

11. *Answer to the following question in the French Academy of Science, on the 1st May last.* "In my note of the 16th May 1898, I have shown that the blood serum of the goat acquired the power of agglutinating rapidly and completely Koch's bacillus suspended in a homogeneous emulsion, when the animal had received a series of subcutaneous injections of tuberculin, or of the bacilli in a more or less virulent state. I have also shown that the blood of the goat and rabbit could be rapidly endowed with this property by means of a few injections.

But I have found out that the blood of the goat acquires similar properties under the influence of repeated injections of Eucalyptol, of Guaiacol, of Creasote and of the liquid of Mialhe (corrosive sublimate), the last being injected in the natural state, the others preferably mixed with olive oil.

The goats from which I obtained the serum which agglutinated Koch's bacillus had been for a long time under the influence of these substances.

The injections were graduated, stopped and continued so as to preserve the animal in as good a state of health as possible.

On the 1st April 1898, I bled four of the goats and obtained four samples of serum, a comparative test was made between these serums, and the serum of goats subjected to tuberculin and to Koch's bacillus in the proportion of $\frac{1}{10}$, all possessed the agglutinating power.

The goats were bled again on the 20th May 1898, and the samples then obtained possessed the same agglutinating power as the others.

An equal volume of these serums agglutinate slightly less actively than the serum derived from goat subjected to tuberculin and to Koch's bacillus.

The difference, however, is very slight in the case of the serum derived from animals injected with Mialhe's liquid.

The presence of the agglutinating material in the blood is due to a reaction of the living organism produced by the action of these four chemical substances, for no agglutination is produced by the addition, to emulsions of Koch's bacillus, of $\frac{1}{10}$ or $\frac{1}{2}$ part of saturated aqueous solutions of Eucalyptol, Guaiacol or Creasote, or of equal parts of Mialhe's liquid. It is evident then that the agglutinating power is created by chemical substances which do not themselves possess it.

The effect upon Koch's bacillus is identical with that produced by the agglutinating material provoked by the introduction of specific substances into the organism."

Here then we see that the agglutinating properties so long and fervently believed to be the specific production of pathogenic bacilli, can be produced equally well and apparently in the same way by several different chemical substances. This discovery at a blow removes the scientific veil from the face of serum therapy and reveals the unwelcome features of empiricism.

Answer all the comments and criticisms that the measures adopted by Government to keep the plague in check have called forth from time to time, and which have occupied a large portion of the various sections of the press; we do not remember that particular attention has been called to the strange and glaring anomaly of importing medical men and women and nurses, from England.

This action was unnecessary and unequal for, and must be condemned as a mistake in every way.

We would very much like to know the inner history of this move and the name of its inspirer. In the absence of this knowledge we can only assume that if not originally suggested by the Director-General of the Indian Medical Service it at least had his approval and sanction.

This, however, is a point upon which we can feel no degree of certainty, we know not what amount of influence the opinions of the Director-General have in the Councils of the Government, for all we know he may never have been asked, and the step may have been taken merely to pander to the wishes of some very superior individual who was quite incompetent to form an opinion of any value on the subject.

It is a pity that in things medical, the doctors are not allowed to run their own show, but the history of plague administration affords numerous examples of the reverse, and proves that whenever possible, the doctors are thrust on one side to make way for individuals in some more favoured service.

Is it said that it was necessary to import doctors and nurses from England, because none could be procured in India? Such a statement would be absolutely false, for they can be obtained in any number required.

Is it maintained that they were not as capable of dealing with plague as those freshly imported? This position can be shown to be as groundless as the other.

Let us first consider the Doctors that were imported.

We have never heard that any of those medical men and women who were sent out by the India Office were experts on plague, far indeed from this, we are not aware that any of them have ever seen a single case.

In the matter of experience then they have absolutely nothing to recommend them. They were sent out to tackle a disease that was unknown to them, and in the first place they had to become acquainted with it.

In this respect they had certainly no advantages over the Doctors who could have been obtained in India, while on the other hand they suffered from many disqualifications.

They were new to the country and untried to the climate, so that it might easily have been anticipated that they would more readily have become incapacitated through illness.

They were ignorant of the language, and therefore unable to communicate directly with those amongst whom their work chiefly lay. How they must have been handicapped by their deficiency in this respect is so obvious, that comment is unnecessary; to state the fact is enough.

They were unaccustomed to deal with coloured people, and every medical man will acknowledge the difference

that the only of the sick and the only of the sick-ness. In fact we have several times heard doctors remark that the first time they were called upon to treat a dark skinned person, whether Indian or African, they felt as much at sea as if they were investigating the disease of some strange animal.

But the disability, that will be acknowledged, by all who know anything, or have read anything about the natives of India, to be the greatest and to stand out in the highest relief, is that those selected, were totally unacquainted with the manners and customs, the thousand and one peculiarities and caste prejudices which distinguish and form as it were the life-blood of the people of India.

When we consider all these things, there can no longer be any room for wonder or surprise that difficulties should have arisen, that plague doctors should have been mobbed, camps destroyed, and turbulence and riots manifest everywhere.

As for the Nurses it is not necessary to say much, in all matters of inexperience and ignorance they were on a par with the Doctors; and let anyone ask the question of himself, how he would like if he were sick unto death, to be dependent for all his wants upon a person, an alien in every respect, foreign in aspect, colour, religion, language, instincts and thought, would he like to be nursed by such a one?

Who can wonder that the sick were unwilling to leave their homes and their friends to seek for treatment in the Government camps and hospitals?

There is however another aspect of the case, the financial one. The financial difficulties of the Indian Government is an ever verdant theme, like the poor, it is always with us, it has passed into a proverb. But if one were called upon to express an opinion on the subject from a study of its actions, one would easily be led to believe that the Government was suffering from nothing but a superabundance of wealth, that it was overburdened with affluence, and like a prodigal, was only anxious to squander it in all sorts of foolish ways.

Nurses could have been obtained in India for Rs. 80 to Rs. 100 a month, the imported nurses were given Rs. 200 to Rs. 300 with furnished quarters, free passages etc.

The imported doctors were engaged at Rs. 500 a month while there were men in India with British qualifications, and others with university degrees, willing to work for Rs. 200 to Rs. 300 a month.

All this extra expense was unnecessary and was certainly not justified by the superiority of the article secured.

Here in Calcutta at the present moment we are supporting a large staff of plague doctors and nurses who have nothing to do, and we are informed by the official spokesman of the Bengal Legislative Assembly, that the intention is to maintain this idle establishment until next cold weather, in case the plague should then become epidemic. This is foresight with a vengeance! But the soundness of the policy is another question, upon which we unhesitatingly pass an unfavourable opinion.

This action of the Government may be taken to imply

the gravest censure upon the Indian Government, upon every Indian College and Hospital, and as condemnatory of every state agency and agent of the Indian Medical Service, that it employs in the educational institutions of which it holds a monopoly.

It is a sad confession of failure that after all these years, and the vast sums spent upon education, that the Government is unable to find amongst all its graduates and diplomates a few sufficiently well qualified to be employed in plague work. Their own standard is not sufficiently high.

Something of this kind we have repeated over and over again *ad nauseam*, but to ears that have chosen to be deaf. We have urged and brought forward cogent reasons for the necessity of reform, without response; and we now view with complacency the Nemesis that has forced those in authority to place in our hands, weapons even stronger than any we have forged for ourselves.

Let it then be known once and for all, let it be proclaimed from the house tops! that the training and teaching of medical students and nurses in the Indian Universities and Government Colleges is a farce, that the medical education they receive is worthless, that the Government stamp they bear in their degrees and qualifications is base, it will not pass for current coin, that there is no employment, no future, no prospects, before the Indian graduate.

And all this the Government has tacitly admitted by having had recourse to the English market to provide themselves with a few Doctors, and Nurses even, to look after their plague cases.

It is in the saddest spirit that we see the Government of the country doing all it can to degrade its own students, and closing every door to the advancement of Indian Medicine. This last stroke is a deadly one and must bear heavily upon those who have the best interests of Government at heart.

We cannot think that the Director-General of the Indian Medical Service has any responsibility in this matter. He at least must be fully acquainted with the different teaching institutions throughout the country, he must be aware that competent men and women could have easily been found in any number for this work, and also that such nurses were actually being employed and giving every satisfaction, when they were dismissed to make way for the new arrivals.

If the Director-General with all this knowledge, still approved of the step, it merely clenches the argument, that the state of medical education in India is rotten, and urgently needs to be regenerated.

As for the Universities, who without any protest, permit such slights to be put upon their graduates, what can be said of them? They are dead or drugged, or huddled together in terrified silence like sparrows under the hovering hawk of officialism.

THE PRESENT POSITION OF THE THERAPY OF
TETANUS TETANUS.

IV.

5th February.—This morning the pulse is less frequent than yesterday, 120 in the minute. The patient feels very weak. The spasms are still as severe as they were during the night but they are less frequent, about every 4 to 5 minutes, opisthotonos is still present.

The trismus is not so severe during the spasm, and in the interval it is certainly less than yesterday.

Yesterday evening the teeth were clenched so tightly that no effort of the patient could separate them, this morning however the finger tip can be introduced between them.

Any attempt to swallow quickly induces spasm of the muscles of deglutition and respiration, and on this account the patient refuses to drink.

In addition to nutrient enemata, enemata of wine and water were twice administered, also of chloral, they were well retained.

Occasionally a fit of coughing occurs with an increased collection of phlegm, which the patient with great difficulty presses out between the teeth.

After the chloral he was quiet for several hours and appeared to slumber, the spasms grew less frequent, when the effect passed off. Tinct. Opil. was injected subcutaneously.

In the course of the afternoon there was no change in his condition. There was no aggravation, and no other muscles were affected, at 8 p. m. there was a sudden accession of spasm, with respiratory troubles and cyanosis of the face; no stridor, but spasm of the diaphragm is present. He rested for a short time after a hypodermic injection of morphia, by means of a raised pillow he was placed in a half sitting position and once again the breathing became easy. After about half-an-hour the spasm completely disappeared and the patient slumbered, he groans at each inspiration as if in pain, but says he has no pain when questioned.

As it was suspected that toxin was being conveyed into the system from the original lesion which had not been completely destroyed, I anaesthetised the wound with cocaine and thoroughly destroyed the tissues as far as the infiltration extended with the thermocautery.

This procedure was carried out, in the full knowledge of the patient without producing a single spasm. A lukewarm packing was then applied which brought on a profuse perspiration.

The patient remained quiet till about 12 o'clock when spasm came on again, and this time the opisthotonos was so severe that he was thrust off the raised pillow. To give relief Tincture opium was again injected, it produced no effect, and the breathing which was previously increasing became gurgling. Camphor oil was injected subcutaneously to stimulate the respiration, but the patient did not respond. I then endeavoured by carefully introducing the gag between the teeth to remove the phlegm from the mouth and throat. At every effort however such severe trismus came on that the gag though a strong one, was crushed flat.

In the hope that the phlegm might be better crushed through the teeth, at half past two when he was in extreme, I performed tracheotomy. He died however when the trachea was opened. Post-mortem the temperature rose to 102.5°F. Until a short time before death the pulse was strong and regular.

When the body was opened, small sub-endothelial haemorrhages were found, also haemorrhages beneath the bronchial mucous membrane; in the stomach and kidneys nothing worth mentioning was observed microscopically.

The foregoing case comes in the category of the most severe. We have seen that trismus appeared 5 days after a most trifling wound. Even before this facial paralysis had been noticed without however attracting much attention.

This combination makes the prognosis doubtful from the outset and was proof of a severe local infection. I thought therefore to follow Ross's instructions, for he lays special stress on the destruction of the primary lesion, and with every confidence examined the wounded part and the apparently sound tissue beyond, the examination of the preparations showed however that it was not sound. Nevertheless I had carefully cleaned out the wound with carbolic acid the effectiveness of which is universally acknowledged, and had swabbed it with the equally efficacious orthokresol, so that my mind was at ease.

The next day there was a rapid development and before the evening the case which had begun so mildly, assumed the distinctive characters of head tetanus with spasms of the muscles of deglutition and of the glottis.

The antitoxin which had been expected for some time then arrived, full of hope I injected the whole of it (there was only a single curative dose) intravenously. It was certainly stated in the directions which accompanied it from the HOCHSTETTER chemical works that, "In tetanus in men and in horses we recommend subcutaneous in place of intravenous injections, as we have reasons to believe that the intravenous injection of large quantities of the fluid drug is not always a reliable operation." Expressed thus we did not think that the caution was intended for, or was binding upon us, it appeared to be a precautionary step on the part of the authors to avoid accidents in unskillful hands, by which the whole treatment might fall into disrepute.

With the necessary precautions an intravenous injection is an absolutely harmless operation. Besides it was the same preparation that I had used before, with the exception that the one was dissolved at the Hochstet instead of our surgery, and after the three former intravenous injections I met with no unpleasant results in consequence of the mode of application.

I was also under the impression, from the literature of the subject, that the reason frequent large doses were required subcutaneously was because this method of application was employed.

I therefore as described injected the antitoxin intravenously.

The patient stood the small operation well and without any increase of the reflex spasms. The general reaction was however a severe one, after four hours the temperature rose to 103.6°F. while the pulse was 156, it fell however quickly and by the morning was again normal.

* By Von. Dr. A. Heidegger Heidelberg. Translated from *Munchener Medizinische Wochenschrift*.

Whether the severe reaction in the next case was not very strong, was the probable cause of the weakness that prevailed the next day, cannot be satisfactorily settled. In the previous cases an almost similar reaction resulted, yet was not followed by any unpleasant after consequences, in these cases however the patients were strong men. A certain amount of caution is clearly indicated.

Since in our case the antitoxin was applied very late, the method of intravenous injection appeared to be the quickest and most effectual way of getting a satisfactory result, besides the method was recommended in the directions which accompanied the earlier preparations.

Let us now consider what was the actual effect of the antitoxin? As in the previous cases, a contrast between the day and evening preceding the injection and the following morning shows us that the first effect was undoubtedly upon the trismus. It is true that the mouth could only be opened to 1 c.m., still the difference was sufficient to be noticed. And when in a case of such severity, undergoing rapid development, there is a sudden change for the better in the most important symptoms, we are bound to attribute it, not to chance, but to our treatment, if we have taken energetic measures; besides the spasms showed a slight improvement. I will not however advance this in evidence as the change might have occurred spontaneously.

Unfortunately the good effect did not continue. We had no antitoxin for a fresh injection and as it could not reach us, though telegraphed for, before the next morning, the only thing to be done was to support the patient's strength which was done by nutritive enemata, and to combat the complicated symptoms as was done by means of chloral, opium, and morphia, a further destruction of the local seat of lesion, and profuse perspiration induced by luke-warm packs.

These measures were however insufficient and death resulted as a consequence of an infection and intoxication of extraordinary severity.

The animals that were inoculated with the excised portion of skin all got tetanus, first, after 2 days the guinea-pig, then the mouse then the larger and finally the smaller rabbit. Tetanus bacilli were not isolated from the wound although cultivations were made according to BUCHNER's method (an agar agar plate culture heated for an hour in a water bath at a temperature of 176°F. to destroy other micro-organisms, and then a stab culture made in grape sugar and agar agar).

This case cannot affect our judgement regarding the effects of the antitoxin treatment, because the way in which it was applied was too faulty to allow it to have any weight. For it was first applied when the disease was at its height and then the dose was too small to produce a satisfactory result, and finally a second injection which was necessary to judge of its effects was impossible owing to the antitoxin not being at hand. There was only an incomplete application of the treatment and only a limited value can be attached to it. It will therefore have no effect upon our general conclusions regarding the antitoxin treatment. The question must now be put, what results can we actually expect from the antitoxin treatment?

What opinion do we hold as to its effects? Has it

limited its action in the tetanus which have been already observed? or has it the power of halting short the disease?

To answer these questions we must briefly consider the nature and manner of development of the tetanus intoxication. We know that between the infection and the first appearance of the symptoms there is a definite incubation stage, at the same time definite changes take place in the organism, which, as soon as they have reached the necessary degree of intensity in the organs affected appear as tetanus.

The changes are first the production of toxin at the primary lesion, then the absorption of the toxin by the blood and its dissemination through the body, and finally its effects upon the central organs, the medulla and the spinal cord. According to BRUNER and BARR these toxins, like the toxin of diphtheria have been isolated in the form of an amorphous body easily soluble in salt solution, they do not belong to the albuminoids proper.

These toxins now cause changes in the ganglionic cells of the spinal cord which lead to modifications of their excitability.

When these changes have advanced to a certain stage they become permanent and persist independently of the presence of the poison. (SAHL). Even when the primary lesion is destroyed the characteristic features of tetanus may persist unchanged. The length of time will depend upon the length of time that the poison has acted and upon its concentration.

GOLDSCHILDER and FLAIAN have in the last year demonstrated the anatomical appearances of these changes, by researches on tetanus poison in rabbits. They found characteristic nutritive changes in the motor cells of the anterior horns. These consist in enlargement and degeneration of the nuclei, enlargement and breaking up of NISSLE's granules, a sandy disintegration of NISSLE's cells corpuscles and a general enlargement of the nerve cells.

These morphological changes in the nerve cells are characteristic of tetanus poisoning, because they were constant, and were found invariably, and because they bear no resemblance to the changes brought about by other agencies, and further they have never been found by other observers.

The development of these changes was found by these observers to be very much influenced by the quantity and by the strength of the poison. The more concentrated the poison the more quickly the changes were induced, and the quicker they were induced the more quickly did the cells react and recover themselves.

The more gradually the poison was introduced, the more slowly the changes appeared, but they were also more permanent.

It is now clear that the antitoxin is able to neutralise and render innocuous to the body the toxins which is in the circulation, and which is continually being augmented by absorption from the injected lesion; but even as tuberculin has no power to remove in a moment the changes that have taken place in a tuberculous lung, the curative tetanus serum has no power to eradicate at once the alterations that have taken place in the ganglionic cells of the central nervous system.

And of this we have a proof in the experiments on animals. The authors referred to found that the tetanus

not antitoxin when injected into a vein had a decided effect upon the changes in the nerve cells; and especially that their progress and development was retarded. And that when the injection was given early and in large doses, the cells more quickly removed themselves. This effect of the antitoxin was equally manifest when it was injected before or at the same time as the toxin, and even when it was injected a considerable time afterwards.

The ganglionic cells require some time to recover from the above mentioned changes in the same way as every other organ in the body that is diseased. We cannot therefore expect that immediately, or even a very short time, after the injection, that the tetanus spasms especially if severe will disappear and that there will be no further recurrence, merely because with the disappearance of the toxin there is no further extension of the poisoning to other nerve cells.

Should however the production of antitoxin continue, the effect of the serum will be overcome.

If the production of poison ceases, cure will result in a short time, the least affected cells will quickly recover while those that are more effected will take longer.

This process of cure is a normal one and therefore there can be no question of cutting tetanus short.

Our clinical experiences are in harmony with the foregoing. In the first case the injection had no immediate effect, and it was only after several hours that a decided improvement declared itself gradually, however the toxin reassented itself and it was only when a second injection was given that a permanent good effect was obtained. There is no absolute proof that fresh toxin was formed and absorbed into the system after the first injection, but we are justified in concluding that the first dose injected was not sufficient to completely neutralise the poison.

Still it is open to conjecture that the infective lesion was in the first instance destroyed by the incision that was made after the second injection, and that this second injection had the effect of immunising the system against the production of fresh toxin that was going on.

In the second case, we noticed that there was first of all a check in the progress of the disease, then a slight improvement followed by a sudden aggravation. Here the complicated condition of the wound renders it very probable that there was an overwhelming supply of fresh toxin. Between the first and second injections the wound was thoroughly cleaned and disinfected for the second time. Perhaps this accounts for the great and permanent effect of the second injection, if we may presume that no fresh supply of toxin took place to the central nervous system.

In the third case we observed only a slight check, then an aggravation which continued to a fatal termination.

From these considerations can we be thoroughly contented with the results of our serum treatment of tetanus?

We do not deny that it is possible in many cases, especially of the milder type, to obtain a similar effect for the time being, by means of the symptomatic narcotic treatment; such indeed we have observed in our own cases.

But we must distinguish between obtaining the result by a drug which acts directly upon the symptoms and by one which affects them indirectly by destroying their

exciting cause. When we obtain the result by narcotic drugs are still of value for they act upon the spasms which are due to central changes, which the serum is powerless to influence directly.

Opium and calomel act in a similar way in infectious catarrh of the intestines.

Our results from the serum treatment of tetanus are particularly striking when we compare them with those obtained previously. Besides the first quoted case which was treated with opium, there were altogether 12 cases seen in the clinic since 1876 and all were fatal.

When finally we turn our attention to preventive treatment there is not much to be said. According to TIXON there is already a considerable series of observations on man, but in these cases the presence of tetanic infection could only be suspected from the nature of the wound.

It is difficult to draw conclusions as to the practical value of the results, because we are not in the position from clinical observation to foretell the advent of tetanus, there is no aura tetanica. Neither is it clear that it would be possible to persuade people suffering from a wound that was likely to produce tetanus to submit to serum injections on account of the general dislike to all surgical operations, even supposing that the price of the drug was much lowered. Yet *a priori* there is no reason why they should refuse the preventive inoculation which previous observations have shown to be harmless, any more than in the case of diphtheria, if it is shown to be practicable.

According to VAILLAND, experiments prove that protective inoculation is permanent if the succeeding injections are given subcutaneously, temporary, if deep in the muscular tissue.

He has given the following indications for preventive inoculations. (1). In all injuries where infection appears probable. (2). In veterinary operations when tetanus is frequent (castration. Injuries to the hoofs).

BEHRING also insists upon the necessity for preventive inoculations, and the HUCHER chemical works provides the following preparation for prophylactic injections.

A small flask for immunisation containing 2 cc.m. 10 fold = 20 Tet.—1.—E. 1 com. is sufficient for an injection and will give protection for four weeks when the presumed infection has only just taken place.

The same dose of 1 com. is sufficient as a prophylactic injection in the case of operations which are occasionally followed by tetanus. Should however the infection have taken place some time before, not less than 4 com. must be injected.

I will bring to an end my observations on the Therapie of Traumatic Tetanus and the position it occupies at the present day with the following conclusions.

1. Behring's antitoxic serum, according to the foregoing experiences, is undoubtedly an effective drug of a specific character in the treatment of traumatic tetanus, and should be administered in all cases of tetanus. It is best to give it at the earliest possible time.

2. The local treatment which consists in a complete destruction as possible of the primary lesion must not be omitted, for its neglect leads to a constant supply of toxins which is prejudicial to the effect of the antitoxin.

3. The symptomatic treatment with sedative drugs, narcotics etc., must go hand in hand with serum therapy, as it will be effective even when the latter fails.

4. The older methods for the elimination of the tetanus poison from the body must also not be neglected.

5. The preventive treatment deserves to be further investigated.

COMMENTS AND NEWS.

STATE DOCTORS AND PRIVATE PRACTICE.

The *Bengal Times*, the leading English newspaper of Eastern Bengal has the following cogent and well timed remarks on the above subject :—

"In a recent issue we published some remarks regarding State-paid doctors, and their immense advantage over non-official medical practitioners, who strive for a livelihood, without State aid as a fall-back. Our remarks seem to have been approved in quarters where it is felt that, open competition, however healthful, becomes a matter of serious concern, when it lies between two classes of medical rivals, unfairly handicapped. To enable him to enter upon competition, with a fair hope of success, a man must be unimpeded by obstructions, which are not easy to remove, nay, which, in many cases, are insuperable. Dr. A, who starts in private practice, feels that, with fair play allowed him, there is a career of usefulness and personal gain he may follow with credit; and in which, in a reasonable lapse of time, he may make an independence to solace his declining years. Settling to work with manly resolution and a hopeful heart, he finds, after a while that, he is supplanted everywhere, by men absolutely independent of casual fees, and with a sufficient monthly salary from Government to keep them comfortably, without an outside honorarium—or other independent help. They are well housed, well fed, well served, their equipages are smart, their dwellings well appointed, their salaries punctually paid. They can afford to dress suitably with their position, and to keep up a show that attracts a constituency, which is gradually nursed up at dinner parties and social functions, from which, most doctors in private practice find themselves excluded, because of their straitened circumstances, and their possible lack of introductions. They may be men of exceptional attainments, *au fait* with achievements in surgery and medicine, so brilliantly successful as to be almost incredible. They may be personally gifted with unusual, even enviable talents, but their life is a protracted struggle with poverty, a continuous make-shift, a perpetual racking of brain to make one rupee suffice for five, because they have been so unfairly handicapped at their start. And when, in this cruel conflict, they fail, how many are eager to assign a cause, manufactured out of fertile brains, why Dr. So-and-So has gone under water. "Poor fellow. He was his own enemy. He was above counsel and fretted under friendly advice. And he was besides this, a spendthrift, a man with limited means and unlimited notions," &c, &c. Or it may be, his friends (?) are both more frank and more graphic in their assignment of cause and effect. One shakes his head, another lifts his thumb to his lips, another coughs significantly, and *voilà tout*—Dr. A. and his misfortunes are summed up without a word of mouth explanation—summed up by fictionists who know nothing of his affairs, and whose most authentic information amounts to "they say." One of our ablest Indian contemporaries—Dr. WALLACE—through an admirable institution—Indian Medical Association—with which he has long been connected, has toiled zealously for years to enlist Government sympathy, or even to shame our rulers into modifying this state of affairs, but our consistent rulers, whose purses are untouched, smile complacently and exclaim "Bless my soul we can't interfere with fair competition." Quite true; but nobody wishes for that, so long as competition is fair. Is it so, in this case? We say emphatically—No. This is a question that must be

referred to first principles, and they imperiously insist that a State servant—as an indispensable and irreplaceable condition of his appointment—shall devote all his energies to State service. He cannot have any divided interests. At his time, all his ability, all his energy are for his 'sovereign' his *sovereign's* appointment, and this is a principle that governs all branches of our public service whether Government or non-Government. In no state is it permitted an officer drawing a regular salary—whether upon a graduation list or otherwise—to add to that salary one stiver by remunerative labour of any class or kind, in which he is personally engaged. Why should a doctor be exempted from this stringent rule? Why should an inflexible principle be invaded for his special behoof; why should Government stultify itself to put fees into his pocket? A Government engineer is not permitted to accept work from outside employers; a soldier, a priest, are all subject to this order, and to such an extent, that they may not even contribute to a journal as "own correspondent" without permission, under penalty of dismissal. Here, then, we find, when Government declares its inability to interfere, its excuse is baseless. Fair play, good conscience, nay, common decency, all demand a principle of consistency in Government which we regret is sadly wanting in some instances, and this is one. If for no other reason it should be just to all its subjects, because of its profession that it is a *Christian* administration.

SEROPATHIE OF DIPHTHERIA.

RECENTLY at a meeting of the Imperio-Royal Society of Physicians of Vienna, M. KASSOWITZ has announced the results of his researches upon the value of Seropathie in diphtheria.

In the first place he says, that in order to form an opinion upon the efficaciousness of this method of treatment, it is not sufficient to consider the statistics of different authors, what is necessary is to be assured that there has been a decrease in the *total mortality* from diphtheria.

If it turns out to be true that the mortality has decreased since the introduction of the serum treatment, it has still to be borne in mind that a notable decrease had already been observed before this treatment came into vogue.

On the other hand there are towns as St. Petersburg, Trieste etc, where the mortality from diphtheria has increased since serum was used. Another factor which has to be borne in mind is that the number of cases of diphtheria has very largely increased, for now, all affections of the throat benignant or not, are returned as diphtheria, provided LOEFFLER's bacillus is found. As a natural consequence the mortality *rate* has decreased to a considerable extent.

Finally the sick being more readily admitted to hospital, it is easy to understand that the recoveries are more numerous.

All these considerations show that we cannot compare present statistics with those of pre-seropathie days.

These statistics are still further discounted by the fact that most of them take no account of toxic diphtheria, or of complications. In fine they only afford information concerning the relative mortality from diphtheria, and not concerning the absolute mortality which is the only question of importance.

It is stated that the value of the serum has been demonstrated clinically, yet it must be remarked that two of the most serious complications, which are universally admitted to be caused by the diphtheria toxine, namely paralysis and renal troubles, are altogether unaffected by the action of the serum.

The number of cases of paratyphoid and diphtheritic nephritis has, instead of diminishing, increased, since the introduction of Seropneuma, all authors are agreed on this point.

This fact proves that the serum does not possess any antitoxic action; paralysis of the heart has also been observed in infants treated with serum.

Further it must be remarked that the action of the serum on the fever is disputed. While KOSSER considers it antipyretic, other authors deny that it has this action. It is the same concerning the favourable effect of the serum upon the general condition; it is affirmed by some, denied by others. Neither is there any settled opinion regarding the effect of the serum upon the local lesion, according to some it hinders the development of the false membrane and according to others it is powerless to prevent the invasion of the nasal fossae, larynx, etc.

Certain however it is that majority of fatal results are due to the spreading of the membrane to the lower respiratory passages.

On the other hand, from the point of view of the number and of the gravity of the tracheotomies for diphtheria, the situation has not been appreciably modified since the treatment by serum was adopted.

Finally, what goes a long way to detract from the confidence inspired in the value of the anti-diphtheritic serum, is the fact that the specific nature of LOEFFLER's bacillus grows very day more problematical, it is in fact found in sore-throat of the most varying character and even in many other non-diphtheritic affections.

SOME MEDICO-LEGAL ASPECTS OF THE CASE OF REGINA versus COLLINS.

This case in which Dr COLLINS was found guilty of manslaughter, by causing the death of Mrs UZIALLI through lacerating the uterus in the illegal effort to produce abortion, is of interest from many points of view, but particularly so as throwing light upon the unsatisfactory manner in which medical and other expert testimony is treated in the English law courts.

The fact that expert testimony has fallen into such general disrepute is entirely due to the system adopted in England.

The following questions and answers will serve to illustrate our meaning. The witness under examination was Sir JOHN WILLIAMS, the questions were put by Mr GILL. We quote from the *British Medical Journal*, July 9th, 1898.

"Witness continuing said he had examined DOUGLAS' pouch especially with regard to the adhesions DOUGLAS' pouch was practically obliterated in consequence of the sides being stuck together. There was some thickening.

Mr GILL "would you describe it as a deposit in the pouch?" Answer: It is a deposit, but thickening is the proper term for it.

Mr. GILL Was there a quantity of matter adhesions? Answer: No, there was no matter. There were three or four adhesions, the result of exudation of lymph.

Mr. GILL At present it is I who am cross-examining you. Were those old adhesions indicative of old peritonitis? Answer:—Yes and no.

From this we see that the examining barrister or counsel is able to put any question he pleases and in any manner he pleases, no matter how senseless or misleading it may be.

To the expert is allowed no latitude. No chance of explaining the misleading nature of the question, whatever the question put, he must answer it.

It is upon the issue of this interesting duel of wits that the Judge and Jury form their opinions, a Judge and jury who have presumably never heard of the existence of DOUGLAS'

pouch, and to whom the term "adhesions" and "exudation of lymph" etc., mean nothing.

In this case, as was forcibly shown, the whole of the evidence was of the most intensely technical description, and the experts whose testimony was called for, to throw the utmost light upon the difficulties, and to clear up the case in the interests of justice, were never for a moment allowed a free hand; they were hampered by all sorts of questions, many of these having for their object the confusion of the issues and the misleading of the minds of the jury.

Nothing is more remarkable in these cases than the ability with which the counsel for the defence makes up the most intricate technicalities and the way in which he turns every little point to the advantage of his client. To read Mr GILL's cross-examinations one would imagine that he had been practising elocutories for his entire career, yet most probably the whole of his information had been merely crammed up a few days previously. He had been no doubt carefully coached by some expert.

Had Sir JOHN WILLIAMS been allowed to ask him a few questions the extent of his knowledge would soon have been made clear.

This system opens out the widest possible door for the miscarriage of justice, and this has been made clear in more than one case, some of them historical.

They manage these things better in France, there, the whole of the medical evidence would have been submitted to a commission of medical experts. They would have sifted it to the bottom, and their conclusions would have been accepted without question or cross-examination in court. Who can doubt which is the better system?

THE EFFECT OF THE ANNOUNCEMENT OF PLAGUE ON CALCUTTA BUSINESS.

THE following remarks of Mr. DAVID YULE, Chairman of the Bank of Calcutta, Limited, made at the Bank's general meeting on the 30th July, deserve to be recorded in the History of the Calcutta Plague. They shew in strong relief the state of confusion into which the city was thrown by the sudden declaration of plague, without any previous warning, and bear out much that has already appeared in these columns.

"Although the Bank has made fair progress during the half-year I regret the general state of business in Calcutta has not been satisfactory and the depression caused by the severe stringency of the money market, was much aggravated by the unexpected announcement by the Government of Bengal that true cases of plague have been discovered in the town, and that certain measures would be enforced to prevent the spread of the disease. The loss which has accrued to the commercial community is enormous and incalculable, for in addition to the stoppage of the trade of the port for several days, the peace of the whole labouring population has been disturbed, and the good feeling between workmen and their European employers and overseers sorely tried. It is unfortunate that so important an announcement was made with apparently so little consideration of its possible effect on the trade of the province and on the minds and feelings of the people. The flight of nearly one-fourth of the inhabitants of the town and suburbs, during the panic which ensued, gave an opportunity to the ringleaders of disorder to show, how, by combination, the entire industry of Calcutta, including work at the Railway yards, the jetties and docks could be brought to a standstill. Workmen have been paid as much as four times their ordinary pay, in cases, where delay meant greater loss to the employer than this advance. The effect of this on others who have not received increased wages is clearly visible,

they are ignorant and stupid in their conduct and for the same reason, it is dangerous to assume that strict and stringent measures over vigilance, which is so essential to good and successful work. I do not speak from hearsay. I come into contact daily with several hundreds of Indian operatives, and have, therefore, the opportunity of noting the morose spirit and the lack of interest in their work, which the majority of them now display. The panic itself has happily subsided, and the people are now no longer afraid of the disease, which many of them believe to be a kind of fever attended by swellings, arising from weakness, which is not uncommon in Bengal during the monsoon months. In any case, plague is not the term to apply to an ailment which has not, except in less than a dozen cases, attacked two people in the same house; or confined itself to any particular part of the town. The word more fittingly describes the state of misery into which many thousands of our poorer citizens were thrown, by their eagerness to escape from the dreaded inoculator and the Municipal plague hospital. The mischief has been done and it is impossible to recall the past, but this black page in Calcutta's history teaches us that the Government cannot too fully take the people into their confidence before adopting any measure which interferes with caste regulations and the happiness and liberty of the subject."

PLAGUE IN CALCUTTA DISPUTED.

AT a recent meeting of the Municipal Commissioners of Calcutta, Dr. RAMMOY ROY, a most talented and experienced physician, a graduate of the Calcutta University, in supporting a resolution for a searching enquiry into the real nature of the disease prevalent in Calcutta and reported to be plague, "observed that there was a very general belief that the cases reported as plague cases, were not true cases of plague, and the Commissioners should try their utmost to remove the erroneous impression that they were true cases of plague from the minds of the people. The diagnosis of plague cases was a matter of great difficulty. The so called plague had been recognised as being in Calcutta and in Bengal ever since he commenced to practise as a medical man, that was to say, from the year 1871. He saw these cases when he was Resident Surgeon in the Mayo Hospital, House Physician in the Medical College Hospital, also when in officiating charge of the SUMBRHO NATH PAUNDIT Dispensary and in charge of the North Suburban Hospital in Cossipur, and also in some of the towns in Bengal when he was medical officer to Sir ASHLEY EDEN and Sir RIVERS THOMPSON's Government, and some cases in Dacca, Mymensingh and Pabna when on a river tour. Since May 1882 he had seen these cases year after year there was not a single year in which he did not treat at least 200 or 300 cases. From the day on which plague was declared in Bombay he kept a record of the cases which he had treated, and he found the number to be 362 in Bhowanipour and Calcutta and all of them had recovered, and he could even now give a reference to cases. There was a *pucca* case in the house of Prince MAHOMED BAKHTYAR SHAH, and 2 cases in the house of Babu MOHNEY MOHUN ROY about a year ago, and he could also give other cases regarding which the Commissioners could satisfy themselves. They had bubonic or glandular swellings in the groin accompanied with high fever rising up to 105° 8 with delirium and unconsciousness. But not one of those cases proved fatal. It required an experienced medical man to recognise and diagnose such cases. Those who had not much experience of diseases in Calcutta and Bengal, generally, were not able to recognise this form of disease. Medical men from Bombay, who had seen plague cases only, and nothing

but plague, would at such proceedings have been in an error, because they did not know the form of the case prevalent here. He doubted if even Dr. COOK, whose reputation in the profession was very high, had sufficient experience to differentiate between the disease which prevailed in Bengal and the true bubonic plague. Great experience was necessary to differentiate between the two forms of disease, and he could not too strongly impress upon the Commissioners the great necessity of having these cases correctly diagnosed and reported upon."

MEDICO-LEGAL ASPECTS OF THE BARRACKPORE MURDER CASE.

IN this case three soldiers of the Royal Artillery stationed at Barrackpore were charged with the murder of Dr. SIBGAR, a native doctor who practised in Barrackpore.

The medico-legal aspects of this case are of the greatest interest, and it was only when the medical evidence was called that the court began to show any sign of life.

It was shown that the cause of death was a severe fracture of the skull, which might have been caused by a kick with a heavy boot, or by a fall upon a sharp stone.

The case for the prosecution was that the fracture was caused by a kick given by one of those accused, and it was proved that there were no stones, such as could have caused it on the spot where the injury was received, the evidence as to the identification of the man who had given the kick was not sufficiently convincing and on this point the prosecution broke down.

This breakdown might not have occurred had the police done their work efficiently, and their negligence fully deserved the severe censure passed upon it by the Chief Justice.

It is a most remarkable thing that the boots, the very things which were alleged to have caused the fatal injury were almost overlooked. There was a sensation as of an electric shock throughout the court when a juror asked the telling question, if the injury was caused by a boot would not it bear traces of blood? This question was answered in a decided affirmative by Surgeon-Major KNOGH, A.M.S.

With respect to the boots there had been the most culpable oversight, the police had overlooked the probable importance of their dumb testimony they had been subjected to no scrutiny and in fact were only asked for and taken possession of some three or four days after the event. That they had been cleaned in the meantime, and all traces of the crime removed, if there had been any goes without saying.

Had these boots been taken at once and submitted to expert examination it is quite possible that the graver charge of culpable homicide would have been brought home to one of the accused.

In a case of this importance such neglect is most regrettable.

When Surgeon-Major KNOGH first saw the deceased he was unconscious, but seeing that perchloride of iron had been applied to the wound on the head, he inquired, and was informed that the deceased had himself given instruction for its application, from this it appears that unconsciousness was not instantaneous, yet no advantage was taken of this important interval to obtain any statement from Dr. SIBGAR, nor does he appear to have volunteered one.

This unfortunate as it is, is of less importance as it is not probable that anything he could have said would have helped towards identifying his assistant.

The failure to obtain a verdict of culpable homicide must be largely attributed to the faulty way in which the police work was carried out.

THE PLAGUE SOCIETY OF CALCUTTA

A meeting of the above society took place as we are told by *The Englishman*, on Tuesday evening, the 8th August 1905, at Patten's Entertainment Rooms in Calcutta. The meeting was not a public one, newspaper reporters, the other local dailies tell us, were excluded, but the representative of the *Englishman* was all there. Among those present were, the Inspector-General of Civil Hospitals, Bengal, the Principal of the Calcutta Medical College Hospital, the Superintendent of the Sealdah Medical School Hospital, the Superintendent of the Presidency General Hospital, all the Bombay Plague Doctors, the Health Officer, the Assistant Health Officer, the Chief Plague Officer, the Sanitary Commissioner of Bengal, the Protector of Emigrants, the Proprietor of the *Englishman* and the Surgeon-General's Head Clerk. No gathering could have been more representative of Calcutta official plague opinion, for besides the head, body and tail of the whole show, the official organ of the society was there.

There was a dinner and the usual flow of liquids, and after that the talking. They praised the Queen, the Royal Family and the Viceroy, and then they praised each other, and the buttering was very thick. One would have thought the "Blarney stone" was there in great proportions. They were all great men there. Not a single mediocre found a place in that exclusive assembly of seventeen barring the Head Clerk of course. One of the members presided and as a working member he spoke first. Then our worthy Health Officer—more power to his elbow—gave a neat little speech, and took the trouble to state that he had never kissed the "Blarney stone." JUSTICE upheld the Standard Bearer of Madras, and how he stood such a brisk fire of compliments, it is hard to say. Judging by the neatly turned speeches specially reported in the *Englishman*, and in the *Englishman* alone, both JUSTICE and BANNERMAN scratched each others backs in right earnest. But for loud-mouthed flattery commend us to CLEMORE. He charmed the tongue of HENDLEY into motion and it spoke as few tongues speak, except the *Englishman*. The head of the official plague show was a veritable phalanx in himself in support of the State diagnosis of Calcutta plague. Who will now dare to disbelieve? This conclave of the Self-adulation Society have patented an un-patented truth, stamped in all credibility by the overpowering conviviality of evening pleasures.

A discourse on plague and the gruesome details of necropsies did not seem to disturb the gustatory and digestive powers of the society, for all the horrors of plague dangers were strangely and charmingly obliterated by music and hilarious conversation. Altogether we do not find the smallest reason to congratulate the Plague Diagnosis Society on its nocturnal performances. The ostensible object of the meeting was to do honor to Dr. COOK, our robust Health Officer, who rightly deserves much credit for his indefatigable labours and his untiring zeal. But there can be no doubt that the evening was devoted to publicly ventilating and supporting the questionable diagnosis of the Risley Plague Commission, of the endemic glandular fever now prevalent in Calcutta, and styled by that commission, The Plague. What was more fitting than that a band of officials should stand by their masters. "The man who pays the piper has the right to call the tune," and in this particular instance, the gamut rang from top to bottom with plague—plague—plague. Still the tune falls flat, for THERE IS NO PLAGUE in Calcutta. Official opinion and official editors may keep on declaring this bubonic fever, plague, but non-official opinion is dead against this verdict.

RECOMMENDATIONS OF THE HEALTH DEPARTMENT

THE Health Officer of Calcutta, Dr. F. R. COOK, D.M.S., in his Note on the "Health Department Budget Estimates" makes the following suggestion: "I would suggest for the consideration of the Commissioners that instead of appointing one of our present uneducated Sanitary Inspectors, they should make it an acting appointment only, and advertise in the English papers for a Certificated Sanitary Inspector who has been through the course at the Sanitary Institute, and passed his examination, besides having practical experience in the work of a large town. I believe the services of such a man could be obtained for about Rs. 400 a month and horse-allowance, and that he would prove more valuable for the class of work that has to be done than those of the B. E. Officers, and other gentlemen of high social and professional attainments. I do not consider that any one of the present staff of Sanitary Inspectors is properly qualified for the post in sanitary knowledge, or has the personal qualifications which are necessary for the efficient control of a large establishment."

From this it would appear that there is no place in India where men are trained in sanitary work. This is not to be wondered at considering how much our whole educational system has fallen behind the times, and the snail's pace at which things move in India.

We present the fact to the authorities as another direction in which Reform is urgently needed. Will Surgeon-Major General HARVEY, O.B., kindly make a note of this.

We show in our Editorial columns how the government in its own admission has grievously failed in its efforts to educate medical men and nurses, but surely it should not be beyond its power to turn out capable sanitary inspectors. There is plenty of material, and examples of how things should not be done, to provide valuable instruction for the responsible authorities.

THE ROYAL ARMY MEDICAL CORPS.

The following is the text of the Royal Warrant authorising the formation of a Royal Army Medical Corps:—

ROYAL WARRANT.

Formation of the Royal Army Medical Corps.

Victoria R.I. Whereas We have deemed it expedient to alter in certain respects the conditions under which officers employed upon the medical duties of Our Army are at present serving;

Our Will and Pleasure is that the officers below the rank of surgeon-major-general serving in our Army Medical Staff shall be formed into a corps together with the warrant officers, non-commissioned officers, and men of Our Medical Staff Corps;

It is Our further Will and Pleasure that the designation "Medical Staff Corps" shall be abolished and that the Corps formed as above mentioned shall be styled the "Royal Army Medical Corps."

The following alterations will consequently be made in the ranks of the medical officers of Our Army:—

Present Ranks.	New Ranks.
Surgeon-Colonel	Colonel.
Brigade-Surgeon-Lieutenant-Colonel	Lieutenant-Colonel.
Surgeon-Lieutenant-Colonel	Major.
Surgeon-Major	Captain.
Surgeon-Captain	Lieutenant.
Surgeon-Lieutenant	

The medical staff of Our Army shall in future consist of Surgeon-General (ranking as Major-General) and the title of Surgeon-Major-Generals now serving shall be altered accordingly.

Officers of Our Royal Army Medical Corps holding appointments in Our Household Troops shall be borne as second

officers on the establishment of Our Royal Army Medical Corps and shall be dealt with as regards pay and promotion in accordance with the rules laid down in Articles 284, 285, and 287 of Our Warrant for the pay, appointment, promotion, and non-effective pay of Our Army, dated 26th April, 1897.

Given at Our Court at Windsor this 26th day of June, 1898, in the 63rd year of our Reign.

By Her Majesty's command, LANSDOWNE,
Army Order 25 of 1898.

MR. BALFOUR ON MEDICAL RESEARCH.

On July 19th the First Lord of the Treasury distributed the prizes to the successful students at Guy's Hospital. After the prize-giving he addressed his audience in a telling speech. Commencing by paying a warm tribute of esteem to the nobility of the medical profession, and having referred to his recent election as a governor of the hospital, Mr. BALFOUR proceeded to point out how science was necessarily getting more and more specialised and that therefore medical men and those whom they would have to treat were being gradually compelled more and more to rely upon those whose work was mainly research. He continued:—

"The man who would succeed in research, the man who, at all events, desires to devote himself to research, must not be asked to burden himself with other labours. He has upon his shoulders not merely what I may call the specialised work of his profession, but he must have a sympathetic and appreciative eye to everything which is going on in other departments of science, so that even where he cannot follow those other departments minutely he knows by the instinct of genius where to pick up those new discoveries which may help his own special branch of research. For men of that kind I think we require further endowment. I have all my life been an ardent believer in the cause which is often laughed at—the cause of the endowment of research. In that cause I most firmly believe, and I think there is no branch of knowledge in which it may find a more useful field of application than in that of advancing medical knowledge."

We are glad to find such opinions held by a man of Mr. BALFOUR's position and attainments, but in the British Empire it would appear that the scoffers to whom he alludes are in the majority.

His remarks furnish a clue to the absence of research in India, the Government is too intent upon getting its pound of flesh out of every medical man it employs to have time or money to throw away in this direction.

PROFESSOR KOCH ON PLAGUE.

In honour of Professor ROBERT KOCH, the German Society for Public Hygiene held a special meeting on 7th July, in the hall of the Zoological Gardens, on which occasion KOCH delivered an interesting address on bubonic plague and its dissemination. KOCH calls the plague primarily and essentially a rat's disease; from rats the infection is carried to man. As the chief foci of the disease—places where it never entirely dies out, and whence it spreads at intervals—he named Mesopotamia, to which country all the epidemics that in olden times were the scourge of Europe can be traced; Thibet, whence the infection is carried to China and India; Western Arabia, South of Mecca, where a residuum has been left; and British Uganda in Central Africa, a hitherto unknown focus, from which, however, epidemics have sprung, and can be traced as far as the North Coast of Africa and the Nile Lowlands. At Kisiba, a German settlement on the West Coast of the Victoria Nyansa, Professor KOCH and Dr. ZUPITZA, had occasion to observe cases of a disease with exactly the same symptoms as Chinese and Indian Plague. The disease the natives call "lawunga;" it has an enormous mortality (about

80 per cent.), and is extremely infectious. Clinical observations were, of course, registered, the blood and the glands histologically examined, and five necropsies made. Spontaneous cases of rat disease were likewise observed, and experiments on animals by feeding and inoculation carried on successfully. KOCH found that here, too, the human epidemic is preceded by a rat epidemic. Natives, as soon as they see rats lying dead, fly from their huts. The Kisiba banana plantations abound in rats, thus forming a most favourable locality for the development of plague. Still, the Kisiba plague is only an offshoot from Uganda, brought there eight years ago by a single case. In Uganda itself—so the missionaries declare—plague has been endemic from time immemorial. KOCH thinks it very possible that the projected railway from Uganda to Mombassa may bring the plague to the coast, and cause an epidemic there, but he hopes that modern science—in conjunction with the cleanliness of advancing civilisation—will before long be successful in stamping out the disease.

THE ANGLO-INDIAN CAUSE. UNION AND DEFENCE.

We are so deeply and fervently interested in the Cause of the Domiciled British Community of India, a CAUSE that most intimately concerns not only the well-being of every European and his descendants who have made this country their home, but the well-being of the country itself and all sections of its indigenous population. The grievance of the Domiciled Britisher is that he does not get FAIR PLAY in the game of life in India. The Indian Government knows this grievance only too well, but neither the interested gang of free-booters at Simla nor their co-conspirators at the India Office in London, will disgorge one penny's worth of their ill-gotten booty till they are compelled to do so. UNION AND DEFENCE are words that are synonymous with VICTORY and they are the two words which form the key-note to constitutional agitation against the Indian Government. We suffer from serious wrongs in India. There is only one way to get these wrongs righted. Let England and England's people know our wrongs, let them thoroughly understand them, and the citadel of prejudice and iniquity at Simla and Westminster will fall into instant decay. A combined and determined union of the Anglo-Indian race would quickly bring the effeminate officials of Simla to their right senses. Let no Anglo-Indian cease to agitate for the cause of FAIR PLAY, till all the shackles of Indian serfdom have been broken, and a FAIR FIELD opened to the competition of the imported Britisher, the domiciled Britisher and the Indian alike. We invite special attention to the papers on the Anglo-Indian Cause to be found in this number and we entreat every Anglo-Indian who reads them to act upon the advice therein given. Let every British reader join the IMPERIAL ANGLO-INDIAN ASSOCIATION AT ONCE.

STANDARD OF MORALITY ACCORDING TO THE "MEDICAL BRIEF."

No individual or nation has the right to set up a standard of morality for another, farther than to "Do unto others as they would have others do unto them." We are too apt to mistake a desire to impose our own wishes and views upon others for the self-sacrificial zeal of the true reformer. Morality is too often mere narrow-mindedness, bigotry, intolerance, which easily degenerate into persecution. Love of dominion and lust of power, obnoxious with the better than-thou sentiment, actuate the moralist far oftener than he suspects.

For instance, men of delicate appetites look with scorn upon the grossness of other men whose vigorous and healthy

common claim for indulgence. Nature, the poetess condemns the sybarite, he should reflect upon his own poverty of body and ask himself if he would feel the same intolerance had he the other man's superior physical endowment. The man who stokes when he smokes a cigar is apt to think that smoking is wrong, but he has no right to prohibit others from the exercise of a free will choice. If a man finds that certain articles of food disagree with him, he must not try to prevent others from eating them.

We learn by our mistakes. The fullest of liberty choice is essential to progress. No man, or nation of men, is perfect, and to generalize for the race from a narrow experience is hurtful. To lay down arbitrary standards is not only injudicious, but it does no good. It has no permanent effect and is demoralizing. People will always find a way to evade the spirit of laws which hamper Nature. When an individual, or a nation, reaches the moral state through evolution, they will keep the moral law, not from fear, but from love. Compulsion, therefore, is not the weapon of the true reformer. He instructs, advises, suggests, exemplifies in his own person the great truths which he believes. Those who really desire the welfare of men are satisfied to teach and not to coerce.

THE ACCIDENT TO THE PRINCE OF WALES.

We are sure that the members of the Medical profession share in the universal expression of sympathy with the Prince of Wales on the accident which has befallen him.

The Prince was seen immediately after the accident by Sir FRANCIS LAXING who summoned Sir WILLIAM MACCORMAC and subsequent consultations were held with Sir THOMAS SMITH and Lord LISTER.—The following statement has been sanctioned for the benefit of those who desire authentic information:—

"On Monday morning 18th July, while coming down the spiral staircase at Waldegrave Manor, he missed his footing, and in the sudden severe effort made to save himself from falling, sustained a fracture of the left patella.

On examination it was found that the line of fracture was nearly transverse and close to the upper margin of the patella. About one-fifth of the bone, somewhat crescentic in shape, was torn away, along with the tendinous insertion of the quadriceps extensor, and the gap between the fragments amounted to a little more than 2 inches. The Joint was distended with blood. Means were adopted to immobilize the limb, bring down the upper fragment, and to prevent tilting. This has proved so far successful, that upon examination to-day it was found that the interval between the fragments was greatly diminished, not being now more than a quarter of an inch, and the effusion in the joint is lessened considerably. The condition of the illustrious patient is in other respects most satisfactory, and he is bearing the enforced restraint with exemplary patience and good temper."

We have since heard that the effects of the injury will be permanent, a slight shortening of the injured limb being unavoidable.

AUTO-INTOXICATION.

THIS is an almost unknown subject which supported by (1) analogy, and evidence drawn from (2) clinical pathology and (3) clinical therapeutics, is within limits a useful working hypothesis for explaining a great many states where pathology is obscure, but to form a hypothesis is one thing, to verify it quite another and so far beyond predisposing testimony there is next to no direct evidence of "a body whose function prevents a certain form of degeneration, which in its absence the body tends to take on." We also with the theory of health depending upon efficient assimilation and

excretion while failure to eliminate and cast out waste products or errors in those processes required for conversion of binary or ternary into quaternary and higher combinations lead to diseases. Thus chemists prove (1) the poisonous character of the albumoses and peptones formed during normal digestion and (2) the presence of toxic alkaloidal bodies in living and in dead tissues, as well as (3) that certain animal extracts can coagulate the blood. SIDNEY MARTIN shows that the (4) poison of diphtheria is a product of our own body under the stimulus of a peculiar bacillus and BROWN SQUARD claimed (5) an *etiam prout* for the glandular structures of the body while BOUCHARD declares, which BECK disputes (6) the toxicity of urins in the sole of dynamic causation, which is attributed by some of others to (7) defective excretion of waste products. But none of the poisons found during digestion have ever been found in the blood, and in urine the amount of such bodies is so minute as to throw doubt on their existence, while it is equally doubtful whether animal extracts play any part in morbid processes.

THE HEROISM OF A MEDICAL OFFICER.

THE *British Medical Journal* says:—"Sir WALTER FOSTER has submitted the following interesting statement for the consideration of the Secretary of State for India, in reference to the campaign on the Indian Frontier: "Lieutenant FORD, of the Malakand Field Force, was dangerously wounded in the shoulder, and was bleeding to death from the bullet having cut the main artery, when Surgeon-Lieutenant HUGO came to his aid. The fire was too hot to permit lights to be used to examine the wound, and there was no cover: nevertheless, the surgeon struck a match, and examined the wound. The match went out amid a splutter of bullets which kicked up the dust all round, but by its uncertain light he saw the nature of the injury, and seized the bleeding artery, and as no ligature was available, he remained for three hours under fire holding the vessel between his finger and thumb. When, at length, it seemed that the enemy had broken into camp, he picked up the officer, who was unconscious from loss of blood, and bore him into a place of safety without relaxing his hold of the artery." Sir WALTER FOSTER, has pressed on the authorities the expediency of rewarding in a suitable manner this splendid act of devotion.

THE SALE OF ABORTIFACIENTS AND CRIMINAL ABORTION.

A CORRESPONDENT writes to the *British Medical Journal* as follows:—

I beg you will give me space to point to the class of advertisements which flood the columns of many weekly and some daily papers addressed to "ladies requiring assistance." No doubt the greater number of these are fraudulent and do not fulfil their promise, but they work untold mischief by offering inducements to young and thoughtless women to yield to temptation under the strongest assurance that whatever may happen all will be "put right." So audacious are these announcements, and so long have they gone on with impunity in otherwise respectable papers, that it is no wonder a certain class of persons have been educated to look upon abortion as hardly constituting an offence. Fashionable women whose maternal instincts have been blunted or lost amidst the whirl and excitement of social engagements, fly to purveyors of these nostrums to rid themselves of the irksome encumbrance of children, and, getting no relief, sometimes tempt their medical attendants to risk their reputations in according to their wishes, happily with very rare success. Nevertheless, it must be confessed that there are men in my profession whose morality in these matters allows them, while ostensibly employing means for the treatment of other conditions, to endeavour to bring about the results indicated. I think this grave statement with the greatest diffidence. It is a state of things which a medical journal has described as "an abominable traffic in the suppression of which all decent citizens are interested."

DEATH OF AN OLD INDIAN DOCTOR.

SURGEON-GENERAL FREDERICK MORRISON CLIFFORD died in London on 16th June. He entered the Indian Medical Service (Bengal) as Assistant Surgeon on 4th April 1813, and was placed in medical charge of the European Depot at Chinsurah. In the following year he was attached to the 10th Bengal Cavalry, with which regiment he remained until 1854. In 1856, on return from furlough, he was appointed to the charge of the 6th Native Infantry, and on the mutiny of that regiment was successively in medical charge during 1857-58 at Allahabad of the Depot Hospital connected with General HAVELLOCK's brigade and of the general depot hospital. In June, 1857, he was promoted Surgeon, and in the following year was attached to the Field Hospital, Fategarh. While attached to the 10th Bengal Cavalry, then known as the Cavalry Regiment of the Bengal and Madras Legion, throughout the campaign against the hill tribes in Sindh under Sir CHARLES MAPIER, he also served for a short time with the Cawnpore levy in co-operation with Lord OLYDEN's final campaign in Oude in 1868. He was promoted Surgeon-Major in 1863, retired in March 1871, and was promoted Deputy-Surgeon-General in April 1874. He was a man of amiable and upright disposition, and discharged the varied duties which fell to his lot with zeal and efficiency.

PLAGUE IN BOMBAY.

THE plague in Bombay is not dying out by any means as fast as many would wish, having shown a tendency to diminish, it is now in the most disappointing manner again showing a tendency to increase.

The following table shows the decline and rise in plague during the last nine weeks.—

Week ending 24th May	101
" 31st "	84
" 7th June	44
" 14th "	26
" 21st "	15
" 28th "	53
" 5th July	38
" 12th "	53
" 19th "	68

In comparison with this Calcutta may well congratulate herself.

It is too early as yet to pronounce any opinion on the Bombay increase, or to forecast the chances of a fresh recrudescence, still the figures are not encouraging and they will be anxiously watched.

TREATMENT OF PELVIC SUPPURATION BY INCISION OF THE POSTERIOR OUL-DE-SAC.

M. M. QUENU and RICARD consider that this procedure is a matter of urgency where there is a collection of pus due to acute peri-uterine suppuration.

When the collection presents in the vagina, the former incises the most prominent point, when it does not present in the vagina he incises the cervical mucous membrane, and separates it along the posterior aspect of the uterus until the collection is reached.

On the other hand when the pelvic suppuration is chronic, though the vaginal incision may be indicated, he does not regard it as the best treatment, it is only a temporary measure, the first step towards radical intervention.

Mr. RICARD thinks that this incision in chronic pelvic suppuration can only bring about a temporary improvement.

For complete cure other measures will be necessary, either a laparotomy or a vaginal hysterectomy according to circumstances.

THE FAMOUS DECLARATION OF AMERICAN INDEPENDENCE.

ALL right thinking men and women will read the following lines with pleasure and with pride. They form the text of the Declaration of American Independence, made and signed and sealed on the 4th day of July, 1776. We quote from J. O. BIDPATH's History of the United States of America, page 310, a book which every member of the domiciled British Community of India should read, mark, learn and inwardly digest:—

"The leading principles of the Declaration of Independence are these: That all men are created equal; that all have a natural right to liberty and the pursuit of happiness, that human governments are instituted for the sole purpose of securing the welfare of the people; that the people have a natural right to alter their government whenever it becomes destructive of liberty; that the government of GEORGE III had become destructive of liberty; that the despotism of the King and his Ministers could be shown by a long list of indisputable proofs—and the proofs are given; that time and again the colonies had humbly petitioned for a redress of grievances; that all their petitions had been spurned with derision and contempt, that the king's irrational tyranny over his American subjects was no longer endurable; that an appeal to the sword is preferable to slavery; and that therefore, the United Colonies of America are, and of right ought to be, free and Independent States. To the support of this sublime declaration of principles, the members of the continental congress mutually pledged their lives, their fortunes and their sacred honor."

THE EDUCATION OF DEAF-MUTES IN INDIA.

SAYS the *British Medical Journal*:—There exist in the Indian Empire, according to the most recent census, some 150,000 deaf-mutes. No provision has hitherto been made for the special education of the class with the exception of a school in Bombay, containing about thirty pupils, and some private efforts of a limited description. A petition has recently been submitted to the Secretary of State for India by some educated deaf-mutes of Bombay, pointing out the absence of organised and adequate arrangements such as exist in all civilised countries for the purpose of enabling persons afflicted with the loss of the sense of hearing and speech to overcome, in so far as that is possible, the serious disability thereby entailed, so as to fit them to participate in the enjoyment and utilisation of life. The petition has been referred for the consideration of the Government of India, and it is certain that the charitable impulses of Indian administrations which have inspired such magnificent undertakings for the relief and restoration of those disabled by sickness, will result in the establishment of schools in all the principal centres of population for the special education of the deaf-mute.

A PHYSICIAN'S INFLUENCE.

SAYS the *Medical and Surgical Reporter*.—It has occurred to us many times in the past that physicians do not pay enough attention to the influence on their business, of the conduct of themselves and their families. With this in view we wish to call the attention of our readers to this point. In our estimation a physician practicing outside of the larger cities must be a married man in order to be a success, and must have for his life partner a woman who is discreet, for even though he tries to keep separate his professional and home life, many things are repeated as coming from the doctor's wife, "and, of course, she knows," which become so distorted in the rounds of gossip that the patient's family on hearing them will "never want that doctor again."

MEDICAL SLANDERS.

THE case we referred to in our 1st August number, is thus commented on in the society paper of Calcutta—the *Indian Planter's Gazette* of the 30th July :—

"We are apparently on the fringe of a little breeze amongst the members of the medical profession in Calcutta, for the story as it is told us runs thus :—Foul slanders have recently been going the rounds of Calcutta society about a certain successful physician who is not in the service of Government. This gentleman tried in vain for some months to track the originator of these harmful attacks upon his character. Rumour pointed to a co-specialist, but this tactful reviler vented his poisonous darts in a manner that precluded direct evidence against him. A few days ago, however, a certain Surgeon-Major of the Indian Medical Service, who holds a sort of roving commission to do anything or nothing, whispered these spiteful and cruel insinuations to a friend and patient of this other doctor's, at a certain club in a hill station. The friend conveyed the hurtful story to his doctor, and the doctor instantly got his solicitors to demand a retraction and apology from the Surgeon-Major and threatened a legal prosecution otherwise. The Surgeon-Major, knowing there was only one witness against him, thought it best to deny having made the defamatory statements, and thus escape the rigors of the law. It is hoped, however, that this gallant representative of some branch or other of medical science, will now learn to be careful not to accuse his brother professionals in other branches of medical science, in the exercise of whose peculiar calling, there is the ever present likelihood of misrepresentation, which can be most satisfactorily cleared up when sterner facts are gone into."

We learn that these official slanderers are a "trinity" of mischief. One is the Surgeon-Major above referred to, who was threatened with prosecution, the second is a certain Brigade-Surgeon who is assisted in his back-biting and other mischievous and offensive propensities, by a junior member of the Indian Medical Service, who follows him like a shadow of evil. This trinity of scandal mongers are hereby warned to be careful of their cowardly and spiteful doings, for not only might they quite unexpectedly be caught tripping in this rather familiar game of stabbing their professional competitors in the dark, but the glass houses in which they themselves live, might, if the panes be broken, allow daylight to enter upon some uncanny truths and some still uglier skeletons.

REMARKABLE LIGHTNING ACCIDENT AT MADHUPUR.

On Tuesday, the 9th of August, about 11-40 A.M., at Madhupur station, on the E. I. Railway, 188 miles from Howrah, Miss LILLY SOLA, a young lady eighteen years of age, living with her sister, Mrs O'BRIEN, was struck by lightning, death being instantaneous. Her sister at the time was sewing in the next room; she, of course, heard the thunder, but never for a moment thought her house had been struck by lightning. Smelling something burning, she went into the next room, when to her surprise and consternation, she found the room full of smoke and flame, Miss SOLA was in flames, on a chair, bending on her left side and about to fall to the ground; she rushed to her aid, supporting her with one hand endeavouring to tear her clothes off, and extinguish the flames at the same time. The lightning all the while flashed about the room, fortunately without touching Mrs O'BRIEN in any way. Strange to say, a lifeline passing by the deceased, which happened to come into the room at the time, was scorched about the hind legs.

There were about seven distinct crashes of thunder, and it is believed the place was struck about the fourth crash.

The thunder-bolt at first struck a piece of iron attached to the top of a lathe in the opposite compound, used for drawing water out of a well. It passed off, then came through the chimney of the house, ran along the iron girder in the roof, down the chandelier, smashing it and the furniture about the room to atoms. Deceased had just sat down at a table under the chandelier to write. The fluid caught the hairpins in her head melting some and twisting others, ran down the right leg, shattering her boot and clothes in shreds. It ran along the ground, and forced its way out in three different places.

The body was placed in an air-tight coffin and taken by the early morning train on the 10th instant to Asansole, to be entered in the family vault, with Roman Catholic rites.

ABUSES IN THE I. M. S.

The *Lancet* says :—"The system of appointments in the Indian Medical and Civil Services is open to much abuse. One constantly hears that so-and-so has been very fortunate in obtaining some particular berth. It is well known, however, that the so-called "luck" depends upon patronage. With the Civil Service the medical profession has of course little concern, but in both services the evil must be equally detrimental. If it does nothing else it stifles independence of character and original work. It would perhaps be equally unsatisfactory to grade the various appointments and to fill them by a process of pure seniority. The essence of the evil as it exists now probably lies in the power of patronage given to certain officials. A possible solution of the difficulty in properly filling up these posts might be found by the appointment of an independent board. Such a board with definite instructions to appoint on certain definite lines, might certainly remove some of the anomalies and grievances which now exist. The Government services naturally attract a large proportion of the ablest men, and the appointments under Government should be far removed from the semblance of favouritism. The best work will never be put out until this principle is recognised and acted upon."

DEATH OF SURGEON GENERAL MORICE, I.M.S.

SURGEON-MAJOR-GENERAL JOHN CHARLES MORICE, I.M.S., who died recently in London, entered the Indian Medical Service in 1856, at the age of 21. He served in the Indian Mutiny, and was present at the relief of Lucknow, and at the siege and capture of that town, also at the engagements at Cawnpore, Seraihat, and Kulee Nadlee, and at the capture of Fategarh and Bareilly. He was also employed in the Hazara campaign of 1868, and was present at the operations on the Black Mountain, for which he received the medal and clasp. In 1885 he served in the Sudan campaign, was mentioned in despatches, and again received the war medal and clasp. The breakdown of his health, which compelled his retirement, alone prevented him from reaching the highest posts in India. He was a man of genial and happy disposition, and his loss is deeply lamented by his many friends.

A WELL-DESERVED ENCOMIUM ON DR. RAYE.

SIR MACKWORTH YOUNG concludes his review of the Punjab Dispensary Report for 1897 with the following eulogium :—"The thanks of the Lieutenant-Governor are due to Surgeon-Colonel RAYE for his report and for his administration of the Department throughout the year under review. Dr. RAYE is about to proceed on furlough, and it being understood that he will not return to duty, the Lieutenant-Governor desires, in conclusion, to convey to him his warmest acknowledgements of the professional skill and knowledge which have thrown light on many difficult and obscure questions during his tenure of the office of Inspector-General of Civil Hospitals, of his sympathetic co-operation with Government, and the cordial relations which he has maintained in his Department."

NEW MEMBERS OF THE INDIAN MEDICAL ASSOCIATION.

The following have joined the Association since our last publication —

F. A. Campbell, Assistant Surgeon, Stratford House, Nagpur.
Ferdinand F. Harvey, Assistant Surgeon, D. 14 British Field Hospital, Malakand Force, Camp Kehar.

George Meyer Rappa, Apothecary, Alar Gajah, Malacca.
K. Narain Chuckerbatty, Jokai Tea Co., Tippiak Tea Estate, Dibrugarh, Assam.

Laxman Kishoo, C.M.S., Harda District, Hoshengabad.

P. T. Velu, C.M.S., 68rd B. M. J.

C. Mangaya Nayda, C.M.S., Civil Station, Chicacole, Ganyam District.

Jwala Pershad, C.M.S., Karimganj, Fatehgarh.

Kiripale Raman Nambayar, L.M.S., Ponnai, Malabar.

G. Nalin Khan, C.M.S., Jail and Police Hospitals, Secunderabad.

Ghulam Ali, L.M.S., Military Hospital, Patiala.

THE COLLINS CASE.

SAYS THE LANCET:—"A contemporary publishes a letter on the Collins case, in which the following question appears: 'Why is the West-end of London, full of private hospitals and nursing homes established mainly for these practices?' We have never heard of such a hospital or home, nor do we believe that one exists. We may point out that did such a place exist, nothing would be easier than the detection and conviction of the persons conducting it, for the first discontented nurse or servant could supply to the police evidence sufficient for the purpose. A place used 'mainly' for the reception of abortion cases could readily be distinguished from the reputable home hospitals which have occasionally to admit cases of abortion from natural causes or its sequels."

THE GENERAL MEDICAL COUNCIL AND IRREGULAR PRACTICE.

DR. FARQUHARSON asked the Chancellor of the Exchequer whether, having regard to the fact that a sum of £5000 a year of public money was paid to the council of the Incorporated Law Society to assist them in purifying the legal profession, he could see his way to make a similar grant to the General Medical Council to enable them to undertake the prosecution of irregular medical practitioners.—Sir MICHAEL HICKES-BRACH replied that the sum of £3500—not £5000—was voted to the Incorporated Law Society for this purpose. It was a very small fraction of the yield from the special duty on solicitors' certificates which went to the Exchequer. No such tax was imposed upon medical practitioners and therefore no question of a similar grant arose.

NEW MEMBERS OF THE INDIAN MEDICAL ASSOCIATION PROVIDENT FUND.

The following have joined the I.M.A. Provident Fund as associate members since our last issue:—

Dr. Kirty Narain Chuckerbatty, Tippiak Tea Estate, P.O. Dibrugarh.

K. Krishnaswamy, C.M.S., Yamdur, Jahgir Dispensary.

Yaluri Ammatyga, C.M.S., Govt. Lunatic Asylum, Waltair, Visagapatam.

Robert James Owen, Assistant Surgeon, Medical Officer, I. M. Ry, Bina.

George Meyer Rappa, L.M.S., Alar Gajah, Malacca, Straits Settlements.

Abmad Baksh, C.M.S., No. 1 Mahat Mountain Battery, Fort Lockhart.

K. Raman Nambayar, L.M.S., Civil Apothecary, Ponnai.

F. A. Campbell, Assistant Surgeon, Stratford House, Nagpur.

ANOMALISTIC MEDICAL PENSIONS.

In the Military Works and other Departments in India Warrant Officers and Honorary Commissioned Officers obtain Pension of their rank on their retirement, if only enjoying such rank for twenty-four hours, with the Indian Medical Subordinate Department, it is not so, luckless members of which service must serve three years in any rank are its established Pension is admissible, thus a man with near forty years' service of the one department can and does obtain less pension than one of thirty years in another. Is this department so utterly in the shade that no remedy is considered necessary for such an anomaly. Where are the heads of the Medical Services in India? In leading strings.

PROGNOSTIC BY PROXY.

It is related of a noted English Bishop who had for years nursed the fear that he would some day become paralysed, that on one occasion at a dinner, he suddenly interrupted the guests at the table by exclaiming that his worst fears had been realised at last; that he was paralysed in his right lower limb, that he had been pinching his thighs for some moments, and was unable to detect the slightest feeling. A lady sitting next to him assured him that he was mistaken, for it was her limb he had been pinching instead of his, the silk of the lady's dress being difficult to detect from the silk of the Bishop's robe.

AN ERNEST HART SCHOLARSHIP.

The Council of the British Medical Association resolved at its last meeting to found as a memorial of the late Mr. ERNEST HART a scholarship to be called "The Ernest Hart Memorial Scholarship for Preventive Medicine." It was felt that no more fitting means could be found to commemorate at once Mr. HART's great services to the British Medical Association and to the advancement of the study of preventive medicine. The scholarship, which will be of the annual value of £200, will be tenable for two years.

HEAD CLERK TO THE I. G. OF CIVIL HOSPITALS, BENGAL.

It is stated that the present head clerk, or as he is now styled, the Personal Assistant to the Inspector-General of Civil Hospitals, who resides with the Sanitary Commissioner of Bengal, possesses no form of medical or sanitary qualification, and that he has not had a single day's medical education. Yet the preparation of statistical health reports are, it is stated, entrusted to this assistant. We believe that if this statement is correct an immediate change ought to be made in the *personelle* of this office.

SHORT ITEMS.

Brigade Surgeon O. H. Joubert, professor of midwifery and general practitioner in Calcutta, has hurried home to England. It is rumoured that he is to take an active part in the Commission now said to be sitting, to discover the bacillus of ectopic gestation, as also to assist in the deliberations of the Committee now said to be carrying on its labours in the Channel Islands, for the purpose of testing the weight carrying power of military captive balloons.

SAYS THE *Medical and Surgical Reporter*:—"Silence is probably the safest rule for the physician to follow in relation to secrets which come to him in his professional capacity. It may sometimes seem his duty to warn those interested, but he must be very sure of his ground before doing so. A notable instance of the dangers incident to the utilization of knowledge gained under the seal of professional secrecy was furnished in the now celebrated case of *Kington vs. Playfair*.

On Friday the 6th August the House of Lords passed the Government Bill for improving the methods of vaccination.

but rejected an amendment which had been accepted by the Government and the House of Commons whereby the compulsory clause was waived, if conscientious objection was declared before a Magistrate. The House of Commons have maintained the amendment, but the Lords will probably not insist upon its rejection.

At the Bristol Amusees which were held recently, the Lord Chief Justice of England in alluding to the medical profession remarked, that he thought there was no profession in the world which rendered more entirely gratuitous services than the members of the medical profession, and added that so far as his experience went there were not the sordid considerations in this profession, which were present in others.

In Japan not only is vaccination compulsory, but the law directs that revaccination shall be practised after every five years. In 1896, legal enactments were especially made for the introduction and distribution of vaccine, and calf lymph is exclusively employed, prepared with antiseptic precautions. Thus the Far East profits by the teaching of the West, and afterwards the West has to learn wisdom from the East.

The history of the so called Plague in Calcutta is, it is rumoured, to be written by an officer of the Royal Engineers, the precedent being that the Plague Report of the Government of India was written by a civilian (Mr. Nathan. '18) We vote that the Report be entrusted to the Inspector-General of Civil Hospitals, Bengal, who has little or no work to do, or to his assistant, the Sanitary Commissioner of Bengal, who has still less to employ his time.

Mr. Lloyd, an ex-Military Assistant Surgeon, who holds the post of Superintendent of the Manicktolla Plague Hospital, was the subject of an enquiry as to his professional fitness for the position he holds. The General Committee of the Calcutta Municipality upheld Mr. Lloyd's appointment and recommended his fitness for the same.

The number of officers to be admitted to the Indian Medical Service, at the examination held this month in London will probably be raised to twenty-seven, to supply the deficiencies caused by the late unusual demands for Medical Officers, and the abnormal invaliding due to restrictions placed upon ordinary leave.

There is nothing which cheers up your spirits like a dose of Epsom salts. They have gone out of vogue, but a tacit compliment is, notwithstanding, constantly being paid to them, for people still find the efficacy of the more expensive bottled waters which contain the salt.

Surgeon-General A. A. Gore, P. M. O. Her Majesty's Forces in India, will, in all probability, be succeeded in December next, by Surgeon-General W. Taylor, M.D., at present employed on the staff of Major-General W. F. Gatacre C.B.

"My husband has all the virtues but one," remarked the wife of a struggling young doctor. "What is that?" asked her sympathetic friend. "Patience," replied the young wife.

Surgeon-Major Herbert Jeyki Dyson who occupies the post of Sanitary Commissioner of Bengal, is L.S.A. Lond. 1893, M.R.C.S., Eng. 1893, and F.R.C.S., 1904. He holds no Diploma in Public Health or in Sanitary Science.

Surgeon-Lieutenant Colonel J. H. Fitzpatrick has been permitted to retire from the service and will be succeeded at

Colchester, where he has been stationed for so many years by Surgeon-Captain D. Simpson.

At a meeting of the University court held on 18th July, Charles Hunter Stewart, M.B., D.Sc., M.D., was elected to the Bruce and John Usher chair of Public Health in the University of Edinburgh.

The Horse Guards Army Order authorising the formation of a Royal Army Medical Corps, has been received here, and is applicable to officers serving in India, who from to-day use new ranks therein sanctioned.

Dr. Duval, Surgeon-Major of the 126th Regiment of the French Infantry, has been authorised to follow the British expedition on the march to Khartoum. Dr. Duval followed the expedition against the Afridis.

Dr. Watt Black, after a service of nearly thirty years, has resigned the appointment of Obstetric Physician to Charing Cross Hospital, London, and has been succeeded by Dr. Amand Routh.

The last issue of the *London Gazette* contains the announcement of the appointment of Sir William Henry Broadbent, Bart., M.D., F.R.C.P., to be one of Her Majesty's Physicians Extraordinary, in the room of the late Sir Richard Quain.

At a recent meeting of the Governors of Wellington College, Sir Joseph Fayrer, Bart., K.C.S.I., was elected a Governor, and the election has been approved by Her Majesty.

Here is a bull for you, *The Medical Age* of 25th June says—"Sir James Paget, the veterinary surgeon, is very ill." A veteran, but not a vet to be sure.

Dr. Masina, a well-known surgeon of Bombay, has obtained the F.R.C.S. of London. He is not the first man from India who has gained this much-sought distinction.

Dr. F. M. Graham, the Medical Officer in charge of Jammu dispensaries, has resigned the State service, owing to ill-health, and will be shortly leaving for England.

We have reason to believe that the new military titles will not be made applicable to officers of the Indian Medical Service, who are not a Corps but a department. Their quasi civil position precludes their getting purely military titles.

It has been decided that the monument to Professor Charcot will be formally unveiled at the Salpêtrière in Paris on 23d October.

Surgeon-Lieutenant-Colonel E. Bovill, Officiating Civil Surgeon of Howrah, is allowed privilege leave for three months.

Surgeon-Captain C. E. M. Green is appointed to act as Civil Surgeon of Howrah.

The Medical Register and Directory of the Indian Empire is now ready and is open to all registered practitioners. The time should be lost to secure copies.

THE WRONG ASPECT OF THE ANGLO-INDIAN QUESTION.

DR. WATKINS, who was received with loud cheers, then said:—Mr. President, Ladies and Gentlemen I have been asked to propose a Resolution which denotes an important, though perhaps radical, change in the constitution, rules and general working of our Association.

THE PAST 20 YEARS' WORK.

For twenty years we have worked on narrow and illiberal lines, which, however, well intentionally designed, have proved unsuited to the advancement of our cause. By this assertion of a very plain and undeniable fact, I have not the remotest desire to discredit the projectors of old schemes. What may have appeared suitable to the circumstances and socio-political position of the Domiciled British Community of India two decades ago, can hardly be logically held to be suitable to-day.

HOW WE STAND TO-DAY.

The times have changed, and we must change with the times. The social questions that confronted our predecessors still confront us, and they must be solved. But the political horizon of the great Anglo-Indian question bristles with more important and more serious difficulties than ever before. Hence we are compelled to change our plans, to alter our tactics, to widen our sphere of action and to prepare ourselves for a great struggle to obtain for our community a just and equitable recognition of its political position and of its rights and privileges in common with other communities in the Indian Empire.

WHO ARE WE?

You have all doubtless acquainted yourselves with the details of the Report of the Deputation of the Anglo-Indian Associations, which waited on the Secretary of State for India in London in July last year. That Report is full of serious topics that concern the well-being of the Domiciled British Community of India. Having taken a share in this Deputation, I feel it my solemn duty to urge upon my countrymen the supreme need for a continuance of the agitation of our cause in England, so that by the exercise of political power in London, our cause will not only not languish, but secure the only leverage that will bring success to our efforts to win a proper and just recognition of our national status from the Government of India and the India Office, and the granting of those rights and privileges, which we as Britishers, and the descendants of Britishers, have a legal right to claim in common with our kinsfolk in the Home-land.

OUR PRESENT DUTY.

A plain duty lies before us to-day. Whatever may have been the political errors of the Anglo-Indian race in the past, they must not be forgotten. For our errors teach us valuable lessons, but they must not discourage nor baulk us, they must energise us to new and truer efforts, they must inspire us with zeal and enthusiasm. With the light and reasoning and experience of past years, let us redeem the present from failure, and the future of our people will be pregnant with happy results.

OUR RIGHTFUL POSITION.

It will be observed in the London *Times*' report of the Deputation to the Secretary of State for India in July last, that our people are referred to as "the Domiciled British Community of India." This is exactly what we are, Britishers all of us. Ninety per cent. of us are so by race, by nationality, and by every title that binds us to England and to its Throne. The minority of us who may be descended from

other European parentage, are European British-born subjects by assimilation, and therefore all of us are lawfully embraced under the inspiring name of BRITISH. This name is a costly heritage, and it is our legal right. By law a man claims race and nationality from his father. The admixture in Indian blood in the sons of Englishmen, Scotchmen or Irishmen, can never rob them of their inalienable national heritage. No Englishman considers himself any less an Englishman because his mother was a French woman. Britishers we are and Britishers we ever must and shall be. Once we relinquish this name and permit ourselves to be styled "Kurassians" or Statutory Natives of India, we become estranged from our proud heritage as Britishers.

THE HARMFUL INFLUENCE OF CLASS NAMES

Let me prove how this theory has been disastrously worked against us. Some years ago a member of the Bengal Secretariat thought he would coin some epithet for the new race of British descendants in India, who were fast becoming a power in the land; so he thought the word "Kurasian" would suit, and it was launched on the classical nomenclature of State documents, as the name and title of this new race. But its deep and insidious sting was ever felt as a stigma and a curse by the men and women and children who were henceforth to rally round this hybrid standard. This name once accepted, was intended to alienate the honored designation of "Britisher," and the process of isolation, ostracism and degradation, would in time have been rendered complete. Years went by, and it was found that the people called "Kurasians," though still meek and intensely loyal, were growing in numerical strength by leaps and bounds, and what was still worse, the inherent intellectual, moral and physical qualities of the race, were being exhibited to so much public advantage, that soon the distinguished and coveted positions in all the State services in which recruitment of Britishers in India was permitted, were being occupied by these self-made, sober-headed, honest, hardworking, loyal-souled "Kurasians." The credit of coining or inventing this term Kurasian, is given to the Marquis of Hastings, Governor-General of India, and to a certain Mr. METCALFE of the Bengal Civil Service. (Certain it is, however, that as far back as 1830, when Mr. RICKETTS, the first representative of the Domiciled British Community, laid our cause before Parliament, the term "Kurasian," was then staunchly objected to. Often since then, efforts have been made to dislodge this insulting epithet from official usage, but no really determined protest has ever been hurled against it. Finding that the term "Kurasian" was not sufficient to politically emasculate our people, another official cynic conceived the idea, that the "Domiciled British Community" should be induced to accept the designation of "Statutory Natives of India," under the seductive inducement that with the acceptance of this classification of our people, they should lose nothing, but rather gain the right of admission to the "Statutory Civil Service," which was about to be inaugurated for the sole benefit of "Natives of India." The so-called "Statutory Civil Service" turned out to be one of the biggest shams of the Victorian era.

THE POLITICAL WRONG DONE TO BRITISHERS IN INDIA.

From the date of the promulgation of the terms of the Government Resolution defining the designation "Statutory Natives of India," as including the whole Domiciled British Community, Europeans and their descendants who had permanently made India their home, and native Indians, the Government of India and the India Office, boldly initiated their long secretly devised plan of depriving the Domiciled British Community of India of all participation in rising to the highest positions in the Departmental Services of India.

(Continued from page 161.)
of Secretary of State, Mr. W. E. Gladstone, at the House of Commons on the 25th March, 1896. Mr. L. S. Parnell, M.P., was present and took part in the discussion, presiding.

Minister declared in this country. The status of the "coloured Secretaries and the hierarchy of the Indian Office was now on the eve of accomplishment.

WE MUST ACT AT ONCE AND NOT TOMORROW.

The official victory is not yet won, but unless our people "FORN SQUARE" and unitedly face the grave danger that now threatens to overwhelm us, unless we put forth all our constitutional strength, unless we make our voice heard in union, in clear and unmistakable and determined protest, the policy of the present Government will cast us forth from our estate and we shall indeed be degraded.

OUR CLAIMS TO STATE RECOGNITION.

Integrity, merit and ability have been our only passports to advancement in the service of our Queen and Country in all the long years of British-Indian History. By these unflinching qualities we have won position and trust and honor in the past, and now without fault, for no lawful or just reason, we are not only to lose our God-given rights in the land of our birth, in the land of our adoption, in the land in which we own and claim a rightful equality with the kinsfolk of our fathers, our fathers who fought and bled and died to win this land for England, but we are to be degraded with the brand of inferiority and subordination to our British co-workers. That this is the true interpretation of the recent edicts of the Government of India and of the India Office, may be seen by the terms of the orders which control admission to the Departmental Services of India.

THE ENGLISHMAN IN ENGLAND AND INDIA, ONE SUPERIOR THE OTHER INFERIOR.

The State has now decided and ordained that all the Departmental Services of India shall henceforth be divided into two classes one **THE IMPERIAL**, and the other **THE PROVINCIAL**. The Imperial shall be recruited in England, with the salaries of its members ranging from five hundred to as many thousands of rupees per mensem. The Provincial shall be recruited among "Statutory Natives of India," (i.e., Europeans and their descendants, and Natives), with the salaries of its members ranging from any menial sum to start with, but rising only to a few hundreds of rupees per mensem! But *subordinates*, nothing but *subordinates*, you shall ever be, because you are not *Britishers*, but *Statutory Natives of India*!! This is the tyrannical culmination of the selfish devices of the India Office and of the Government of India. Will our people sit silently under such cruel inflictions?—Never!

THE WRONG OF SUCH ACTION.

Can the Government argue in support of its conduct towards the Domiciled British Community, that the sections of its Departmental Services which it purposes officering by men from England, have not been able, honorably, efficiently and creditably filled in the past by members of the Domiciled British Community? It dare not do so, and it cannot do so if the solemn truth be told. Have not Anglo-Indians filled with infinite credit, the highest appointments in the Judicial, Educational, Administrative, Financial, Railway, Telegraph, Engineering, Medical, Survey, Political, Postal and every other Department of the State in India, and having done so, (which the records of our Secretariats will abundantly and conclusively prove), why should they be deprived of those much coveted openings for genuine ability and meritorious and faithful service? This signifies the perpetual debasement of the sons of Britons. They are ever to be the subordinates and the inferiors of their Home-bred kinsfolk. Birth and education in India have now an ominous and degrading significance, for there is now officially stamped upon them, with the great seal of the State we have so faithfully served, the impress of class inferiority. Surely this is an outrage on

the rights and privileges of the Domiciled British Community which is unparalleled in the history of British India, and which it would be disloyalty to the British name to bear in silence. In these days of universal British "Federalism," we have only to manifest grievances undisturbed, to excite a thrill of sympathetic indignation against the misdoings and unmeaning official conspiracy against the true interests of the Empire.

FALSE ARGUMENTS

The argument used by the India Office in support of this policy of importing British labor from England is, that as an employer of labor, it has a perfect right to utilize the best material it can obtain. We raise no objection to the virtue of this excellent principle, but before the value of any two commodities can be proved, they must be compared. Comparison with regard to the superior fitness of one candidate over another, can only be honestly gauged by competitive examinations, and we claim that we are able to put as good men into the field of State labor as England can, and we base this claim on the unimpeachable verdict of our services in the past. We therefore claim the right to compete in India with our British co-workers for British posts in the Higher Indian Services. It will be a cruel injustice to exclude us from such competition in India. **WE ASK FOR A FAIR FIELD AND NO FAVOR** in competition, but we will never submit to being outcasted and stigmatised, even alongside of the best and noblest of England's sons who have not the stain of birth in a tropical clime.

No better plan could have been adopted to divert the affection of a truly loyal people from a Government, which by such transparent injustice, is bound to lose the respect and sympathy of a large and growing section of its subjects, whose power and importance are little known and understood and who, for their hitherto unswerving fealty to their rulers, have been rewarded with neglect and contumely.

The varied services of the Anglo-Indian or Domiciled British Community in the administration of India, were faithfully and graphically recorded by the Deputation to the Secretary of State for India, in their testimony at the India Office in London, on the 23rd July 1897.

Our Association has recently approached His Excellency the Viceroy to communicate to us the decision of the India Office in regard to the important matters concerning our community, which were placed before Lord George Hamilton by our Deputation in July last. The Viceroy in reply has stated, that the whole subject is receiving the serious consideration of the Government, but we have received no further light on this question.

WHAT MUST BE DONE.

Read the Report of our London Deputation and then decide if the recent policy of the Government of India and of the India Office towards the Domiciled British Community is not worthy of unqualified condemnation.

In view of the disabilities and grievances under which we labor at the hands of the Government, certain steps are necessary:—

1. Our combination under one standard and that standard to bear the name of our true and lawful national position.
2. A clear declaration of our disabilities and grievances to the Government of India and the India Office.
3. A solemn and fixed determination to adopt any and every constitutional means to induce the Government to acknowledge our rights in common with the imported British subjects.

1. **OUR STANDARD.** OUR ASSOCIATIONS all over the country, should bear one definite name, such as will signify

...of our community, who may be either British, descent, or the small minority who are of pure European blood, or descended European, and who are permanently domiciled in India, all forming important portions of our British Empire in this land. It is proposed to designate our UNION, "THE IMPERIAL ANGLO-INDIAN ASSOCIATION or THE ASSOCIATION OF THE DOMICILED BRITISH COMMUNITY OF INDIA" having branches all over the country. Each Branch would have its own central working bureau, but we should endeavor to form a NATIONAL COUNCIL, having representatives from each of the Branches. In the phrase "Domiciled British Community of India" we have not only a correct legal definition of our people and of our socio-political position, but we have a name that will charm the president of Britishers and other Europeans to our standard. The absence of a definitive British title for our Associations, has been and is the great stumbling-block to our union and cohesion. Distinctions of color are bridged over by a NAME, for that name evokes a spirit of PATRIOTISM and inspires TRUE UNITY. We should bear this vitally important fact in mind, for in our present selection of a NAME for our people and our ASSOCIATIONS, we must be guided by the bitter experiences of the past, to shape the political foresight of the near future. Then we have the term IMPERIAL. This bears the impress of loyalty. To-day the political atmosphere of England is charged with the spirit of IMPERIALISM and this word is now used to convey the idea of combination and cohesion on the part of England's world-wide Colonies and territorial possessions with the mother country. Hence we are not adopting a name that belongs only to the Imperial Government, but one which is the common national property of every loyal true-hearted body of Colonists all the world over. Besides the term IMPERIAL denotes our policy as one of loyal unity with our rulers and with the Empire of India. In no way can this word 'Imperial' be correctly pronounced as impolitic in connection with the designation of our Associations.

2 OUR DISABILITIES AND GRIEVANCES may be focussed under the following heads :-

1 OUR EXCLUSION FROM the higher departmental appointments of India, now being reserved for imported Englishmen in the grades known as THE IMPERIAL SERVICE

2 OUR EXCLUSION FROM the benefits of HIGHER STATE EDUCATION, which are freely given to Natives, in the form of State built and State-supported Colleges in all the Presidency and Provincial Towns of India

3 OUR EXCLUSION FROM an important avenue of labor—THE SERVICE OF ARMS—which is freely open to the natives of the country. While the Government accepts the gratuitous service of no less than 85,000 of our community as volunteer soldiers, it refuses to accept us as paid soldiers, and to form local regiments from our people, who are willing to accept exactly similar terms and tests for admission to the army, as are applied to British soldiers in England. In order to show the enormous military strength of the Domiciled British Community of India, every man capable of bearing arms should enrol himself as a Volunteer. What a silent but eloquent estimate of our political strength could be exhibited by a force of 500,000 citizen soldiers. In this connection it is of vital importance to our Cause that our people join heartily in the Volunteer movement. Let the strength and power of our people be shown in BAYONETS and let us point to them in the motto of the Volunteer movement, "DEFENCE, NOT DEFEATANCE!"

4 OUR EXCLUSION FROM ENLISTMENT IN BRITISH

ARMY. We are not asking for equality, but for equality is allowed on a par, and for as an insult to our people. All restrictions should be removed.

5 THE LOSS OF OUR HOMES AND TERRITORIES AS RENT-FARMERS and the unlawful classification of our people as "Statutory Natives of India," with all its attendant atrocities, degradation and perpetual subordination.

6 THE CONSTITUTIONAL MEANS TO BE ADOPTED :

First and foremost, the Domiciled British Community throughout the Indian Empire must be roused to a very keen sense of the political dangers that threaten its existence and that render its prospects extremely gloomy indeed. This must be done by a political manifesto, setting forth the whole circumstances of their case, distributed broadcast over the length and breadth of the country. Secondly, the keenest and the most persistent energetic efforts must be made to unite the whole community into one solid Association. Each large city in the Presidencies and Provinces must be made the centre of unflagging activity to enlist members and to raise funds. Money is the *sine qua non* of this movement, the sinews of war for every forward movement we take in our great socio-political campaign. Recent calculations as to the numerical strength of the Domiciled British Community go to prove that it is over a million strong. Our official critics are eternally harping on the poverty and helplessness of our community. They say that a Britisher or a European born and educated in the Tropics, or those of us of mixed descent similarly situated, are deficient of backbone and of those moral, physical and intellectual qualities that they claim are the unquestionable possession of the English-trained subjects of our Queen. It is very easy to say what is false, but is very difficult and often most inconvenient to prove an off-hand statement to be a fact. We defy our critics to PROVE their statements. Where is the country in this world that has not its moral, intellectual and physical units? Anglo Indians are no exception to the rule. This long fostered and untruthful libel against our race must however, be proved to be untrue. Our rulers must be made to feel that it is untrue.

UNITE, UNITE, UNITE

Were our community to unite as one man, with a force of 500,000 effective volunteers ready to back its assertions and its claims, our official critics would be silenced most effectually. The days of humble supplications have gone by. The era of manly independence has dawned. Let us seize the opportunity and henceforth demand our rights as men.

THE NEW ASSOCIATION

In Calcutta, we propose by our new constitution and rules to inaugurate the IMPERIAL ANGLO-INDIAN ASSOCIATION on a thoroughly representative, sturdy and lasting basis. It aims at true representation. It demands practical interest and energy on the part of its representatives. It seeks individual co-operation, and aspires to universal unity. You will observe that in order to be a Director of the Association the aspirant must have the support of one hundred members and he must bring to the common purse of the Association Rs. 100 yearly. In plain words he must enlist the sympathy and interest of one hundred people in their own cause and he must collect from them 1 Re. per head per annum. Calcutta has a domiciled British population of over 27,000. I think it will be an easy matter to find 100 manly, enthusiastic members, who will immediately undertake the responsibility and the honor of becoming Directors of our Association. In less than six months, by the faithful and earnest carrying out of our plans, these 100 Directors will each have found 100 supporters, so that we can reckon on having, be

that the State, in its administration, should be determined to win success. We ask you today in all earnestness to support our scheme with your individual and enthusiastic determination to make it a success. Each Presidency and Province will in its turn adopt our scheme, I am sure, and in a short time the overwhelming of the latent political power of the Domiciled British Community will be manifested both to the Government of India, and to that strong-hold of prejudice and misadministration—the India Office of London.

Having organized our Association throughout the country, we must concentrate our energies in ventilating our claims on British soil, before the British people and in the British Parliament, for if British India's political battles are to be won, they must be won by the effort that shall emanate from the hearts of our kinsfolk in Great Britain and from that justly revered Tribunal of Equity, the Parliament of England. (Loud Applause).

**LETTER FROM THE COUNCIL OF THE IMPERIAL
ANGLO-INDIAN ASSOCIATION TO ALL MEMBERS
OF THIS DOMICILED BRITISH COMMUNITY
OF INDIA.**

TO OUR FELLOW-COUNTRYMEN IN INDIA

FRIENDS,—The Council of the Imperial Anglo-Indian Association feels that the time has come when the Domiciled European Community must all be inseparably united in defence of our common interests, our rights, our socio-political position, and our prospects in the land, which we either from choice, from business connections, or from force of circumstances have made our temporary Domicile or our permanent home. It is keenly felt that as a class the domiciled British and European Community and their descendants in India, labor under many disadvantages in comparison with the Native Indian community, and the State-imported European. The native Indian by force of persistent agitation has compelled the Government to acknowledge his socio-political position, and thus he has a seat in the Councils of the Empire, and a voice in legislation in all that concerns the well being of his countrymen. He finds a place of honor in the highest tribunals of the country, and his social and material welfare receive the most generous attention and assistance of the Government. For do we not find the whole Empire of India studded with primary and high schools and handsomely equipped colleges officered by highly-paid and highly cultured European professors, all supported entirely by the State for the exclusive use of Hindus and Mohammedans. Do we not also find the surplus population employed by thousands in the Indian Army, and does not the expenditure of millions of money in Relief Works, prove the anxious concern of our Government for the well being, contentment and happiness of our Indian fellow subjects? While we mention these evidences of State favor towards a large and important section of the inhabitants of this country, we have not the smallest desire to see our Indian brethren deprived of any of the blessings of good and righteous government. But good and righteous government demands an *equality of rights and privileges*, FAIR PLAY, A FAIR FIELD AND NO FAVOR, and every subject has a right to demand this at the hands of the Government, and it is his duty to himself, to his country, to his people, to his home and to his family to see that he gets it. He must not be satisfied until the laws of the land are equitably and righteously administered, so that his community and his people hold a position, both social and political, of perfect equality, in all that relates to his rights and privileges in the land in which he lives.

Throughout the Government of India, the Domiciled British and European Community and their descendants find that the Government, in its administration of the State, to import European labor into all the Governmental departments, with a cruel, crushing and systematic attempt for the fitness of the European material which is to be found in India. It is the claim of the Domiciled British and European Community that it can provide suitable candidates for every appointment in India which the State decides should be filled by persons of British or European blood or descent. It claims that the history of the British Indian administration in the past more than justifies this claim, and it now urges that it has a right to demand a fair share of all British appointments in India in open competition with imported British labour. It demands that neither prejudices nor favor should decide the fitness of candidates, but that comparison of merit as gauged by fair and honest competition, be the only test applied. It further protests that the Domiciled British and European Community and their descendants suffer under very various disabilities and hindrances to advancement in the public services of India as compared with imported British labor; for while the imported Britisher has highly equipped Colleges, such as Coopers' Hill and others open to him and maintained at India's expense, the Domiciled Britisher has no colleges of such standing and educational facilities open to him. The Engineering College of Roorkee, although not so efficiently equipped as Coopers' Hill, has, in spite of its disadvantages, turned out some of the best Engineers and Surveyors that India has ever seen. There is no Military College in India, and no facilities for opening up a military career for our lads. Territorial or Local European Regiments are not allowed by the State, though over 15,000 of our people are loyally giving their time and their services to the Government in defence of its power and prestige as Volunteers. We have no facilities for training our boys as soldiers, nor any inducements that they should adopt the profession of arms. Compare this disability of the domiciled Britisher with the numerous military training schools in England, and we realize the hardship and injustice of our position. There is no Naval College, and not a single Training-Ship in Indian waters for educating our boys for a career at sea, while training-ships, kept up at India's expense, are maintained for British lads intended for work in the Indian Marine and the Pilot Service. This presents another important disability.

These are some of our disabilities, and for their removal, the Imperial Anglo-Indian Association will work with all its energy and ability. There are numerous social questions that also need public attention, and these, too, will be fully dealt with as time and opportunity permit. Meanwhile the Council earnestly pleads for the united efforts of our people throughout India as the only means of ensuring victory to our cause. If we **UNITE AS ONE MAN**, if we show a very strong numerical front to the Government, if we indicate by our policy that we shall never cease to agitate our cause, nor relax in our determination to have our just and righteous claims conceded by the Government, both here and in England, we shall find all our hopes and aspirations as a free, independent and united community more than fully realized in a short space of time.

No member of the Domiciled British and European community should hold aloof from the Imperial Anglo-Indian Association. Whether servants of Government, or engaged in private industry, we may have sold our talents, our labor, and our time, but we have not enslaved our souls, nor bartered away our liberty, nor renounced our manhood. We

THE COUNCIL OF THE IMPERIAL ANGLO-INDIAN ASSOCIATION. MEMORANDUM OF ASSOCIATION OF THE IMPERIAL ANGLO-INDIAN ASSOCIATION.

1. The name of the Society is "The Imperial Anglo-Indian Association."

2. All members of the Dominated British and other European Communities and their Descendants in India may become members of this Association.

3. The Head Office of this Association shall be at Calcutta, with Branches all over the Indian Empire.

4. The aim of this Association shall be to advance the interests of the classes described in clause 2, as one of the surest means of consolidating and popularizing British power in India and preventing the grave political dangers and complications foreseen by many British statesmen in India.

5. The Governing body of the Association in Calcutta shall consist of a Council comprising—

- (a) 1 President,
- (b) 4 Vice-Presidents,
- (c) 12 Members,

all of whom shall be elected annually.

The first Council of the Association shall be :—

4. The objects of the Association are—

a.—The secure representation for its Community in the Councils of the Indian Empire on terms of equality with other communities.

b.—To secure equality with other communities in the various spheres of Government activity in the country, and especially in matters of education, industrial promotion, and social welfare.

c.—To promote the material, intellectual, moral, and social advancement of its Community and to protect the rights and status of British and European Residents in India and their descendants, and to further their economic interests by every possible constitutional means.

d.—To adopt or promote such philanthropic, economic, industrial, educational or other measures as may be best calculated to better the condition of the various classes of its Community.

e.—To found and maintain libraries, or reading-rooms for general use among the members, and to establish a newspaper, or magazine to advocate the cause of its Community.

f.—To acquire lands, lands, buildings and other movable property, and to hold the same for, and in the interests of, the Association.

RULES OF THE IMPERIAL ANGLO-INDIAN ASSOCIATION.

(Registered with the Memorandum of Association.)

THE NAME AND OBJECTS OF THE ASSOCIATION.

1. The name and objects of the Association are those defined in the Memorandum of Association.

MEMBERSHIP.

2. All Members of the Dominated British and European Community and their Descendants, of either sex, over the age of eighteen years, residing in India, shall be eligible as Members.

3. Persons desirous of entering the Association shall fill up and sign the following form, which shall be forwarded to the Secretary of the Association :—

I hereby agree to become a Member of the Imperial Anglo-Indian Association (or the Association of the Dominated British and European Community and their Descendants in India), and I undertake to support its cause to the best of my ability. I further agree to pay a sum of one rupee annually to the funds of the Association.

Name _____

Occupation _____

Address _____

Dated this _____ 19__.

4. Membership does not involve the payment of any fixed subscription; but Members may contribute any sum at any time to the funds of the Association. The sum paid to the Association by each Director shall, however, always be reckoned as legal tender of subscriptions for and on behalf of each and all of his constituents.

PRIVILEGES OF MEMBERS.

5. Members shall have the following privileges :—

(a) They may attend all General Meetings.

(b) They may speak and vote at such meetings.

(c) They may have access to the office and premises of the Association, subject to any restrictions regulations imposed.

(d) They may vote on all questions referred to the Association at large.

(e) They may fill any paid or unpaid offices of the Association.

(f) They may participate in any other advantages arising out of the working of the Association.

1. The executive control of the Association shall be vested in a Council, consisting of a President, four Vice-Presidents, and twelve Members, to be elected by the Directors, of whom there shall be not less than fifty, from among themselves. The Council shall hold office for one year, but its Members shall be eligible for re-election.

ELIGIBILITY OF DIRECTORS

2. Any Member of the Association shall be eligible for the position of Director. It shall be incumbent on such Member to prove his interest in the Association, his right to be considered representative, and his ability to help the cause, by furnishing the Council, through the Secretary, with a bona-fide list of one hundred members who support his candidature, such members not being borne on the list of any other Director. He shall also pay to the Treasurer of the Association on or before the first day of March, for each year of his Directorship, the sum of Rupees, one hundred, or one Rupee for each Member, which he may subscribe himself or collect from his constituents, and such sum shall be reckoned as legal tender for and on behalf of each of his one-hundred constituents.

ELECTION OF COUNCIL AND DIRECTORS

9. The first Council of the Association shall be formed of the Members composing the Board of Directors of the E & A-I. Association at the time of the registration of the I A-I. Association into which the E. & A-I. Association shall thereby be merged.

10. It shall be the duty of the Council in office at the time of the receipt of any application from any Member of the Association claiming to be recognised as a Director under Rule 8, to satisfy themselves that the conditions of the said rule have been fulfilled.

11. During the first week of March in each year, the Directors shall meet and elect the Council from among their own members by vote. The elections of the President and Vice-Presidents shall take place at the same time and place and in the same way.

12. Notice of not less than seven days shall be given to every Director of the election of the Council, and this by advertisement in the newspapers or by letter; and it shall be competent to the Council, for sufficient reason, of which they shall be the sole judges, either to postpone the election in the first instance or to adjourn it after it has been once fixed; provided that the postponement or adjournment in no case can put off the election beyond the 20th day of March; and that due notice thereof be given to all Directors.

13. Vacancies occurring in the Council between the regular elections shall be filled up by the Council from among the Directors.

14. A Member of the Council shall cease to hold office as such—

- (a). If he hold any place of profit under the Association,
- (b). If he absents himself from three consecutive ordinary meetings of the Council without assigning sufficient reason in writing,
- (c). If he shall send in his resignation to the Secretary in writing.

15. The Directors shall personally interest themselves in all matters that pertain to the aims and objects of the Association. To this end they shall be formed into Committees dealing with subjects kindred to the various objects of the

- (d). If he shall be elected to any office of profit under the Association,
- (e). If he shall be elected to any office of profit under the Association,
- (f). If he shall be elected to any office of profit under the Association,
- (g). If he shall be elected to any office of profit under the Association,
- (h). If he shall be elected to any office of profit under the Association,
- (i). If he shall be elected to any office of profit under the Association,
- (j). If he shall be elected to any office of profit under the Association,
- (k). If he shall be elected to any office of profit under the Association,

- (m). If he shall be elected to any office of profit under the Association,
- (n). If he shall be elected to any office of profit under the Association,
- (o). If he shall be elected to any office of profit under the Association,
- (p). If he shall be elected to any office of profit under the Association,
- (q). If he shall be elected to any office of profit under the Association,
- (r). If he shall be elected to any office of profit under the Association,
- (s). If he shall be elected to any office of profit under the Association,
- (t). If he shall be elected to any office of profit under the Association,
- (u). If he shall be elected to any office of profit under the Association,
- (v). If he shall be elected to any office of profit under the Association,
- (w). If he shall be elected to any office of profit under the Association,
- (x). If he shall be elected to any office of profit under the Association,
- (y). If he shall be elected to any office of profit under the Association,
- (z). If he shall be elected to any office of profit under the Association,

POWERS OF THE COUNCIL

16. The Council may, from time to time make, amend, suspend, or repeal By-laws for the regulation of the affairs of the Association, and generally for the management of its affairs and property.

17. The Council may exercise all such powers, and do all such acts as might be exercised and done by the Association, save such as are restricted to the Association by act XXI, of 1860. Neither the Council nor any Member, Director, Officer, or Agent of the Association shall have any authority to involve any member in any personal responsibility touching the administration of its affairs.

PROCEEDINGS OF THE COUNCIL AND OF ITS COMMITTEES

18. The Council shall meet monthly, or oftener, if necessary, for the despatch of business, and five Members shall form a quorum.

19. The President, or, in his absence, a Vice-President, or five Members of the Council, may at any time call a Special Meeting of the Council, giving due notice of such meeting to each Member through the Secretary.

20. The Council may appoint Committees, consisting of such Members of their body, or of the Directors of the Association, as they think fit, to consider and report upon any question that may arise in connection with the aims and objects of the Association. One of such Committees shall be the Standing Committee of Finance, consisting of the Treasurer and at least two Members of the Council. All such Committees shall elect their own Presidents.

21. All Committees shall submit their reports in writing to the Council, through the Secretary.

22. All Proceedings of the Council and of Committees shall be reduced to writing, and shall be signed by the Chairman of the Meeting at which the same are passed. The proceedings of the Ordinary Monthly Meeting shall be brought up for confirmation at the next Ordinary Meeting of the Council.

23. Nothing in the Proceedings of Council Meetings shall be considered invalid, on account of any technical defect in the constitution of the Council or in the election or appointment of any Member thereof.

ORDINARY AND SPECIAL GENERAL MEETINGS OF THE ASSOCIATION

24. The Annual Meeting shall be held in the first quarter of each year, and twenty-five Members shall form a quorum.

25. One week's clear notice, specifying the place, day, and hour of such Meeting, and in case of special business, the nature of such business shall be given to the Members of the Association, either by advertisement in the Calcutta papers, by letter, or in any other way as may be prescribed by the By-laws, but the non-receipt of such notice by any Member shall not invalidate the proceedings of such meeting.

26. All business at Annual Meetings shall be deemed special, with the exception of the adoption of the Annual Report with Financial Statement, and the declaration of the election of Members of the Council.

30. The Council may, whenever they think necessary, and shall, upon a requisition signed by not less than fifty Members of the Association registered in Calcutta, convene a Special General Meeting, always provided that no matter which had been decided by an appeal to the Association at large shall be re-opened within twelve months at such Special General Meeting.

31. Any such requisition must clearly express the objects of the Special Meeting to be called, and must be delivered to the Secretary fifteen days before the date at which it is desired to hold such Meeting. No business shall be transacted at such Special Meeting, unless at least twenty-five Members, other than Directors and the Requisitionists are present.

32. If a quorum of Members be not present at a Special General Meeting thirty minutes after it is summoned, it shall be adjourned; and if a quorum be not present at the Adjourned Meeting, it shall be dissolved.

33. If a quorum of Members be not present at an Annual General Meeting, twenty minutes after the time appointed for its commencement, it shall stand adjourned to a convenient day in the following week, and if at such Adjourned Meeting a quorum of Members be not present, the Members then present shall form a quorum—such adjournment being notified in the usual way.

34. The President, or, in his absence, one of the Vice-Presidents, shall preside *ex-officio* at every Meeting of the Association, convened in accordance with the above rules, provided always that the President or a Vice-President be not of the number of requisitionists for a Special Meeting, in which case or in the absence of Presidents and Vice-Presidents, the Meeting shall elect its own Chairman.

35. At any General Meeting, a declaration by the Chairman that a resolution has been carried, and an entry to that effect in the Book of Proceedings of the Association, shall be sufficient evidence of the fact.

36. If a poll or ballot is demanded the same shall be taken in such manner as the Chairman directs, and the result of such poll or ballot as declared by the Chairman shall be deemed to be the Resolution of the General Meeting.

37. When any question arises, which, in the opinion of the Council, should be referred to the whole body of Direc-

tors of the Association, or which involves the repeal or alteration of, or the addition to, any of the Rules of the Association, the votes shall be taken by voting papers transmitted to them by post or otherwise, by the Secretary to the Association. The question so referred will be decided by the majority of votes received.

FUNDS AND ACCOUNTS OF THE ASSOCIATION.

38. The funds of the Association shall be lodged in the Bank of Bengal in the name of the Council. Any surplus exceeding the sum required for the working expenses shall be invested in Government Securities, or any other stock approved of by the Council. Withdrawals from such funds shall be by cheque signed conjointly by the Treasurer and the President or a Vice-President of the Association.

39. The Accounts of the Association shall be kept by the Treasurer, supervised by the Standing Committee of Finance. A monthly financial statement shall be presented by the Treasurer to the Council.

40. The books of account, together with all deeds, vouchers and documents belonging to the Association, shall be open to inspection by the Directors at the Office of the Association, subject to any reasonable restriction that may be imposed.

41. At the Annual Meeting, the Council shall lay before the Association an Annual Report of working of the Association during past year, a duly audited statement of the income and expenditure for the year ending the previous 31st December, and also an audited balance sheet, containing a summary of the assets and liabilities of the Association made up to the same date.

42. The Accounts of the Association shall be examined and their correctness certified by an Auditor appointed by the Council. No Director or person interested in any pecuniary transaction of the Association shall be the Auditor.

BRANCH ASSOCIATIONS.

43. The Council may affiliate Branch Associations on such terms and conditions as may be deemed advisable in accordance with the Constitution of the Imperial Anglo-Indian Association.

A NATIONAL COUNCIL.

44. A National Council shall be formed, consisting of representatives from all the Branches of this Association and other kindred associations.

Rectal Aspiration.

In the *Gazette Médicale de Paris*, 28th May 1898, Dr. MARGEL BAUDOUIN, has published an extraordinary case—the second on record—of rectal aspiration, or, as he terms it, *petomanie*. He published the first case in the *Semaine Médicale*, 30th April, 1892. The subject was a man who could first aspirate by the anus and then expel air or liquid in large quantities. He was in the habit of giving public exhibitions of his powers. The second case was that of a married woman aged about thirty years, the mother of five children. For a long time she had noticed the facility with which she expelled gas from the large intestine, and thinking that she was affected with some malady, she confided her troubles to a friend who had attended some of the exhibitions just mentioned. The latter assured her that instead of disease she had a fortune—in her abdomen! Accordingly she attended the exhibitions and soon learned enough to embark on this strange profession. Having aspirated a large quantity of air into the intestine she expelled it, producing characteristic sounds of various tones and intensities in imitation of laughing, whistling, the quacking of a duck, &c. These sounds were no doubt due to a power acquired over the anal muscles similar to that over the laryngeal. She introduced into the anus a cannula connected with a tube having a receptacle at the other end into which was placed a lighted cigarette. The cigarette burnt brightly when she aspirated; the smoke was driven out in a cloud when she expelled the air. But her powers appear to have been inferior to those of her model to which even the *Times* devoted an article. He could imitate the sound of cannon, musketry, thunder, the violin, the trombone, and the human voice; and he could even sing in this extraordinary way! However, there is nothing new under the sun, for in the writings of St. Augustine there is a description of these very powers. How is the aspiration of the air performed? Dr. BAUDOUIN, observed that with closed glottis the man made a strong inspiratory effort, attended by great depression of the abdominal wall and of the supra-clavicular regions. Negative pressure would be thus produced in the abdomen, which would be enlarged by the elevation of the lower ribs and by the upward movement of the diaphragm towards the thorax. Dr. BAUDOUIN, describes the auxiliary muscles of inspiration and probably the diaphragm as assisting in the action. The latter supposition cannot be correct. Contraction of the diaphragm would prevent, not assist, the action. With the inspiratory effort there must be, we should think, relaxation of the sphincter ani. M. BAUDOUIN compares this abnormal power to that possessed by certain individuals over the muscles of the external ear. But a much closer parallel is furnished by cases described by Dr. JOHN WYLLIE in the Edinburgh Hospital Reports, 1896, of neurotic individuals who acquired the power of creating by muscular action negative pressure in the œsophagus, and thus sucked air into the stomach. In *The Lancet*, of 1st August 1896, Dr. G. A. SUTHERLAND, published a remarkable case of this kind. The power of swallowing air possessed by one of BURNUM's "freaks," who could rapidly pass from the appearance of emaciation to corpulency to which we referred in *The Lancet* of 12th Feb. 1898, may also be mentioned. But if the air was really swallowed and not aspirated the action is of a different kind and is distinguished by Dr. WYLLIE from air sucking.—*Lancet*.

Diabetic Albuminuria and its Treatment.

Two great ætiological varieties of diabetic albuminuria are distinguished by Dr. L. GORDARD (*La Presse Médicale*):—(1) a functional albuminuria may be met with in four different conditions—(a) simple fatigue of the kidney, (b) phosphaturia, (c) organic diaminisation and (d) hyperchlorhydric dyspepsia—and if neglected may pass on to (2) lesional albuminuria which corresponds with nephritic lesions such as BRIGHT'S disease, fatty emboli, amyloid degenerations, abscesses, renal tuberculosis, renal hypertrophy, EMERSON'S kidney, EBERMANN'S cellular necrosis and especially interstitial and parenchymatous nephritis. Mild albuminuria is almost always functional, grave ones rarely so, and many functional albuminurias develop into nephritis.

The treatment of lesional albuminuria is the same as that of BRIGHT'S disease and the diabetic condition is not taken into account, but in grave functional albuminurias the diabetes and albuminuria must be alternately treated, allowing *three* consecutive days to either; where as in the milder functional albuminurias anti-diabetic diet must be rigidly enforced and antipyrin and bicarbonate of sodium administered till the glycosuria diminishes when sulphate of quinine and sodium arseniate should be given. In the phosphatic condition the diet and arsenial portion must be accompanied by pills of Ext. Chincona and Quinine sulph. for 10 days when they are replaced by the glyco-phosphates and later by the hypophosphites milk. Bouillon and appropriate diet must restore the saline deficient in albuminuria complicated with organic demineralization and independently of the medical treatment of the hyperchlorhydria. Albuminuria of dyspeptic origin may be alleviated by giving very small quantities of food at very frequent intervals.

Treatment of Exophthalmic Goitre.

FROM the days of REUBEN till now, belladonna has been capable of diminishing the secretions of the pharyngeal, salivary and thyroid glands, and the occasional success attending thyroidectomy in GRAVES' disease indicate that in many if not all cases, disturbance of secretion in the thyroid gland lies at the bottom of the clinical phenomena manifested. Ablation, partial or complete, has been sufficiently fatal to demand some means of diminishing the exaggerated secretory activity of the gland. Hence various forms of section of the cervical sympathetic have been advocated and practised, and M. JABOULAY has more than once shewn that paralysis of the fibres of the cervical sympathetic ameliorates the symptoms in exophthalmic goitre.—*Lyon. Méd.*

Nervous Dyspepsia.

SINCE Carlsbad waters, which give very good results in hyperacidity of inflammatory origin are badly borne in nervous dyspepsia which is sometimes complicated by atony of the stomach and a certain relaxation of its walls and as it is not always easy to separate hyperacidity and acid gastritis from nervous dyspepsia in which hypersecretion may also occur, ROSENHEIM urges that great care must be taken in diagnosing nervous dyspepsia which (1) is not so common as assumed it is (2) a disease by itself chiefly a sensory neurosis (3) often impairing the motor and secretory functions of the stomach and (4) mostly existing along with other nervous manifestations, in which it is of the first importance to treat the general condition and the exciting cause; but (5) it is wrong to assume that it is a symptom of neurasthenia and (6) the symptomatic treatment of the stomach symptoms is of great value in nervous dyspepsia.—*Brit. Med. Jour.*

SURGERY.**Infective Diseases of the Urinary Passages; Cystitis.**

As the result of long investigation, ROZING of Copenhagen classifies cystitis into the (1) Catarrhal or non-suppurative ammoniacal and (2) the suppurative ammoniacal and (3) suppurative acid forms. In the first the symptoms, such as painful and frequent micturition, tenderness over pubes, &c., which are almost entirely local, are caused by non-pyogenic organisms which attack, not the mucous membrane, but the urine which they render alkaline and turbid, and make it deposit a glairy or pus-looking sediment rich in phosphates, urate of ammonia, vesical epithelium, bacteria and occasionally leucocytes and red blood corpuscles. The contact of this ammoniacal urine with the mucous membrane produces symptoms of irritation or inflammation that rapidly subside under boracic acid or any other agent that will neutralise the alkalinity of the urine, and the bacteria may be dispelled by a single injection of 1 or 2 per cent. silver nitrate solution. (2) Complications such as retention, stricture, tumour, stone, which do not themselves cause it, naturally influence the duration and result of suppurative ammoniacal cystitis, which is most usually due to pyogenic infection by instruments passed into the urethra, whence in the majority of instances the pyogenic organisms reach the bladder, though in a few cases they may be derived from the kidney or the renal pelvis; but the symptoms and progress of the cystitis are much influenced by the virulence and multiplication properties of the particular organisms that may be present. The most common of these organisms are:—*Bacillus longus uree*, *B. Crassus*, *Cocciobacillus* and *diplococcus uree*, *Proteus hansen*, *Bacillus alba* and *flava*, *staphylococcus albus*, *aureus* and *uree* which may exist separately or be associated with the colon bacillus. In either case complete lavage of the bladder with one per cent. silver nitrate solution and rinsing with sterilised water is the best local treatment which should be accompanied by the exhibition of the usual internal remedies, of which boracic acid is the most valuable, but cases complicated by lesions of the kidney or bladder must be specially treated. (3). The last form is for the most part due to the tubercle bacillus, but may also be caused by other microbes, such as the gonococcus, colon bacillus, streptococcus pyogenes &c. which reaching the bladder from the posterior urethra or by the ureters from the kidney, set up symptoms peculiar to themselves and diagnosis has to be made from prostatitis and posterior urethritis aided by bacteriological examination to determine the microbes concerned. In uncomplicated cases the irrigation with silver nitrate is most useful, when aided by salves and diuretics, but in advanced cases of tubercular cystitis with ulceration of the mucous membrane operative interference is necessary.—*Edin. Med. Jour.*

Chronic Diphtheria.

A few days after recovery from facial erysipelas a girl, aged 19, found an ulcerated patch on the right side of her palate, the glands were enlarged and her temperature 108.1 F. while virulent diphtheria bacilli were found in the exudation which extended itself to the posterior pharyngeal wall, the naso-pharynx and right nostril, but that the fever subsided and there was no albuminuria. Four weeks later there was definite paresis of the right half of soft palate and virulent diphtheria bacilli were constantly found in the exudation, which varied its position but diminished in intensity. Dr. JAMES injected her with 1500 units of diphtheria serum

which had no effect on the lesion while topical applications also failed. Lactic acid destroyed the exudation rapidly but it was found again and growing fibro-parasitic still contained diphtheria bacilli, though there were no general symptoms. Five months after its onset the exudation disappeared and the infiltration of the mucous membrane began to diminish.—*Contrab. f. ian. Med.*

Successful Removal of a large Pedunculated Accessory Lobe of the Liver.

A WIDOW, set 88, who had had 4 children and 8 miscarriages in her ten (10) years of married life, consulted Dr. CHRISTOPHER MARTIN for a large painful swelling accompanied with a nasty feeling of fullness and weight in right upper abdomen as well as back and bouts of colicky pain and bilious vomiting, chills and profuse perspiration. Her bowels and urinary functions were normal. The heart and lungs were healthy and as nothing abnormal could be detected *per vaginam* the diagnosis was doubtful as to whether the swelling (which was remarkably mobile, in all directions) was a tumor of the (a) kidney (b) liver or gall bladder (c) mesentery or (d) ovary. Exploratory incision running over most prominent part of tumor, for five inches downward from right costal margin revealed a smooth green mass depending from a highly vascular pedicle (4 inches wide and 8 inches long) which was attached to the under surface of the anterior border of the liver and was composed of some fibrous tissue enveloping the cystic duct and numerous huge arteries and veins which passed to the under surface of the liver, but there was no continuity of the glandular substance of the liver, the substance of the tumor, which was quite free from inflammatory adhesions to the surrounding parts from its hepatic border down to the pelvic brim where the lower edge of the tumor dipped. The liver proper was somewhat small but perfectly normal in shape and its round suspensory and lateral ligaments had no connection with the tumor, which could be moved freely about the abdomen. But as the gall bladder was firmly attached along the inner half of the anterior surface of the tumor whose peritoneal capsule was very much thickened, it had to be extirpated together with the tumor and a portion of the cystic duct. The abdominal wound, which was not drained, was closed with interrupted silkworm gut sutures and the patient who made an uneventful recovery, left her bed on the 16th day and was discharged from hospital on the 22nd day after the operation, since when (nearly 2 years now) she has kept good health except for a slight tendency to diarrhoea. There was not so much as a trace of any bile ducts in the extirpated tumor which was an avoid body weighing 80 ounces and measuring 9.5 inches at its longest and 6 inches at its shortest diameter.—*Brit. Med. Jour.*

Egyptian Eunuchs made to order.

IN Egypt, castration is at present performed on boys from seven to ten years old, by the monks of certain Coptic convents, who reap a good profit by supplying the harems of wealthy Mussulmans with some of their mutilated victims. The operation is made in two different ways, and I am sure of these facts. The first operative method consists in cutting off with a razor the sexual parts as near as possible to the pubic region, carrying away in a single stroke both the penis and the scrotum. Then the patient is buried, almost up to his neck, in some fine and dry sand for the purpose of staying the hemorrhage. After four or five days the sufferer is dug out and the wound is dressed with a few rags sprinkled with oil.

The second operative procedure consists in dividing or rather in crushing the spermatic cords and the penis by means of a strong twine whose extremities the operator pulls apart with all his might. The sufferings of the child are, then, horrible, but hemorrhage is not to be feared so much in this case. The sufferer is, therefore, not buried in sand and his wound is dressed with acacia bark, which is rich in tannin. But in either of the two procedures entailing these barbarous mutilations, two-thirds of the children succumb.—*Med. & Surg. Rep.*

OBSTETRICS AND GYNECOLOGY.

Perforation of the Uterus while Curetting.

At the Berlin Medical Society, M. DUKASIAN showed a uterus and made the following remarks.

"The uterus that I present to you was extirpated per vaginam; it is as you see the seat of a perforation.

It comes from a woman who suffered from very profuse uterine hemorrhage after a miscarriage.

Thinking that this was due to retention of portions of the placenta the doctor in attendance curetted the uterus but without success. I repeated the operation but did not succeed in checking the hemorrhage.

The os was then dilated with a "tent" and with the finger I succeeded in removing the placental debris, the hemorrhage however continued as profusely as before.

The life of the patient was threatened by the excessive loss of blood. So that I resorted to the extirpation of the uterus which was done without difficulty according to LANNAU's Method. Recovery was rapid.

You observe that the left wall of the uterus is injured, and an examination of what was removed by the curette revealed some of the uterine muscular fibres mixed with placental debris. It is possible that in this case the placenta was in an abnormal position and that the wall of the uterus was thin.

In an obscure case like this I think that it would be better to substitute dilation for curetting.—*La Sem. Med.*

Failure of Midwives in Asepsis.

To prevent grave errors such as imperfect cleanliness of person and surroundings of patient, failure of subjective cleanliness, use of improper lubricants, courting fever by frequent and unnecessary interval examinations, C. S. BACON cautions midwives against "finding it much easier to put up with their surroundings than to improve them" and advises them to be very particular even to faddism or fussiness of the most minute details of cleanliness but on no account to usurp the province of the physician. It is the midwives' duty, he urges to insist on the expecting mother keeping a piece of white oilcloth 4.5 feet square, thoroughly boiled and washed, 6 clean sheets together with absolutely clean linen for pads, receivers and the like ready against her confinement. When labour begins remove all the bedclothes, cover the mattress with the oilcloth and a clean sheet only, and make the patient be on it after she has had a bath and an enema and put on a clean night dress. Before each interval examination wash the external genitals thoroughly with soap and disinfect the hands carefully by scrubbing first with hot water and soap, and then with 1 per 1000 sublimate or 1 per cent. lysol or 3 per cent carbolic acid solution. Do not give a vaginal douche before, during or after labour. When the afterbirth comes away remove sheets and pads, wash patient and oilcloth with antiseptic solution, dry both and over the latter spread a clean sheet for the former to lie on. For napkins use perfectly clean cloths, change napkins, sheets and pads as often as necessary but each time wash the patient with soap and warm water.—*Jour. Amer. Med. Assoc.*

Placenta Prævia.

If hemorrhage be (1) slight (2) moderate or (3) profuse (a) before labor D. W. H. WENNING recommends (1) rest, expectant treatment, (2) vaginal tampon or (3) tamponing and induction of labor; but if it be moderate in the (b) beginning of labor BRAXTON HICK's tamponing cervix with the cervical pad is useful, till (c) labor is well in progress when rupture membranes and deliver (1) by pedicle version or (2) by forceps, if hemorrhage is arrested by the descending hand or (3) by spontaneous expulsion if the

pains are good. If the hemorrhage is excessive at any stage and cannot otherwise be arrested, manual dilatation followed by forcible delivery should be effected.

The tampon is indicated (1) in hemorrhage towards end of pregnancy or in the beginning of labor when (2) the os is closed or (3) the cervix is moderately dilated; but not when (1) dilatation is complete or nearly so nor when (2) it fails to arrest bleeding at any stage of dilatation.

Rupture the membranes when the os is well dilated and (1) spontaneous or artificial delivery will occur or (2) in the absence of "pains" the presenting part will immediately cause pressure and (3) any of these three will control the hemorrhage; but do not rupture the membranes if (1) the os is undilated and the pains are good or (2) in faulty presentation of the foetus.

Version by (1) BRAXTON HICK's method or (2) direct or internal or (3) followed by forcible delivery is indicated when (1) the os will admit two fingers or (2) when it is well dilated or dilatable and hemorrhage is profuse or (3) in desperate cases; but it is contra-indicated when (1) it cannot be skillfully made with a moderately dilated os or (2) when with a well-dilated os after rupture of the membranes the head immediately engages in the cervix.—*N. Y. Med. Rev.*

External Exploration in Obstetrics.

It is argued by some that irregular and painful uterine contractions, detachment of the placenta and changes in the attitude of the foetus may be caused by external manipulation of the abdomen in pregnancy, but LEOPOLD in whose clinic over 1000 cases were treated declares he never observed any ill effects in any of his cases and always found it possible to manage normal labor with the sole use of external exploration which readily enables him to determine (1) the direction of the long axis of the infant (2) the position of its back and limbs and (3) what fetal part occupies the fundus uteri, as well as to a certain extent (4) the presenting part and (5) to what extent it engaged in the pelvis. He urges that it is the obstetrician's duty to refrain as far as possible from vaginal examination in normal cases; because (1) internal examination is useless when external exploration gives all the needed information and (2) a woman during labor may readily be infected by her medical attendant (3) whose hands should always be considered septic since (4) they cannot be made germ proof by rapid disinfection.—*Med. Chron.*

Hysterectomy for Acute Puerperal Septic Metritis.

MENEBERG reports a successful case. Symptoms began on the sixth day after confinement; three days after curetting was done, and was followed by improvement for twenty-four hours. On the twelfth day the patient was taken to hospital, apathetic, delirious, with temperature 103, and pulse 180. Intra-uterine irrigations brought away no debris. On the evening of the thirteenth day she seemed sinking, and abdominal total hysterectomy was done. On cutting open the uterus the whole interior above the cervical canal was covered with a dark, tenacious, almy discharge, emitting a very foul odour. Attached to the left horn was a piece of placenta 2 cm. by 4 cm. and firmly adherent. The patient left hospital in six weeks. The author explains the lateness of the onset in these cases as follows: A piece of retained placenta disintegrates, and the debris are at first carried away with the lochia. After a week the cervical canal becomes moderately closed, and at the same time the heavy fundus sinks forward so that escape of the discharges is interfered with, resulting in absorption and sepsis. This may occur without factor of the lochia. The proper treatment is immediate curetting, followed by special precautions to allow of subsequent drainage. If this fails, as shown by rapid weak pulse and loss of ground by the patient, hysterectomy should be done. In a footnote to the paper the author reports a second and later case, where the same treatment was successfully carried out. He gives references to eight other cases reported.—*B.M.J.*

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

Abnormal Ureters.

JOHN H. MORGAN Esq. M.A., F.R.C.S.I. thinks that aberrations from the normal type of ureters are of special interest with regard to their causative relations to congenital hydronephrosis, as out of 53 such cases recorded by Sir W. ROBERTS 20 had congenital malformations.—4 had imperforate ureters, in 3 the ureter entered the pelvis of the kidney too obliquely, in 2 a supernumerary renal artery crossed and compressed the ureter near its origin, in 1 (Dr. HARR's patient who lived to the age of 38) both ureters were coiled on themselves near this origin and adhered to the lower part of the dilated pelvis, 4 lived for ages varying from $\frac{1}{2}$ to 30 years and the remainder died very young. SWART (*Lancet*) tells of a case where each kidney had two previous ureters arising from distinct pelvis and terminating independently in the bladder, and in the museum of the Charing-cross Hospital is a case where the second ureter arising from the pelvis a good deal higher than the other one which begins at the usual situation, runs nearly a straight course downwards to a point 5 inches above the bladder where it joins the proper duct at right angles, and in the great Ormond Street Childrens' Hospital were 5 more cases of double ureter; but in no case were they the source of disease.

In a case of cystic kidney removed by Dr. DAY an imperforate fibrous cord terminating in the bladder represented the ureter and caused dilatation of the kidney. In another case born with renal cystitis (*Trans. Path. Soc. of Lond.*) the right ureter was doubled to within 0.5 inch of its lower end, a valvular fold of mucous membrane marked the left one, the anus was imperforate and the bowel transposed, and in a third case the ureter was short narrow, patent, and its orifice, no larger than a pin's head, placed inferiorly.

SHATTUCK (*Trans. Lond. Path. Soc.*) looks upon double and treble ureter as reversion to a lower type as in the amphibia which have as many ureters as there are segments of the kidney, of which that portion connected with the superior of the ureters represents a persistent segment of the mesonephros whose duct has remained functional and supplementary to the permanent kidney with which it retains its primitive continuity.—*Trans. Lond. Med. Soc.*

Digestion of Children.

In his Report on the Pathology of Infantile marasmus Dr. FENWICK notes:—(1). The acidity of the gastric contents steadily increasing during the progress of digestion attains its maximum of 0.185 per cent.—calculated as hydrochloric acid—within 90 minutes from the commencement of the meal; but (2) the quantity of the mineral acid secreted during digestion varies from day to day and from meal to meal in the same child even though the same quantity and quality of food be taken at each meal, and (3) so long as the gastric secretion contains a trace of hydrochloric acid pepsine and rennet are invariably present, whereas (4) the appearance of lactic and other secondary acids which are not normal products of digestion, denote fermentation and (5) the total acidity of the gastric contents in infants fed on farinaeous food, invariably diminishes to below the normal

(6). Free hydrochloric acid is never found in the stomach till 90 minutes from the commencement of a meal, though (7) it is always present towards the latter end of digestion.

(8). In breast-fed children the milk-curdles in 8 to 15 minutes after it reaches the stomach and (9) gastric digestion is usually completed in 90 minutes when the stomach is

void of food; but (10) in children fed upon sow's milk, the total acidity exceeds that of breast-fed babies by 0.18 to 0.195 per cent and (11) the stomach becomes empty in 135 minutes, when digestion ends.—*Brit. Med. Jour.*

Biomechanics of the Circulation.

TRYING the advisability of a "Multiple pulse-feeling" in preference to "taking the pulse" at one vessel only, Professor BENEDICT of Vienna thinks that always working under normal circumstances, with a portion only of the power it is capable of exerting the heart always has at hand surplus energy for an emergency such as valvular insufficiency, when it compels the vascular system to help it by local dilatations which relieve the central organ, until by a reflex action through the nervous system a compensatory hypertrophy is established to meet the strain of the increased work. He notes that the heart sounds are due neither to valvular tension nor to muscular contraction but to vibration in the blood in the ventricular cavity during the period between the closure of the mitral cusps and the opening of the semilunar valves, and in the attractions and repulsions of cellular action throughout the body he sees the generation and utilization of a force, stored by the nervous system, for the regulation of the body locally and generally by compensatory dilatations, that so relieve the contracted blood vessels that sinapism is superior to ice in cerebral congestion.—*Loc. Prag. Med.*

Tuberculosis of the Kidney.

CHRONIC localised tuberculosis or strumous disease of the kidney is by no means frequent in children but the acute miliary form, which is only a local manifestation of a general disease is in children, very commonly associated with tuberculous or meningitis. When the disease originates, in the urinary organs the infection may be conveyed by the blood, or it may ascend from the bladder by the ureters or lymphatics or it may extend from the surroundings of the kidney, whose invasion is seldom marked by any distinct symptoms and the kidney affection may further be disguised by the more evident signs of disease in the lungs or in the brain. Such conditions do not admit of surgical interference. Carried along by the blood for elimination by the glomeruli, the bacilli infect the apices of the papillae, the calyces or the pelvis of the kidney which become the camping ground for miliary nodules, which coalesce to form caseous masses that break down to form irregular cavities in the periphery or lay bare ulcerating surfaces in the pelvis. The infection becoming more chronic, more and more renal substance becomes involved, destroying the serous structure, ulcerating the mucous membrane occluding the lumen and thickening the ureter, which last may remain pervious to wash away the debris to involve the parts below and let the disease ascend to the opposite kidney; but if the ureter becomes blocked tuberculous pyonephrosis may result, converting the kidney into a large abscess cavity or a number of cavities filled with caseous debris or the whole organ may become a shrunken putty-like mass.

In the earlier stages nephrotomy may be advantageously employed and later on if patients' strength improves or lardaceous disease threatens nephrectomy may successfully be resorted to with a not very high mortality if the disease is unilateral; but when the urine becomes constantly purulent and vesical irritation is a marked characteristic the disease has either implicated both kidneys or so far involved other portions of the tract that permanent cure is impossible and only palliative measures may relieve the patient temporarily.—*Lancet.*

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Evils of Excessive meat eating.

As soon as man subverts his stomach that organ demands an excess of meat followed by an excess of stimulants all of which combine to force a lot of extra work on the system, leading to a long train of evils which may be overcome by adopting a strictly vegetable diet, and the *New York Medical Times* thinks that the great increase in the cancer mortality in England is in a very large part due to the excessive ingestion of meat by persons whose cellular metabolism being defective, the extra work thrown on it stimulates the system to such an extent as to create such excessive and disorderly cellular proliferation as will eventually in cancer.

Mrs. MANNET HART says that urbanity is the rule in less-meat-eating France and an exquisite politeness prevails in fish and rice eating Japan where she never heard rude or angry words spoken by any but Englishmen. She is very strongly of opinion that the proverbial ill temper of the English is caused in a great measure by too abundant meat dietary combined with a sedentary life and the half oxidised products of albumen from muriates and muric acid circulate in the blood to produce physical, mental and moral disturbances such as dyspepsia, gastric disorders, cancers, irritability, aggressiveness, selfishness and a frequent desire to become quarrelsome.—*N. Y. Med. Times*.

Decision Favorable to a Contagious Disease Hospital.

IN a suit to prevent the maintenance of a small-pox hospital on the ground that it is a nuisance to the neighbouring residents of the small Yorkshire town in which it is situated, Justice ROMER sitting as an equity judge, lately heard considerable interesting medical testimony in regard to the manner in which small-pox may be conveyed from the patients in such an institution. The complainant's witnesses were generally of the opinion that the diseases could be transmitted through the air to some extent, outside the precincts of the hospital. One witness, however, the government health officer at Hastings, limited the likelihood of outsiders being reached by small-pox to such persons as came within 600 feet. This theory of aerial convection, as it is called, was rejected by the medical men testifying in defense of that Yorkshire hospital, which expressed great confidence that whenever all the facts of a case of small-pox could be ascertained it would appear that the malady was due either to direct or mediate contagion, that is, contact with the patient himself or with a person who had seen the patient. Justice ROMER refused to adjudge the hospital to be a nuisance, but did not expressly determine whether the theory of aerial convection is or is not correct.—*J. A. M. A.*

Disinfection of Excreta.

DRS. C. A. HILL and J. H. ABRAM have made a series of experiments to ascertain the value of various well-known substances used for this purpose. Typhoid stool was made use of, and was exposed to the action of the agent for half an hour in each case. The results of their experiments are summed up as follows:—

1. It is absolutely necessary to mix the faeces thoroughly with the disinfectant.
2. The mixture should stand at least half an hour.
3. Carbolic acid (1 in 20), crude carbolic acid (1 in 40), formal (1 in 40), creolin (1 in 40), chinocol (1 in 600), and corrosive sublimate (1 in 500), are all effective, but chinocol seems the most convenient.

The reasons for coming to this conclusion are that corrosive sublimate is a scheduled poison, acts upon the meta-

work of the drainage system, and, moreover, gives a red coloration with stercobilin. This latter point is of importance, inasmuch as it may mask the presence of blood in a typhoid stool; again, albumen is coagulated by mercuric chloride, and thereby protects organisms enclosed in the centre of the coagulum. Crude carbolic acid is cheap and efficient and but does not mix well with the faeces, it stains linen, and is poisonous. Formal and creolin are good, but are rather costly. The remaining substance, chinocol, is, in their opinion, the best. It is reliable, an excellent deodorant, and mixes well with the faeces. It is dearer than crude carbolic, but its cost is more than counterbalanced by its portability. It is put on the market in tablet form. The tablets are readily soluble, and may be obtained in such strength that one of them in a pint of water makes a solution of effective strength.—*Brit. Med. Jour.*

Extraordinary Deaths.

IN BIRMINGHAM, on 11th May, an inquest was held at Dudley on the body of a woman aged sixty-five years, who met with her death in an exceptional manner. After kneeling at the grave of her brother in the cemetery she made an effort to rise, but in doing so, fell into the vault over which she was kneeling and disappeared from view; when taken out she was dead. Her weight was 16 st. 12 lb, the vault was from 8 to 9 ft. deep. On 4th May, an inquest was held on the body of a woman, aged thirty-three years, the subject of delusions. The deceased was found on the floor of the house dead, her clothing saturated with water, and a pool of water around. There was nothing found to account for her condition. The canal was a quarter of a mile away. The medical man who made the post-mortem examination, said, that he came to the conclusion that the deceased had died from asphyxia caused by water—practically drowning. He added that according to an American authority a case was recorded where a person who had been immersed in water had recovered sufficiently to walk a considerable distance and had then died. From the condition of the deceased's body and clothing he thought that she had been completely immersed in water. The jury found that death was due to drowning but that there was no evidence to show how the drowning was caused—a conclusion which must be viewed as exceptional in the history of deaths from drowning.—*Lancet*.

Simple Test for the Purity of Water.

THE *Massachusetts Medical Journal* for May quotes from *Health*, for persons who cannot command chemical analysis, the following simple tests for the purity of water:

Fill a bottle made of colorless glass with the water; look through the water at some black object; the water should then appear perfectly colorless and free from suspended matter. A muddy or turbid appearance would indicate the presence of soluble organic matter, or of soluble matter in suspension. It should be "clear as crystal."

Empty out some of the water, leaving the bottle half full; cork up the bottle and place it for a few hours in a warm place; shake up the water, remove the cork, and critically smell the air contained in the bottle. If it has any smell, and especially if the odor is in the least repulsive, the water should be rejected for domestic use. By heating the water to boiling, an odor is sometimes evolved that otherwise would not appear.

Pure water should be tasteless and remain so after being warmed. It should also be odorless; but, since the delicacy of smell and taste varies greatly, sanitarians attach special importance to HENSON'S test for sewage contamination or the presence of putrescible organic matter. A clean pint bottle is filled three fourths full of the water to be tested, and in the water is dissolved a teaspoonful of the purest sugar—loaf or granulated sugar will answer; the bottle is then corked and kept in a warm place for two days. If in from twenty-four to forty-eight hours the water becomes cloudy or muddy, it is unfit for domestic use. If it remains perfectly clear it is probably safe to use.

THERAPEUTICS AND PHARMACOLOGY.**Oxygen in Opium Poisoning.**

THIS gas, which plays so important a part in the daily action of life and has been successfully employed in coal gas asphyxia and dyspnoea and cardiac failure from many acute diseases, was recently used by Dr. W. J. C. MURRAY in a case where a man had swallowed 3 ounces of chlorodyne (containing 8 grains of morphia, corresponding to nearly 100 grains of *Smyrna opium*) some three hours before the police discovered him, lying insensible on the ALBERT EMBANKMENT and brought him St. THOMAS'S Hospital. He was cyanosed, breathing stertorously, corneal reflex abolished, pupils contracted and inactive, pulse rapid and weak, limbs flaccid and enforced exertion being out of the question the interrupted current, flagellation, cold affusion and strong ammonia to the nostrils were successively tried with rather indifferent response for 3 hours, but the moment the battery was discontinued he relapsed into profound coma and his condition becoming more and more serious (his respiration fell to 8 per minute, face became intensely blue and lips and fingers livid) he was made to inhale pure undiluted oxygen gas for 20 minutes, when respiration became fuller, easier and quieter while his face regained a nearly normal color and his pulse picking up beat regularly 100 to the minute. A second inhalation of 20 minutes, given an hour later restored consciousness and two more 20-minute inhalations at 45 minute intervals completely revived the patient. That the oxygen was the turning point in the case is beyond doubt but without further experience of its use in similar cases it would be difficult to understand its exact mode of action.—*Lancet*.

Hydrocyanic acid as a Antidote to Chloroform.

THE idea of using prussic acid as an antidote to chloroform first suggested itself to FREDERICK HODDAY EYRE, F.R.C.V.S., some two years back, since when he made a number of experiments whose results were in the highest degree satisfactory, so much so that when chloroforming animals, the only antidotes he keeps ready to hand are hydrocyanic acid and liquor ammoniæ fortior. As soon as breathing ceases or becomes dangerous, artificial respiration is resorted to; the tongue being continuously pulled well forward in a jerky manner and a full medicinal dose of SCHEELE'S acid which is a powerful respiratory stimulant, placed as rapidly as possible at the back of the throat. When respiration has re-commenced the ammonia vapor is applied cautiously to the nostrils and in the majority of cases a safe termination ensues. SCHEELE'S acid is more rapid and powerful than the British Pharmacopœia and acts best when given undiluted.—*Lancet*.

Kryofin in Influenza.

BRESLER who tried this methylglycolic acid compound of paraphenetidin in 16 cases of influenza, found that this drug was more speedily and completely acted upon by the both the pancreatic and gastric juice than was phenacetin, and that if 75 grains of kryofin were given just before a rise of temperature was expected, the pyrexia was a rule forestalled as this drug which improves the subjective condition considerably and often induces diaphoresis, had the peculiarity of preventing a rise of temperature rather than of bringing it down, and was certainly preferable to phenacetin or antipyrin as an antipyretic and anti-influenzal remedy.—*Therap. Monats.*

Magnesium Sulphate in Tropical Dysentery.

V. GANSON THOMAS while in charge of H. M's gunboat *Peacock* then lying in the Yangtze River, Obien, gave

3j. of a saturated solution of Epsom salts and Acid sulph. dil. m̃x. every hour, to a severe case of dysentery with such striking and immediate effects and no complications that he declares, that in any future case of dysentery he may have to deal with he intends giving Magnesium Sulphate in preference to Ipecacuanha. Dr. THOMAS E. WIGLESWORTH, who keeps his patient on milk diet and gives him "acid sulph. Dil m̃xv. Sat. sol. magn. sulph. 3iv." every two hours endorses these findings with "I feel certain, if the magnesium sulphate treatment were carried out that in the majority of cases tropical dysentery would be shorn of half its terrors."—*British Med Jour.*

Guttaud's Amenorrhœa Pills.

R Strychnine sulphate ... ½ grain;
Iron peptonate,
Manganese lactate, } each ... 20 grains.
Scammony,

Divide into forty pills. Two to four pills to be taken every night on going to bed.—*N. Y. Med. Jour.*

Spasmodic Cough.

Potassium bromid ... 1 dram.
Wine of ipecac ... 1½ fluidrams.
Tincture of belladonna ... 1½ fluidrams.
Syrup of tolu ... 6 fluidrams.
Water ... 4 fluidounces.

Dose: One to two teaspoonfuls every three hours.—*Med. Review of Reviews.*

Irritative Dyspepsia.

Bismuth subnitrate ... 2 drams.
Magnesium carbonate ... 2 drams.
Dilute hydrocyanic acid ... 35 minims.
Tincture of hyoscyamus ... 6 fluidrams.
Mucilage of acacia ... 1½ fluidounces.
Peppermint-water ... 6 fluidounces.

Dose.—One tablespoonful in water after meals.—*Med. Review of Reviews.*

Discoloured Teeth.

THE following is a dentifrice recommended in *L'Odontologie* for the use of persons the enamel of whose teeth has become discoloured:—

R Chlorate of Potash ... gr. lss.
Powdered Boracic Acid ... gr. liij.
Carb. of Magnesia (heavy) ... gr. liij.
Precipitated Chalk ... gr. liij.
Ess. of Peppermint ... grt. v.

Pract.

Vomiting of Sea-sickness.

Menthol ... 1.5 grains.
Cocain hydrochlorate ... 3 grains.
Syrup ... 1 fluidounce.
Alcohol ... 2 fluidounces.

Dose.—One teaspoonful every half hour.—*Bulletin Med.*

Indigestion, Heartburn, and Nausea Powder.

THIS is composed as follows:—

Mag. calc. levis ... 3j.
P. calumbæ ... 3m.
P. singh. ... 3ij.
P. glycyrrh. decort. ... 3j.

M.

One teaspoonful for a dose.

Correspondence.

THE C. D. ACTS IN INDIA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—In your issue of 1st May, "A Medical Man" is very severe on the "ridiculous" Memorial of 79 Medical Women, concerning measures for dealing with venereal disease. As one of the 79, will you kindly allow me space for a reply?

The portion of the memorial which specially arouses the wrath of your correspondent, is that which gives reasons why it is, in our opinion, "impossible to class venereal diseases, with other infectious and contagious diseases, for purposes either of prophylaxis, segregation or treatment." We say "Other contagious diseases are, as a rule, easily recognized, rarely or with difficulty concealed, treatment is voluntarily sought These things are not true in the same degree of venereal disease." As your correspondent seems to think that these differences exist only in our ignorant unaginations, I should like to quote the following from Lord LISTER's speech in the House of Lords on the proposed Cantonment Regulations (17th May, 1897).

"Now with regard to such diseases as small-pox, this regulation is, of course, perfectly satisfactory . . . But with venereal disease the case is totally different. In the early stages of the complaint, in which it is of the most essential consequence that it should be recognized—for efficient treatment depends upon early recognition—there is no general effect whatsoever produced upon the system. The person appears to all ordinary examinations perfectly healthy, and it is only by special examination, which it is enacted shall not be compulsory that evidence of the disease can be obtained. How can any notice be given to the medical man that a person has such a disease? Who is to give the notice? In truth it is the fact of prostitution, not evidence of the presence of venereal disease, on which the authorities must proceed."

Under the present regulations, it is open to a medical officer to take the fact of prostitution as "*prima facie* evidence" of the existence of disease and to proceed accordingly. But since prostitutes can only constitute a proportion and usually a small minority of the total number of sufferers from venereal disease in any community,—it is evident that, as regards the initial step of detection, these diseases are on a very different footing from those others with which it is attempted to class them.

Putting aside for the moment this very serious difficulty, it is clear that if we are to deal with syphilis on the same principles as other communicable diseases, we must endeavour to secure:—

1. That every case, whether in man, woman, or child shall be compulsorily notified.

2. That every case shall be efficiently isolated (or segregated) throughout the period during which the disease is transmissible: *i.e.*, for two years at least [I take two years because that is the minimum interval before marriage is allowed. Even if we are not prepared to subscribe to the modern view that during the latent periods of the secondary stage, the blood and some of the secretion contain and may transmit the syphilitic virus, it is certain that the active manifestations are capable of communicating the disease, and may do so, before they become sufficiently troublesome to call for treatment—or even, in the interval between two examinations.]

A serious objection to such proposals would be that they would throw much practice into the hands of quacks who could be trusted not to certify; but if concealment of disease were visited with sufficiently heavy penalties it is possible that in a few years, cases of syphilis would be less numerous. But where is an administration bold enough to enact and impartially, enforce such measures,

and strong enough to resist the opposition of tax-payers on the one hand, and of those whose liberty would be interfered with, on the other?

In the meantime, I maintain that measures devised for dealing with small-pox and cholera are inapplicable to syphilis. The pretence of similar treatment can only mean that a proportion of the cases are segregated during a part of their illness; and if this pretence leads the public to suppose that they may neglect the ordinary means of safety, it will inevitably defeat its own end.

A Medical Man's remarks about "the trade of prostitution" indicate that what he approves and what he hopes the Cantonment Rules will lead to, is a revival of the system known in England as the contagious Diseases Acts, and on the continent of Europe as "Reglementation" and he assumes as do most of those who have not studied this hateful subject, that that system *does* check venereal diseases if it cannot stamp them out. He quotes Dr. COMMANGE's statement that syphilis is rarely engendered by regulated, and nearly always by clandestine prostitution. It is interesting to put this statement beside the testimony of M. LECOUR, for many years head of the Police des Mœurs in Paris; on one page he says "Prostitution is increasing and becoming more dangerous to the public health,"—now the next "The administration has redoubled its activity . . . and it has finally succeeded in maintaining the registered public women in a satisfactory sanitary condition. The explanation is furnished by his figures, which show that in spite of (or perhaps rather in consequence of) his efforts, the clandestine prostitutes are seven times as numerous as the registered. (Lecour, *La Prostitution à Paris et à Londres*, pp. 254, 255, 120, and 127. This book was published in 1874, but there is no reason to think the state of things in Paris is any better to-day.)

When a Medical Man deals with our remarks as the treatment of soldiers, he becomes too indignant to be civil,—but he does not enlighten our ignorance. The question is simply this: when a soldier has shown symptoms of secondary syphilis, is he subjected to systematic mercurial treatment for two or three years? If not, can he be said to be "properly treated," according to the general consensus of medical opinion? We did not attempt to question the excellence of the soldier's treatment while in hospital. We only say that if he cannot have "out-patient" treatment between-while it is to his disadvantage and to that of the State, and it is no wonder that the disease sometimes assumes a virulent type.

In this letter I have confined myself strictly to the medical aspect of the subject. It is only on that aspect that your correspondent attempts to argue. The moral question he treats with cheap sneers, which need no reply.

Yours &c., X. Y. Z.

MEDICAL EDUCATION IN THE PUNJAB.

TO THE EDITOR, "INDIAN MEDICAL RECORD"

SIR,—I send you herewith per book post the Punjab University M. B. and L. M. B. Examination papers for 1898, for publication in the *Record*. The students' corner in the columns of the *Record* which was talked of some time ago, have been ever since neglected and none have come forward to contribute anything intended to be especially useful for the students preparing for the University examinations.

As far as my experience of the Lahore Medical College goes, the *Record* is the only medical paper subscribed for by the students and largely read by them, and if the students of the other Indian Colleges have an equal predilection for it, it shows that it is read by not a small minority of them. If a page or two be devoted to their cases and specialized for their use they will feel still more attached to their beloved journal.

Even when I was a student, I occasionally wrote clinical reports for the *Record* which were approved and published, and now as my student career is at an end, I hope to try and do my duty towards these columns.

Every page of the *Record* has something new to tell or teach any student of medicine, but to fulfil the requirements of the candidates for Indian Universities, a page or two should be set apart in which they or their teachers may be able to discuss University and other important questions, connected with every branch of the medical service.

The following is the list of the successful candidates in the M. B. and L. M. S. of the Punjab University Examinations which were held on 30th June last, the results were out on the 30th ultimo.

SECOND M. B.		Total marks. 1850.
Amrik Singh	807
Barj Nath Veyas	677
Jai Chandra	808
L. M. S.		
Gurdial Singh	791
Angbar Ali	730
Gopal Dass	749
Duni Chand	680
Ram Chad	748
Har Parabad	698
Kidar Nath	691
Shanker Dass Khanna	691
Kanonji Lal	724
Balbhadra Singh	767
Chaman Lal	683
Surrendra Nath Banerji	739
Vinjak Ludaahive	726

The candidates for the L. M. S. were 34 in all, for the M. B. only 3, of whom all passed.

Yours &c., AMRIK SINGH, M.B.,
Assistant Surgeon, Nabha State.

NABHA STATE, 4th August 1898.

THE ADMINISTRATION OF THE INDIAN MEDICAL DEPARTMENT BY CIVIL SERVICE SECRETARIATS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—While, for the honor of the Medical Services of India and of the Medical profession, I would fain see the supreme power in all matters of medical administration in the hands of medical men, I cannot refrain from wishing most fervently as things stand at present, with the affairs of the medical services and of the medical profession in this country so absolutely at the mercy of the civil secretariats, that the useless expense of paying huge salaries to figure-heads of medical administration, as a criminal waste of money and that such appointments be abolished. Why should we pay Rs. 2,500 monthly to Inspector-Generals of Civil Hospitals, when they do almost next to nothing for such an honorarium, when the secretary to the Government on the "Medical and Municipal" departments orders everything in medical affairs according to his whims and caprices, and the L.G. says yes, good, bad or indifferent in all that is done.

That man of signed professional experience and with a dignified position should submit to being treated as merely nominal heads, as automata, as figure-heads, unworthy of the smallest consideration, as beneath consultation, beats all my conceptions of madness, and therefore I beg to propose that all Inspector-Generals of Civil Hospitals and even the Director General of the

Indian Medical Service (with the exception of another showman), be entirely and for ever abolished, and that the civil servants who now do all the work of medical administration in India, even to the writing of scientific theses on plague and other diseases, be invested with public power to openly, instead of secretly, administer the medical services and the medical needs of the country. Let us try Bengal as an experiment, and to bolster up this proposition, I would ask some one else who knows a thing or two as I do, to just publish in the *Record* a statement of the daily routine of work done by the Inspector-General of Civil Hospitals of Bengal. This done and my proposition will be approved of on all sides.

Yours &c., ECONOMY.

SCANDAL MONGERS IN THE PROFESSION.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I was very pleased to read your scathing criticism on the unprofessional conduct of a Surgeon of the Indian Medical Service who slandered a non-official brother. Your sermon on scandal-mongering was to the point, but besides "words" used for the purpose of injuring the reputation and position of non-officials, it is well to recognise the fact that there are some official doctors in our public hospitals, who while they do not dare to speak ill of their non-official brethren, and thus lay themselves open to legal action, they are guilty of equally as unprofessional and far more insidiously mean and cruel conduct, when knowing the prestige and status they hold in a public hospital, they sneer and jeer and shrug their shoulders, when the name of a non-official physician is mentioned as the man in charge of the patient before he or she went to hospital. Dishonorable to the core as two or three such heartless members of the Indian Medical Service in our public hospitals are, it is only right and honest to say, that no such reflection can be cast on the majority of the official doctors, who besides, honorably and generously recognising the difficulties of the non-official practitioner, and treating him as a professional brother, they support him with a recommendation and a good word. Such men would not dare to stab a man in the dark, nor strike him "under the belt."

Yours &c., S. O. M.

CALCUTTA, 12th August 1898.

ANOMALOUS MEDICAL PENSIONS.

TO THE EDITOR, "INDIAN MEDICAL RECORD"

SIR,—Some short time ago the *Pioneer* advertised on an "Anomalous state of pensions," now it so happens this "Anomaly" only concerned the Indian Subordinate Medical Department. Yet in vain have I watched for any agitation to keep the "ball rolling once set in motion" as alluded to above. Your championship of the Anglo-Indian is very up hill work if none of the class take up the matter so successfully led for them. The Statesman is recorded to have said "This new Indian Congress movement will have to reckon with." Is the Anglo-Indian sunk to such apathy, that the Bengali Baboo can beat him at vigorous, united, and continued action, commonly styled agitation.

Things look bad indeed if such is the case. How many Anglo-Indians on your books have struffed for the Indian Medical Association, and how many more have neglected to send in their subscriptions? How many have never joined? It is this apathetic happy-go-lucky style that prevents any interest being taken for a substantial fund, as for instance the "anomaly" herein written of in no way is detrimental to the British born "superior" imported articles, but to the domestic only.

Yours &c., ISAKI GOWAN KATTANAKK,
Army Physician, late 55th Regiment of Foot.

WHO ARE THE WARRANT OFFICERS AND MEN OF AN INDIAN ARMY MEDICAL CORPS?

To THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I was pleased to read in the Record a short while ago that the Government of India had under consideration the petition submitted by the I. M. Association on behalf of military assistant surgeons. As the matter has, evidently, not yet been disposed of, and further as I am given to understand that a bigger subject is also before Government, consequent on the new Warrant re Royal Army Medical Corps, would it not be advisable for the Association to again approach Government at this important juncture? In addition to what has already been advocated by the Association as regards the pay, pensions, and prospects of this hard-worked class of public servants I would, to keep up with the times, beg to suggest the following for favourable consideration:—

(1). That the designation "Indian Subordinate Medical Department" be changed to Indian Military Medical Establishment or Department, synchronous with Military Works Department, Army Commissariat and Ordnance Departments, &c., a designation which would also serve to distinguish it from the Civil Medical Department.

(2). That the members of the department be designated, Deputy Commissaries, Assistant Commissaries, Deputy Assistant Commissaries, Conductor, and sub-Conductors.

At present they are supposed to hold a sort of imaginary relative rank with the members of the sister services which is considered unsatisfactory. It is moreover obvious that if the term Surgeon is to be abolished in the Commissioned Medical Services, the designation Assistant Surgeon becomes meaningless and must be expunged.

Yours &c., P.

—:—

THE PRESIDENCY GENERAL HOSPITAL.

To THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—May I ask whether the Presidency General Hospital of Calcutta, which was roundly condemned by the public during the incumbency of Surgeon-Colonel CROMBIE and the staff then employed under him, is to be re-organized and placed under new management? Surely if it failed to give public satisfaction under Dr. CROMBIE, it can hardly be predicted to render efficient service when placed in charge of Dr. CROMBIE's second in command!

If the management was faulty, and it admittedly was very faulty, there should be a clean sweep of the whole staff. To do otherwise is to act imprudently, blindly and blameably. How can a pupil do other than follow in the footsteps of his master. If CROMBIE failed, and fail he did, with the management of the Presidency General Hospital, how can his assistant succeed? He will work on the old grooves and the results will be as discouraging and as blameworthy as before.

Yours &c., W. C.

—:—

WANTED TREATMENT AND OPINION.

To THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—What is the best treatment to adopt in cases of styas. These are very painful when they appear and any treatment both external (as a lotion) and internal which has been found effective will oblige the writer. Wanted a treatment so as to prevent a recurrence of these boils.

What is the best treatment to follow in cases of acute coryza. I have never up to now found any thing which can really cure the symptoms of a severe cold. The inhalation of oil of eucalyptus is the treatment recommended but I do not place implicit faith in this.

Yours &c., MEDICUS.

BOMBAY, 19th July 1898.

ASSISTANT SURGEON MONTGOMERY'S CASE.

To THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I was both surprised and annoyed at seeing a letter in the Indian Medical Record, of 16th July 1898, under the heading "Fair play for the I.S.M.D.," and signed "Fair Play." I beg you to insert in your most valued and esteemed paper, the Indian Medical Record, my denial of its authorship and my regret at its appearance. I am in total ignorance of its authorship.

Yours &c., PIERRE MONTGOMERY.

FATEHGARH, 30th July 1898.

Government Medical Gazettes.

GOVERNMENT OF INDIA.

Surgn.-Col. D. O'C. Rave, M.D., I.M.S. (Bengal). Inspy.-Genl of Civil Hospis, Punjab, is granted furlough out of India on private affairs, for eight months, from 10th Aug. 1898.

The services of Surgn.-Major E. F. H. Dobson, M.S., I.M.S. (Bengal), are replaced temply. at the disposal of the Milly. Dept.

The services of Surgn.-Lieut. H. J. Walton, M.S., F.W.S.S., I.M.S. (Bengal), are replaced at the disposal of the Milly. Dept., from 6th July 1898.

The services of Surgn.-Capt. A. G. Hendley, I.M.S. (Bengal) are replaced at the disposal of the Chief Commr., C.P.

BENGAL GOVERNMENT.

Babu Ambica Charan Dutta, a passed student of the Med. Coll., Calcutta, is admitted into the service of Govt., as an Asst. Surgn., from 23rd June 1898.

Brig.-Surgn.-Lt.-Col. O. H. Joubert, Professor of Midwifery, Med. Coll. Calcutta, and Obstetric Physician, Eden Hosp., is allowed privilege leave for one month and twenty-two days.

Surgn.-Capt. O. R. Stevens, Resident Med. Officer, Med. Coll. Hosp., Calcutta, to act as Prof. of Midwifery, Med. Coll. Calcutta, and Obst. Physician, Eden Hosp., during the absence of Brig.-Surgn.-Lt.-Col. O. H. Joubert.

Brig.-Surgn.-Col. W. H. Gregg, Civil Surgn., of Bardwan, is granted furlough out of India for twelve months.

Surgn.-Major A. B. W. Sedgefield has been granted a further extension of furlough for two months.

Asst. Surgn. P. Victor, to be an Inspy. Officer for the purpose of carrying out the provisions of the Epidemic Diseases Act, 1897, at Chakradharpur on the B. N. Ry.

Surgn.-Lt.-Col. E. Bovill, Offg. Civil Surgn. of Howrah, is allowed privilege leave for three months, from 29th July 1898.

Surgn.-Capt. C. R. M. Green to act as Civil Surgn. of Howrah.

Asst. Surgn. Kali Mohun Sen, to do superny. duty at the Med. Coll. Hosp., Calcutta, from 28th July 1898.

Asst. Surgn. Mohendra Nath Dutt, a superny. at the Med. Coll. Hosp., to have tempy. charge of the Kumbharpur Disp.

Asst. Surgn. Ghosh Bhanu Singh, of the Munshampur disty., leave for three months.

PUNJAB GOVERNMENT.

Asst. Surgn. Mehr Chand, Med. Officer, Baghewali Section, Southern Punjab Ry., was transferred in a similar capacity to the Jind Section of that Ry., from 20th June 1898.

Hosp. Asst. Uttam Chand Gujranwala, to Karanwalla Disp., Garat Dist., from 18th July 1898.

Hosp. Asst. Uttam Chand and Mohammad Azeem, Acting genl. duty Mayo Hosp., Lahore, to Gujranwala in a similar capacity, from 6th and 7th June 1898.

Hosp. Asst. Uttam Chand, Gujranwala, to Dhanakal in the same dist. for duty at the Dhanakal Fair, from 14th June to 14th July 1898.

Asst. Surgn. Balis Singh, Gujranwala Sadar Disp., to Dhanakal, Gujranwala Dist., for duty at Dhanakal Fair from 14th July 1898.

Surgn.-Capt. H. Smith assumed charge Civil Med. duties of Amritsar, 19th July 1891.

Rai Sahib Asst. Surgn. Sahib Ditta, Dhangra, to Gurdaspur, where he assumed charge, Civil med. duties, 19th July 1898.

Surgn.-Major G. W. P. Denays, Civil Surgn., Stalkot, privilege leave for month and 24 days, from 15th July 1898.

Surgn.-Capt. E. V. Hugo, 81st Punjab Infy. is placed in charge of Stalkot, from 15th July 1898.

CENTRAL PROVINCES GOVERNMENT.

Hosp. Asst. Lakshman Kesho is dismissed the service, by order of the Chief Commr., from 16th June 1898.

Hosp. Asst. Hashmat Ali, Hinganghat Branch Disp., Wardha dist., to do duty under Officer in civil med. charge, Wardha.

Hosp. Asst. Hashmat Ali, to do duty under Civil Surgn. of Nagpur.

Hosp. Asst. Sayid Mehdi Husain, on plague duty at Itarsi, to do duty under Officer in civil med. charge, Hoshangabad.

Hosp. Asst. Muhammad Haniff, on plague duty at Nagpur, to Behr Branch Disp. Balaghat dist.

Hosp. Asst. Muhammad Amir, Behr Branch Disp., to do duty under Officer in civil med. charge, Balaghat.

Hosp. Asst. Murikihar, doing duty under Civil Surgn. Jabulpore, to the Civil Sta. and Police Hosp., Jabulpore.

Hosp. Asst. Mohan Lal, Civil Sta. and Police Hosp. Jabulpore, to the Disp., at Patana.

N.W. P. AND OUDH GOVERNMENT.

Asst. Surgn. Tarak Nath Ghose, Sadar Disp., Saharanpur, privilege leave for one month, from 8th July 1898.

Hosp. Asst. Muhammad Abrar Hussain, Manglaur Branch Disp., Saharanpur Dist., to hold charge, Sadar Disp., Saharanpur.

Asst. Surgn. Shankar Lal, Sadar Disp., Etawah, to hold charge, civil med. duties of that dist.

Surgn. Capt. J. Morwood, Civil Surgn. Shahjahanpur, to hold visiting med. charge of Hardoi, 8rd July 1898.

ASSAM GOVERNMENT.

Hosp. Asst. Nil Kanta Sen, a Supery., Kamrup dist., to Lakhimpur dist., Dibrugarh Coolie Depot, 5th June 1898.

Hosp. Asst. Nil Kanta Bhattacharjya, Dibrugarh Coolie Depot, to Naga Hills dist., charge of Tamu Mily. Police out, post, 6th July 1898.

Sheikh Abdul Gafur, on probation for six months, a Civil Hosp. Asst. in Assam, to Sylhet for duty as a Supery. under Civil Surgn., from 12th July 1898.

Sick leave for one month, is granted to Hosp. Asst. Kotlavar Guba, Jagi Disp. Nowgong dist., from 18th July 1898.

Hosp. Asst. Brajendra Mohan Goswami, a Supery. Darrang dist., to Nowgong dist., Jagi Disp., from 18th July 1898.

Hosp. Asst. Sheikh Abdul Gafur, a Supery. Sylhet dist., to Baniyachong Disp. in that dist. from 19th July 1898.

Mahomed Ismail, is apptd., on probation for six months, a Civil Hosp. Asst. in Assam, to Dhubri as a Supery., from 22nd July 1898.

Sick leave for four months, is granted to Hosp. Asst. Mahim Chandra Dasia, in extension of the four months' leave granted, 16th May 1898.

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Re. 1 for subscribers and Re. 2 for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTHS.

GREEN.—On July 1st, at Folkestone, the wife of Douglas Green, M.B., London, Surgeon-Captain I.M.S., of a daughter.

BOOKER.—On the 2nd August, 1898, at Dunga Gali, the wife of Brigade-Surgeon-Colonel Booker, I. M. S., of a daughter.

MARRIAGE.

DUCKWORTH—BUCHAN—20th July, at St. John's Church, Bangalore, by the Rev C. H. L. Wright, Walter Ernest Duckworth, L.R.C.P. and S., Edinburgh, L.F.P. and S., Glasgow, fourth son of the late Surgeon-Major F. J. Duckworth, to Elizabeth Scharlieb, eldest daughter of St. John Buchan.

DEATH.

KERIN.—On the 3rd August, 1898, at Neemuch, Central India, William Henry, dearly loved child of Surgeon-Major M. W. Kerin, Army Medical Staff, aged 9 months and 20 days.

NOTICES TO CORRESPONDENTS.

Z. Y. K. (Manipur).—Your report will appear in our next issue.

G. F. (Calcutta).—The facts you report concerning "Numerous abortions by misadventure in a public hospital" will after due enquiry be published in this journal. The story of the pregnant lady who inadvertently had a stem introduced and who wore it for four months without an abortion occurring, is a remarkable instance of how a clever gynecologist can very easily make a mistake.

M. E. (Calcutta).—We have received your notes concerning the Eden Hospital and shall publish them after proper investigation. The fatal operation on Nurse Voss and the fatal results of the operation on the "six-weeks' bride" are noted.

F. O. G. Your case is a hard one, do nothing in haste, bide your time.

F. B. (Calicut).—Many thanks for your paper, it will appear in our next number.

G. F. (Murree).—We believe that as soon as Surgeon-Major Hodgkins returns from leave, Surgeon-Captain Wade will make over the monies and accounts of the Warrant Medical Officers' Provident Fund.

M. P. V. (Barrat).—Asks for a prescription for checking the formation of premature white hair on the head.

A. S. Many thanks for the Punjab University papers. We shall try and use them.

Kanai Lal Chuckerbutty of Khowang, says the following prescription is infallible as a cure for Scabies—Zinc oxide 3ii, Thymol gr. v. Olei eucalypti, min. v. Olei olive ad ʒi. Wash and dry the parts and apply this lotion morning and evening.

ORIGINAL ARTICLES.

INFANT FEEDING.*

By GEORGE CARPENTER, M.D., (London).

Senior Physician to Out-patients at The Evelina Hospital for Sick Children, London.

I NEED not impress upon you the importance of infant feeding, or apologise for having selected this subject, rather than a clinical demonstration on cases of interest in the wards of the hospital. Such sink into insignificance in comparison with the difficult problem I have selected. It is a problem which all of you are called upon daily, almost hourly, to solve, and that being so I venture to think that a practical demonstration on the subject would prove of sufficient interest, and repay you for an omission which my medical and surgical colleagues will fill very worthily. The natural food of an infant is, of course, the mother's milk, and all healthy mothers should feed their infants from the breast. It is one of the greatest privileges of maternity to feed its young from its own body. A healthy mother, who, for the sake of the contour of her chest, or because of the necessarily enforced abstinence from gaiety, passes her offspring to the care of strangers for its nourishment, ought to be severely censured. Moreover, nursing is beneficial to the mother; it stimulates her uterus, and is a great preventive of future harm to that organ. But just as it is so desirable that a healthy mother should nurse her offspring, so it is most undesirable that a mother suffering from serious organic disease should attempt to perform that function. I would here mention phthisis and any tuberculous affection of the mammary glands as a contra-indication to nursing. Those in whom there is a strong family history of insanity had better not nurse their children, at any rate nursing should not be carried to such an extent as to undermine the general health. The fact must never be lost sight of that the mind has a great influence for good and evil on the body of the mother, and so on the production of milk. Emotional disturbances of all kinds are most harmful, and may make the milk actually poisonous to the infant. The child should be placed to the breast as soon as the mother has recovered from the fatigue of the labor, say in three or four hours after her confinement. If there is no milk at first, wait for a few hours until it is secreted, placing the child at the breast every three hours.

Do not give gruel; a little sugar-water may be given if necessary from time to time. As soon as the milk is secreted apply the child alternately to each breast, even through a preference is shown for one only. The child during the first week should be suckled every two hours, between the hours of 5 A.M. and 11 P.M., and only at fixed intervals. If the child be too weak and puny to take the breast, then it will be necessary to feed it at frequent intervals by teaspoonfuls, using either a sterilised mixture of cream and whey, or a peptonised humanised cow's milk, or a modification of Gaertner's milk, which I will presently mention. Cream and whey mixture is prepared as follows:—

Ordinary cream (20 per cent.)	1	fld. oz.
Whey	2	"
Peptonised milk	1	doz.

* Approved from the *Edinburgh Medical Journal* by request.
 † Letter delivered to the Post-graduate Class.

This should be sterilised for half an hour.

The whey is prepared by adding Fiebold's essence of pepsin to fresh milk, which is to be gently warmed. When the milk is set, break up the curd quite small, allow it to settle, and then carefully strain it through several folds of muslin, finally squeezing the contained curd, so as to extract all the moisture.

During the period of nursing several important problems will arise. For instance, should a mother continue to nurse when she again becomes pregnant? Assuming that the mother and child are healthy, the child need not be weaned until the sixth month of pregnancy. Should, however, the double drain on the mother's constitution prove harmful to both of them, shown in the case of the child by gastro-intestinal disturbances, then weaning had better not be delayed. There is also just a possibility that the reflex effect on the uterus may lead to a miscarriage. Should any tendency to such a mishap be discovered, then the child must be fed artificially. Another point for consideration is that menstruation sometimes causes gastro-intestinal disturbance in the infant, said to be due to an increase of proteids in the milk. If this should occur give the infant a little boiled water before feeding, and reduce the meat diet of the mother. But there are some mothers who are only capable of partially feeding their offspring. What should be done? The breast milk should be supplemented by Borden's cream food or Gaertner's humanised milk, which I shall presently discuss, or a modification of cow's milk, previously determined by a chemical analysis of the mother's milk. If analyses of the mother's milk are decided upon, it should be drawn off by the breast pump five minutes after the child has been placed to the breast.

When a mother from various causes, is quite unable to suckle her child, two courses are open to you, namely, the employment of a wet-nurse, or the use of some modification of cow's milk. Of the alternatives, nothing can compare with a healthy wet-nurse, if her milk is suited to the digestive peculiarities of the infant to be reared. The fact that the wet-nurse should be strong and healthy and free from disease need hardly be dwelt upon, or that a careful medical examination will be necessary before engaging her. She should be between 20 and 30 years of age, and if the foster child is strong and vigorous a primipara may be selected, but should it be weak and puny, a multipara, as the milk will not be so difficult to digest. If her baby be strong and healthy, this will not be a point in her favor. She should not have been recently confined, as the colostrum is undesirable. It will not be a drawback if there is a difference of two or three months between the ages of the children, and in one respect it will be an advantage, as the wet-nurse's child will have shown any symptoms of congenital syphilis by this time, if the disease be present. Of course no syphilitic child can be allowed the advantage of a foster-mother. The treatment of the nursing-mother and the wet-nurse demands your careful attention. A plain mixed diet, with slight excess of fluids and meat above what she has been in the habit of taking, will be found ample. A small quantity of alcohol may be taken, if she has been accustomed to it; otherwise it is unnecessary. Alcohol in small quantities increases the

quantity of fat in the milk. Over-feeding and an excessive meat diet will make the milk so rich in proteids as to be quite indigestible. She should take exercise every day, and seize every opportunity of being out in the fresh air. You must not lose sight of the fact that various drugs, some of them of a poisonous nature, pass into the milk, and upset or perhaps even poison the child. Saline purgatives are not desirable, as they are likely to stop the milk. The health of the nursing-woman naturally requires attention, and dyspeptic troubles, or anæmia, will necessitate the appropriate treatment. If a wet-nurse is selected, she must not be allowed to visit her child, but the mother whose child she is nursing must make it her business to see that the child is properly cared for, as an anxious fretting wet-nurse will not produce good milk. No wet-nurse should be allowed to dose her charge on any pretence whatever. The administration of opium is not unknown. When should the child be weaned? The breasts, as you are aware, begin to fail at various periods of nursing, but no infant should be nursed longer than the first year, even under the most favourable circumstances, as rickets will surely result. When weaning has been decided upon, it should be done by degrees, the artificial food selected gradually taking the place of the breast milk. The process should extend over a period of one month, and at the end of that time the mother should send the child away, or leave it for a few days. Do not wean a child when he is cutting a tooth; avoid if possible the very hot season of the year, for fear of summer diarrhoea; and postpone it if he has just recovered from a severe illness. In the event of a mother being unable to nurse her infant, and in the absence of a wet-nurse, what artificial food can be recommended? There is but one answer to this question, and that is, cow's milk. Chemical analysis of healthy human milk shows that it is composed of the following constituents:—

Fat	4 per cent.
Proteids	1.2 "
Milk-sugar	7 "
Salts	0.2 "
Water	87.88 "

Cow's milk, on the other hand, is formed as follows:—

Fat	3.75 per cent.
Proteids	3.76 "
Milk-sugar	4.42 "
Salts	0.68 "
Water	87.39 "

From these tables it will be seen that cow's milk is richer in proteids and salts but poorer in sugar; therefore, in substituting cow's milk for mother's milk, we always dilute with water, to diminish the percentage of proteids, which are so apt to produce indigestion. But in doing this we are diminishing the percentage of fat and making it still poorer in sugar. Hence arises the necessity for adding sugar and cream. But treat cow's milk in whatever way you will, it is only a makeshift, and cannot be made to exactly resemble mother's milk chemically; the curd is different, it is not fully digested, it is also lacking in albuminoid, which is present in mother's milk. We must not lose sight of the fact that the milk sold in cities is more often than not stale, that it contains many impurities and is possibly contaminated with disease germs. Not

only is this the case, but many dairy companies use boracic acid or other chemicals to preserve the milk; in other words, that the consumer may be able to obtain it as stale as possible. Boracic acid is often added in such quantity as to make the milk unfit for infant consumption, owing to the indigestion it produces. Apart from such contaminations and adulterations, cow's milk differs enormously in composition, according to the health of the animal, the time it has been in milk, and the quality of the food; hence the advisability of taking the milk from a mixed herd of cattle rather than from one cow, which was once the fashion. The milk of other animals can of course be used, but there is no advantage in this, as their milk will require modification to imitate human milk. Milk, as soon as it is received at the house, should be placed in a clean vessel, filtered through absorbent cotton-wool to remove gross impurities, and then sterilised to free it from the various germs with which it is contaminated. A reliable apparatus for sterilisation is *ATTG's*,¹ which has the merit of being cheap as well as effective. The milk should be sterilised in the separate bottles provided with this apparatus sufficient for the day's consumption, at a temperature of 100°C. for a period of half an hour. After sterilisation the bottles must be kept in a cool place, free from all sources of contamination. Each bottle is to be unsealed and an indiarubber teat affixed, when the baby is about to be fed.

In out-patient hospital practice, as also in the poorer neighbourhoods, we frequently have to rely upon an unsterilised cow's milk, suitably diluted with water, so as to reduce the quantity of the proteids. A mixture of one part milk and two parts sugar-water, the latter of which is made by adding 1 oz. of milk-sugar to a pint of water, approaches human milk in composition, but it is deficient in fat. The deficiency in fat can be remedied by adding 1 drm. of 20 per cent cream to every ounce of the milk mixture, and failing this $\frac{1}{2}$ of the quantity of cream, in the shape of cod-liver oil, should be given to the child. This mixture should be boiled for half an hour, and when it is cool a $\frac{1}{16}$ part of lime-water added to it makes the fluid slightly alkaline. Ordinary sugar may be used instead of milk-sugar, if the proper proportion is observed. In private practice ROTON's cream mixture will be found reliable and very satisfactory. It is a near approach to human milk in chemical composition. For its preparation the ingredients are to be mixed, as soon as they are received from the dairyman in the following proportions:—

Cream (20 per cent.)	...	1½ fluid oz.
Milk	...	1 "
Water	...	5 "
Lime-water	...	½ "
Milk-sugar	...	3½ drms.

I will now call your attention to the method of preparation of GAETNER's humanised milk. The fresh milk mixed with an equal quantity of boiling water is placed in the centrifugal apparatus, the Victoria cream separator. The machine is revolved at such a speed that the outgoing streams become equal. From one spout comes all the cream and half the milk and water, and from the other spout the remainder. The dirt remains in the machine. All the fat is thus obtained, half the proteids, half the

¹ The percentages of fat, according to Frohlich, in 61 per cent. milk: 3.76 per cent.; Leds, 4.1 per cent.; Hoffmann, 4 per cent.

¹ This can be procured from Dr. Robert Goeman, Webster House, Webster Place, London, W.C.

milk-sugar, and half the salts. To bring the sugar to the required standard, 5½ drms. of milk-sugar are added to every pint of this mixture before bottling. It is then sterilised in the bottles, which contain the milk ready for consumption. Should half the original proteids be still too large for the digestive capabilities, the mixture, before the sugar is added, can once more be diluted with boiling water and again sent through the centrifugal cream separator, thus obtaining all the fat, one-fourth of the original proteids, salts, and milk-sugar. In that case a larger quantity of milk-sugar will have to be added, if the human milk standard is desired. The percentage of fat in the GAERTNER milk is always kept at from 8.2 per cent. to 8.5 per cent. The casein of this milk, when it is precipitated by the gastric juice, curdles in a flocculent form in the same way as does mother's milk, and not like India-rubber, as is the case with cow's milk. I have made arrangements with the Friern Manor Dairy Co., of 20, Farringdon Street, E. C., who are responsible for the process in London to dispense a sterilised milk mixture of any desired chemical formula, on receipt of a doctor's prescription. The great importance of this will be readily recognised. It will enable you to feed your infant patients with an approach to scientific precision which has been hitherto unknown in this country. By means of this you can readily vary the quality of the food, according to the digestive capabilities of the child. If you find that the proteids supplied in the humanised milk are still in too great abundance, and induce gastro-intestinal disturbance, all that will be necessary for you to do will be to send your prescription to the office, instructing them that your requirements are, say, 0.5 per cent., or 0.75 per cent., or 1 per cent., of proteids, or any other percentage you may select, in your milk mixture. In the same way you can regulate the quantity of fat in the shape of cream; in fact, select any percentage that may appear desirable should diarrhoea or vomiting from an excess of fat prove troublesome. On the other hand, if the fat supplied be insufficient for the requirements of your patient for a deficiency of fat leads to anæmia and constipation, then you will be able to increase the quantity. The quantity of milk-sugar can also be regulated as required.

It has hitherto been the custom in cases of summer diarrhoea to withhold all milk and feed temporarily on albumin water, but ROTCH, who was the pioneer of the WALKER-GORDON milk establishments of the leading American cities, has found that if the fat is reduced to 1.5 per cent., the proteids to 0.25 to 0.75 per cent., and the sugar to 4 to 5 per cent., the milk agrees very well. For prematurely born infants the GAERTNER milk can readily be adapted to their digestive capacities by reducing the proteids to 0.5 per cent., or perhaps a trifle less. The Friern Manor Dairy Co., at my request have consented to supply all the metropolitan hospitals both outpatients and inpatients, with milk at cost price, on receipt of a physician's order; and doubtless they will be prepared to do the same with your patients should you deem the case worthy of such assistance.

Before leaving this subject, let me tell you that the Gaertner milk is not sterilised to last indefinitely—it should not be kept for a long time. Full sterilisation makes the milk brown from caramelisation of the sugar;

and changes take place in the fat and sugar, which make them indigestible. Further, sterilisation does not destroy germs with absolute certainty, any bacteria that may be left are not necessarily harmless, and proliferating bacteria cannot always be recognised by signs of decomposition. Therefore, sterilised milk should not be kept for too long a period, but should be consumed as soon after sterilisation as possible. Sterilisation appears to rob milk of its antiscorbutic properties, therefore infants who are being fed upon it require careful watching and any suspicion of the onset of scurvy must be combated by the ingestion of orange juice. The WALKER-GORDON laboratories do not sterilise their milk unless compelled, the distances to be travelled determining this. They rely on ice for its preservation for twenty-four hours. There are several other humanised milks on the market, the oldest and best known preparations being those of the Aylesbury Dairy Co., whose milks, I have no doubt, you have frequently used in your practice. LLOYD, in the Dairy of 15th March 1897, calls attention to some samples of humanised milk. In one sample the fat was 1.1 per cent., in another 5.2 per cent., and the sugar 3.5 per cent.; and he calls attention to even worse samples than these, one containing over 10 per cent. of sugar.

The question must frequently present itself as to whether barley-water, or oatmeal-water, or rice-water should be added to milk. These waters certainly have nutrient worth, and cause the curd to split up into fine particles, and thus render it more easy of digestion. If eczema is induced by the use of these, gelatin jelly may be substituted. Barley-water may be added to ROTCH's cream mixture, instead of plain water, if necessary. Prepare it as follows:—Take two teaspoonfuls of ROBINSON'S patent barley and place in a clean jug. Pour on it a pint of boiling water, stand by the fire for an hour, stir frequently, and add a pinch of salt. The same quantity of oatmeal or ground rice can be used in place of the barley. These waters should be sterilised with the milk to which they are added. Should milk be partially or wholly peptonised? As a temporary measure peptonisation of milk is beneficial. It should be reserved for cases where there is troublesome sickness, or diarrhoea, or the digestive powers are exceedingly weak, and then only to tide the infant over its illness. If it is persisted in, the infant's gastro-intestinal glands will not develop properly, and the seeds of dyspeptic troubles in after life may be sown in infancy.

This question also must frequently present itself to your minds, "What can be urged in favour of the use of condensed milk?" It does not "turn" quickly, the curd is digested better because it is not so thick, and it is convenient when travelling. The best brands are "The Milkmaid" and "The Viking," but to bring them up to the human milk standard it will be necessary to add 1 drm. of sterilised 20 per cent. cream to every fluid ounce of these when mixed with water. The former also requires 1 drm. of milk-sugar to every 1½ fluid oz. when mixed with water and 1 drm. to every ½ fluid oz. of the latter when so mixed. In both cases there is a loss of phosphate of lime salts. It has recently been ascertained that Swiss cows are tuberculous to a far greater extent than the cows of any other country, namely, 35 per cent. of all the cows. Swiss milk

in, as you are doubtless aware, evaporated in vacuo and therefore not sterilised, consequently the tubercle bacilli are not destroyed. There are several dried milk foods on the market, and I now present for your inspection those of MESSRS. Allen & Hanbury. Dried milk foods are small in bulk, and their proteids are digested with greater ease. They are said to be sterile. No. 1 is a human milk imitation prepared from cow's milk. It is called "The First Food for Infants," and is recommended to be used during the first three months. No. 2, called "The Mother's Milk Food," stated to be for use from 3 to 7 months of age, is prepared in the same way, but contains in addition soluble starch derivatives and sugar, also albuminoids and salts extracted from whole wheat-meal and barley-meal. I pass round for your inspection Nos. 1 and 2, and also the solutions made from these according to the directions. Should either of these preparations agree, the addition of fat may be found desirable and advisable in the shape of ordinary 20 per cent. sterilised cream, 6 drms. to every 6 oz. of the fluid, when prepared as directed, of either No. 1 or No. 2.

Mr. C. DRECKHAM, of Steudorf, Germany, also succeeded in making what was apparently a perfect dried milk food. The German navy patronised it, also private ship-owners, but unfortunately it would not keep, as the albuminoids decomposed and the fat went rancid. No preservative had been added, and it appears from this that some chemical preservative is necessary to prevent decomposition in dried milk foods. Of course, as long as they are kept dry, germs cannot multiply in them. Whilst discussing all these methods of infant feeding now in vogue, the scientific advantages to be obtained by the use of GAERTNER's milk, or rather the modifications of the process I have related, must be sufficiently obvious to you, and I need hardly, therefore, advise you to adopt this process in preference to any other I have mentioned. Any system in this country which will give us equal facilities to our American confreres, and enable the medical profession to supervise and control its infant dietetics, should be welcomed, and the advent of the WALKER-HORDON laboratories in Great Britain would prove a positive boon. Such a system permits you to become responsible for the prescribing and ordering of the diet, and not the advertising baby-food manufacturers, who dictate to you in the most barefaced way as to the manner in which an infant should be fed. The alert foodmonger has too long held undisputed sway in the nursery, and it is high time that the bulk of the medical profession in England should wake up and relieve itself of what is a great opprobrium in the eyes of more advanced nations in this respect, and for which, from the generally lethargic attitude it adopts regarding infant feeding, it is certainly responsible. It can only do so by taking an interest in this difficult subject, and by being able to control at will the quantities of the important constituents of the milk which are known to prove a source of trouble in infant feeding. The gain to the infant world will be immense, the huge infant mortality will not be a crying disgrace as it is at present, and value of the knowledge to be gained by the medical profession, working in unison on scientific principles, cannot be over-estimated. The next question for our consideration is, "How often should the infant be fed, and what quantities of food should be given at each feeding?"

The quantity must be determined by the age, the weight and the digestive powers of the infant. For the average infant the following table will be found a useful guide:

	Intervals of Feeding	Number in Twenty-four Hours.	Average Amount each Feeding	Average in Twenty-four Hours.
First week ...	2 hrs.	10	1 oz.	10 oz.
First month .	2½ "	8	1½-2 "	12-16 "
Second month	2½ "	8	3-4 "	20-30 "
Third and fourth months	3 "	7	4-5 "	30-35 "
Fifth and sixth months ...	3 "	6	6-7 "	35-40 "

The quantity of milk administered within these specified limits will depend upon the constitutional peculiarities of the infant, and upon the previously mentioned factors, but the maximum amounts here advised should not be exceeded. The hours of feeding should be between 5 A.M. and 11 P.M., and punctually observed; if they are faithfully adhered to, the child will wake crying at the regular times appointed for its meals.

A word about feeding-bottles, an ascertment of which, along with various rubber teats, I have just received from Paris. The bottles supplied with ALR's steriliser can be recommended, and the soft rubber teats accompanying them can be readily turned inside out and thoroughly cleaned. When cutting these do not make the orifices too small, or the infant will not be able to suck properly, and if too large it will bolt its food, and the inevitable will follow. The old boat-shaped bottle is good, and that supplied by Allen & Hanbury can also be recommended. Feeding-bottles of this class compel the feeding of the infant by the nurse, the tendency to food-bolting is controlled, and the disgusting habit of placing the bottle in the cot with the child is prevented. It is hardly necessary to insist upon chemical cleanliness; therefore the use of bottles with internal indentations, or those provided with tubes, must be strongly condemned.

At the commencement of the seventh month, if the infant is still thriving, the modified cow's milk which has been found suited to it should be still continued, the child taking from 35 to 40 oz. in the twenty-four hours, and there need be no change of diet until it is 10 or 12 months old. It should be fed every three hours, the average amount at each feeding being 8 oz., namely, at 8 A.M., 11 A.M., 2 P.M., 5 P.M., and 11 P.M.

The digestive powers are now quite able to deal with well-cooked starchy foods, if not given in too great abundance. Should the growth of the muscles, the bones, and the teeth prove slow, and the skull bones become softened, then it will be advisable to add cereals to the modified cow's milk. During the seventh, eighth, and ninth months, the weekly gain in weight should be from 3 to 3½ oz., and during the tenth, eleventh, and twelfth months, from 1½ to 2 oz. Increase in weight must not be looked upon as a certain guide, because, as you are aware, rachitic children are often fat and clumsy. Any of the cereals may be given, namely, oats, rice, barley, wheat, or maize

The grains should be washed, then ground into a fine powder in a coffee-mill, and finally passed through a No. 80 sieve. Two tablespoonfuls of the meal to a pint of milk will make a suitable mixture. Great care must be exercised in the preparation of the food which, when thoroughly cooked for twenty minutes in a clean enamelled saucepan, should be placed in the separate bottles of the steriliser; and after sterilization removed to a cool place, from which it can be fetched as required. Should the starch prove troublesome to digest at first, it may be partially predigested by using an artificially prepared ferment, such as Diastol, manufactured by the Standard Malt Extract Co. which is a reliable preparation. This naturally leads us, in conclusion, to the offering of a few remarks on the subject of the various patent infant foods, whose acquaintance you have doubtless made before in many households. Here, on the table, you will see the names of the best-known foods, together with the most prominent features of their composition. When they should be used, when they should not be used, whether should be used under any circumstances, will be apparent to you from the remarks I have previously made on the subject of infant dietetics.

Names of food.	Most Prominent Features of their Composition.
Nestle's Bidge's and Frame food,	Starch (unaltered).
Nestle's, Anglo-Swiss, American-Swiss, and Franco-Swiss.	Starch cane-sugar, and milk. When suitably diluted fat and albuminoids small in quantity.
Carnick	... Starch, sugar, cow's milk, and an animal digestant. When suitably diluted, fat and albuminoids small in quantity.
Mellin	... Sugar and soluble starch derivatives. When mixed with milk, as directed, the fat is deficient, and the albuminoids are more than advisable.
Benger	... Starch, sugar, soluble starch derivatives, and an animal digestant. When mixed with cow's milk there is an insufficiency of fat.
Horlick's malted food...	Dry powder. Human milk imitation. Soluble starch derivatives and an animal digestant. When mixed with water very deficient in fat.

The time at our disposal has unfortunately been short, and the importance and extent of the subject out of all proportion to such a time restriction. Much has been omitted that might have been mentioned, and much only rapidly passed in review which merited greater attention. In spite, however, of the shortcomings, I hope that what I have brought to your notice will prove of assistance to you in your practice.

BLOOD-LETTING AS A THERAPEUTIC AGENT.*

By BRILA OOSMALL, M.D.,

Flint, Michigan, U.S.A.

At the risk of being called an old fogey, I have selected this sanguinary and nearly obsolete subject as the theme of my paper for this occasion, it being no less than one of the lost arts as aptly designated by GROSS. For nearly 2000 years blood-letting was regarded by our most eminent and enlightened men as a potent and efficient remedy in the treatment of disease—a therapeutic agent that could not be dispensed with; and yet to-day it is ignored and treated by most of the profession as a needless thing. Can it be possible that so many acute observers and clever practitioners of past generations could be mistaken as to the potency of this remedy? Is it not possible we are making a mistake in not using it more freely in the closing days of the nineteenth century? What has brought about this extraordinary and radical change of sentiment? Has the type of our diseases changed, as some claim and argue, or has fashion and authority changed?

Was the ancient practice all wrong, and is the present modern practice all right? Dr. JOHN BROWN of Edinburgh and Dr. TODD of London, who are regarded by their followers as great reformers, maintained that the type of disease has changed, and that stimulants instead of depressants are indicated in this day and generation. The late Professor GROSS takes issue with this, and says of all the delusions that called Toddism, has exercised the most persuasive and baneful effects upon civilized society. Concealing itself behind a false position, it has literally enslaved the medical world, entrapping alike the wise and foolish, and sweeping over human life with a force equal to that of the most destructive hurricane. He argues that the inmates of their hospitals were from the lower walks of life, broken down by overwork, privations, and intemperance, consequently were not able to bear depleting remedies. It was from a study of this class of cases that these famous men in an evil hour deduced the absurd doctrine of a change of type in disease. He adds: "I assert without fear of successful contradiction that man's power of endurance in health and disease is not one particle less than it was fifty years ago, when depletory measures of every form was the order of the day; when, in fact, it would have been deemed derogatory to a physician's character to let a patient die without the aid of such remedies." The exploits performed during our late terrible war alone are sufficient to settle this question. Never since man battled with man for national supremacy were there so many rapid, laborious and brilliant marches executed in so short a time as there were on both sides of the line. The exploits of the soldiers of ALEXANDER, HANNIBAL, CESAR and BONAPARTE fade into comparative insignificance by the side of some of our generals. Our laborers, farmers, miners, hewers of wood and carriers of water, mechanics, artisans and professional men evidence no evidence of decline in muscular power or mental endurance. Our soldiers are as hardy a race of men as they were in the days of Sir FRANCIS DRAKE or Captain COOK.

The influence of authority has been great in ages—

* Reproduced from the *Medical Age* by request.

tyrant that has slain thousands. The tyranny of fashion affects the practice of medicine as it does other things in human affairs. The remedies we swear by to-day are neglected and forgotten to-morrow. The pendulum swings backwards and forwards from one extreme to the other. Extremes are always dangerous, and certainly nowhere more so than in the practice of medicine. Half a century ago authority and fashion were responsible for the absurd practice of bleeding, purging, or sweating nearly every patient regardless of ailment. "We cure the sick," says GUY PATIN, a professor in the Royal College of France, "when over eighty years of age by blood-letting, and also infants of not more than two or three months with as much success and as little inconvenience."

Is it any wonder this indiscriminate use of the lancet brought on a reaction? Still it was a hard fought battle that STOKES and others waged against this practice. Listen to the eloquent pleadings of STOKES and SYDENHAM against the authority and against the excessive bleedings, the purgings and sweatings of fifty years ago. "Though his hair be gray and his authority high, he is but a child in knowledge and his reputation is an error. On a level with a child so far as correct appreciation of the great truths of medicine is concerned, he is very different in other respects, his powers of doing mischief are greater, he is far more dangerous. Oh! that men would stoop to learn or at least cease to destroy." In the treatment of fevers the fetters of a thousand years were shattered by SYDENHAM—shattered only to be riveted anew.

GROSS says: "Authority annually slays millions of human beings. Its pernicious effects upon human life, in its individual and collective relations, are seen and felt in every direction, in the construction of our dwellings, in our habits and occupations, in our dress, social amusements, food and drink, and in a thousand ways. Of its malignant influence in our profession, examples daily fall under our observation as the results of pernicious doctrines and practices. Superstition and fanaticism have kept the world in a state of intellectual bondage from the earliest records of society down to the present moment. The spiritism of the present day had its counterpart in the witchcraft of three centuries ago, fortunately without the hangman's halter. Every age has its peculiar absurdities, characteristic of the minds of some of its people. . . . The fate of blood-letting teaches us an important lesson not at all calculated to elevate our pride as men entrusted with the preservation of the health and lives of our fellow beings. It shows what little faith there is to be placed in human judgment and how sadly we are influenced by authority and fashion in a matter pertaining to the dearest interests of society. If I wanted to be satirical, I should say that there are in our profession, as there are indeed in every other, two distinct classes of men—the thinking and non-thinking. The former, whose number is exceedingly limited, accept every novelty or great and sudden change with suspicion, wisely concluding that the one should not be rejected without sufficient cause, nor the other adopted until it has been fairly tested. The non-thinking man, on the contrary, eagerly lays hold of every novelty and seldom stops to seek a reason for his new faith. He adopts it simply because his neighbor adopts it."

Thus it may be seen that fashion and authority is a master that is not easily overcome. Every innovator from Harvey to Lister has been made to feel its force. Yet we opine the influence, the value of authority *per se*, has lessened enormously of late, and the pendulum may swing to the other extreme, to our hurt. HOOKER says practice loves authority. Science must ever hold with Epicharmus that a judicious distrust and a wise skepticism are the sinews of the understanding. And yet the very foundations of belief in almost everything relating to our art rest upon authority. SYDENHAM was called the man of many doubts, and therein, methinks, lay the secret of his great strength. SYDENHAM broke with Authority and went to Nature. His motto was:

"Thou, Nature, art my goddess: to thy laws my services are bound."

A recent writer has said SYDENHAM is unlike every previous teacher of the principles and practice of medicine in the modern world. OSLER says: "SYDENHAM—not LINACRE or HARVEY—is the model British physician, in whom were concentrated all those practical instincts upon which we lay such stress in the Anglo-Saxon character. Thus it is with our authorities. Shifting like the sands in the hour-glass, the dogmas of the schools to-day may be dethroned in the next decade. Truth is usually found between the two extremes and should be totally emancipated from the bondage of error and prejudice. Modern medicine has evidently entered upon a period of exceptional development. He who would keep up with the procession must be up and doing. He must think and reason for himself, and if needs be must step outside of the beaten path and act on his own responsibility."

That the treatment of disease has been greatly simplified, and that we are much better acquainted with the nature and treatment of disease than half a century ago, is universally conceded. The development in chemical science, the studies in pathological anatomy and histology are mainly accountable. We have veratrum viride, aconite and the coal-tar series to combat inflammation that our forefathers knew not of, but yet I contend that blood-letting is a therapeutic agent that ought to be used in cases specially adapted. In all severe and dangerous inflammatory troubles that threaten to destroy life speedily, in my humble opinion this remedy ought to stand at the head of our therapeutic agents to-day, knowing from experience that nothing acts so speedily and energetically in dangerous inflammation as well as in congestion of the various organs. This position I will fortify by a few quotations from eminent writers of the conservative school. As before stated, we cannot believe such eminent observers as GROSS, WOOD WASTON and hundreds of others could be mistaken when they placed blood-letting at the head of the list of remedies in inflammation.

GROSS says in his great work on surgery: "General bleeding may justly be regarded as standing at the head of the list of constitutional remedies for inflammation, as it is at once the most speedy and the most efficient means of relief. . . . Its value was not overestimated by the older writers, who designated it as the *summum remedium* in the treatment of inflammations. Yet strange to say, blood-letting, notwithstanding the high rank it has always occupied as an antiphlogistic agent, has of

late fallen very much into disrepute, particularly on this side of the Atlantic, where it had at one time so many advocates. A great change has come over the profession in this respect in the last fifteen years (written in 1894) and is steadily gaining ground, subverting all our preconceived notions upon the subject and rendering it very questionable in the opinions of many whether blood-letting is really ever required as an antiphlogistic. Whether the change has been the result of a modification of the type of disease or of a more approved method of treatment with other remedies, or simply of the whim or caprice of a few prominent and influential practitioners from whom the rest of the profession have imbibed their views, I am unable to assert, but the fact does not admit of a doubt that more quarts of blood were formerly spilt than ounces are spilt now. Bleeding is no longer the fashion; the operation is denounced by every one. Public sentiment has got to an extreme upon the subject, and we may therefore look for a reaction in favor of the opposite opinion. For myself I can but regret this state of things, because I feel satisfied that it does not rest upon a just and proper basis. If we formerly bled too much, too frequently, too copiously, and too indiscriminately, it is equally certain, at least to my mind, that the operation is not often enough resorted to at the present day. Many a deformed limb, blind eye, enlarged spleen and crippled lung bear testimony in every community to the justice of this remark."

WATSON in his *Practice of Physic* says: "Of all *direct remedies* of inflammation, the abstraction of blood, or blood-letting, as it is called, is by much the most efficient and important." Again he says: "The great remedy in acute and dangerous inflammations is blood-letting, and when this remedy is used at all, it should be used freely so as to produce a decided impression, and its efficacy will always be greater in proportion as it is applied in the early stages of the inflammation."

WOOD in his *Practice of Medicine* says: "In pneumonia in persons with vigorous constitutions bleeding is the most efficient remedy. No disease bears the loss of blood better than open, well developed pneumonia." He also says under general remedies in inflammation: "Bleeding to meet the first two indications; no remedy is so efficient as bleeding. In all times blood-letting has been recognized as a most efficient remedy in inflammation, and the experience of so many thousands who have employed it, cannot have been mistaken on so simple a point of observation. My own personal experience with the remedy is certainly altogether in its favor. Having been in my early professional life opposed to the excessive use of the lancet then in vogue, I have had no prejudice in favor of the remedy; and yet I can most conscientiously declare that I have almost never had occasion to regret using it in inflammation, but on the contrary have had frequent occasion to regret that it had not been used more freely. I know as positively as I can know anything from observation, that it is not only capable of relieving inflammation in the early stages, but will often cut it short and lead to prompt convalescence; nor so far as I am capable of judging is there anything in the condition of inflammation at the present time

within the limits of my observation which renders bleeding less efficacious than formerly."

If this be true (and such is my belief), then is it not time to help bring about a reaction? for I am fully persuaded bleeding is again to take its place as a therapeutic agent. Knowledge runs in a circle; history is constantly repeating itself; consequently bleeding will again come into fashion, not, we hope, to be used so absurdly as half a century ago, but judiciously in the robust and plethoric to promote resolution and save tissue in the early stages, when it has been truthfully said by GROSS: "A copious bleeding at the onset of a violent inflammation is gold; at its height, lead; or, to express myself more clearly, life in one case, death in the other."

So much for this phase of the subject. I will now briefly mention some of the diseases to which blood-letting is more particularly applicable. This embraces the inflammations of various organs—pneumonia, pleurisy, inflammations of the brain and its envelope, acute pericarditis, endocarditis, hepatitis, peritonitis, enteritis, cystitis; in short, all of the "itises" too numerous to mention.

Inflammatory troubles are not the only affections in which bleeding is indicated. In puerperal convulsions in a plethoric subject I regard venesection as the sheet-anchor of our hopes. I have been unfortunate enough to have had more than a dozen cases of this terribly alarming and dangerous disease with a small death rate, owing as I think to heroic and copious bleeding followed by strong anodynes and antispasmodics. In certain forms of apoplexy bleeding is very serviceable, as well as in acute asthma. Certain forms of hysteria and epileptic convulsions dependent upon congestion of nerve centers, with a redundancy of blood in the general system, are often benefited by bleeding, so are comas from uremia. An interesting case is reported by Dr. R. W. RICHARDSON, in the *London Medical Times* in a paper "On Blood-letting as a Point of Scientific Practice."

Case 1.—Cupping. In many cases it is not necessary to open a vein to get the remedial effects of bleeding, for the wet cup will often answer as well if not better. For over thirty years I have been in the habit of using the cups (not that of inebrates) freely in a great variety of ailments, and nothing with more speedy and satisfactory results. Well do I remember a case that occurred in my practice when a young and inexperienced man, a few months after I had commenced the practice of my profession. A Mrs. S—had been confined—not a difficult labor—but for some reason she was stricken with paralysis of the left side during my absence on my wedding trip. Dr. DAVIS, an old competent practitioner who had consented to take charge of the case for me, called in Dr. WIXON, and after several days of active treatment gave no encouragement for her recovery. On my return to duty I immediately gave her a thorough wet cupping from the nape of the neck to coccyx, abstracting several ounces of blood. Before I had completed this process she got the use of both limbs that had been paralyzed for more than a week. I need not assure you it created quite an excitement in the village and added

immensely to my reputation, for it was no small thing to out do two such old and experienced physicians who were practising their profession before I was born. Is it any wonder I had confidence in cupping after this?

Case 2.—Another remarkable case which I had a few years later. I had been away on a visit to Flint to see my old classmate, Dr. MURRAY, and neglected to take my medicine case with me. I met an acquaintance, who accosted me thus: "Doctor, for God's sake hasten to the relief of Mr. I——just ahead here; they think he is dying. Have sent to FLINT for a doctor. Tell them I sent you, and do what you can for him." I went as directed and found the house filled with sympathizing neighbors. The patient was racked and screaming with pain—was, in fact, not in his right mind. His pathetic cry was: "Boys I am dying; it's too late; the gates of Heaven are shut; I can't get in." Friends and neighbors were in tears, and great excitement prevailed. I told them I was a doctor and would do what I could for him. But lo and behold! I had not a drop of medicine with me, and was ten miles from a drug store. I remembered my cups. I directed them to bring me two of the largest glasses they had in the house, some matches, and an old newspaper, and I soon had two powerful cups abstracting blood. He continued his distressing cries for about ten minutes, when he shouted at the top of his voice, "Glory to God, boys; I am inside the gates." I had drawn him in with two ordinary water glasses. It was wonderful what a change of scene took place on that stage of action. Laughter took the place of crying, and the young doctor was quite a sensation. He had accomplished wonders and without medicine. Several hundred dollars' worth of business in this neighborhood soon followed, where before I was a total stranger, as I lived ten miles away. Is it any wonder I am a firm believer in the efficacy of cupping?

Case 3.—Mr. P——consulted me for a severe and constant pain in right side over region of liver. Had been treated by three good physicians successively for weeks with no apparent benefit. One thorough cupping and the abstraction of a few ounces of blood relieved and cured him without medication.

I could report similar cases—several score—but space forbids. The following severe case of pneumonia will answer to illustrate and emphasize my argument that bleedings, general and local, are potent therapeutic agents that should be resorted to far more frequently than is the case at present.

Case 4.—Was called to see Mr. C——, a strong and robust butcher stricken down suddenly with a severe pneumonia of the left side. I immediately abstracted several ounces of blood with the cups, which greatly relieved him and broke the force of the disease. A week

later he was attacked in the other lung. Again I resorted to the cup on this side, with the same result. Before he had recovered, from this double pneumonia he had a severe attack of enteritis, which was followed by acute inflammation of the kidneys, and yet, strange to say, he recovered from this three months' siege and lived several years. I am fully persuaded the abstraction of blood in the start was the prime factor in his recovery, for several of our prominent citizens succumbed to this dangerous disease in the hands of others during his sickness.

A few words as to my method of cupping and I have done. I have tried all sorts of apparatus, but the best is an ordinary water glass of good size, with smooth and thick rim. I ruffle up some ordinary newspaper and light it and let burn for a few seconds in the glass, then apply it quickly. For a scarifier I use a thumb lancet or an ordinary bistoury from my pocket case, consequently I am always prepared if my cupping case happens to be at home when wanted, as is quite apt to be the case.

—:—:—

SOME FORMS OF RECTAL DISEASE.*

By H. GREENWAY HOWSE, M.S., Lond. F.R.C.S.

Vice-President of the Royal College of Surgeons; Surgeon and Lecturer on Surgery at Guy's Hospital, Consulting Surgeon, Evelina Hospital for Children; late Examiner in Surgery, University of London.

THIS coachman, aged 54, said that on the Saturday before admission to hospital he felt an itching about his ischio-rectal region, followed by pain which particularly affected his left groin and then returned to the ischio-rectal fossa. When admitted, he still complained of pain and there was a sense of fluctuation that pointed to pus collection; but a few hours before I saw him the abscess burst, discharging an exceedingly fetid pus and as there was still a good deal of swelling we had to put him under A. C. E. anaesthesia to enlarge the aperture and properly drain the cavity. A free incision parallel with the left side of patient's anus was followed by a farther copious discharge of pus and showed that portions of the skin and underlying tissues had undergone complete gangrenous inflammation. In these cases the inflammation is often so acute as to arrest nutrition and induce gangrene by causing complete stasis in the blood vessels of the affected part, and the possibility of this gangrene happening is a strong argument for early incision to relieve the stasis, discharge the stagnated blood, restore the circulation and preserve the nutrition of the part. The suppuration in this case was very extensive, going parallel to the rectum into the pelvis and as it also extended into the opposite ischio-rectal fossa, a counter-incision had to be made on the other side of the anus.

*Abstract of a Clinical Lecture delivered at Guy's Hospital, London.

A gunshot probe passed through the incision ran up a good seven inches and came very near the mucous membrane in one place but failed to find the cause of the suppuration, which was very high up beyond the reach of the finger. Just note how rapidly this pus formed. The whole trouble apparently dated from only three days before and the pain was probably caused by the pus pressing in the direction of the sigmoid flexure giving rise to irritation, and then fortunately burrowing downwards.

In a previous lecture I drew your attention to the connection between ulcers of the rectum, fistulae and ischio-rectal abscesses. If one of these ulcers formed higher up than the internal and external sphincter it would be inferior to the internal sphincter and the lavator ani, all of which parts aid in determining the direction which the suppuration will follow. A suppuration at this point in the pelvic interior will have a tendency to extend upwards because of the difficulty to force its way past the levator ani into the ischio-rectal fossa. Sometimes the pus burrows upwards for 6 to 8 inches or more (before it softens through and perforates the levator ani) and forms a very extensive sac, the contents of which may burst into the peritoneal cavity. But every case of ischio-rectal abscess does not necessarily communicate with the rectum, as there are other abscesses which burrow down and simulate rectal fistulae, and in some diseases connected with the tissues around the caecum or the ileum the pus may be foul, faecal in odour and color and yet have no direct connection with the intestine. This (last) is probably due to the *B. Coli Communis* passing through the unbroken wall of the intestine, and something of this sort may also occur in extensive pelvic suppurations.

Another cause (but rare) of pelvic abscess is suppurative bone trouble in which the pus contains caseating structures and sometimes pieces of dead bone, and the diagnosis may be strengthened by looking for disease of the spine of the sacro-iliac synchondroses.

Prostatic or urinary suppurations or abscesses connected with the uterus or its adnexa may also cause pelvic abscesses.

Rectal ulcerations are more difficult to treat and are much more common in women—married women especially, than they are in men because of the peculiar conformation of the female sexual organs permitting specific vaginal discharges trickling down over the perineum into the radiating folds of the anus, and conveying the infection by continuity to the rectum. Ulcerations of the male rectum are often due to abominable practices but it is not at all necessary that they should rise from the same cause in women.

To treat such ulceration you must first get rid of the septic cause by means of antiseptic vaginal douches, (such as corrosive sublimate, 1—2000, followed by boracic lotion) and when the vaginal discharge is got under control, treat the rectal ulcers with an escharotic, as nitric acid followed by lunar caustic. The nitric acid destroys the virulent material in the granulation tissues on the surface, while the silver nitrate coating the part with a layer of chloride and albuminate of silver, acts as a sealed dressing which protecting the ulcer against re-infection leaves the after pain much less intense. Recovery may be expedited and the parts put at rest by forcibly stretching or dividing the sphincter.

In fissure of the anus which is really painful, ulceration, most usually of syphilitic origin, at the bottom of one of the radiating anal folds, forcible stretching of the sphincter—at best of times a most painful proceeding—by introducing both thumbs into the anus and forcibly separating them till they touch the tubercles of the ischium, generally suffices to effect a cure; but in some cases simple stretching is not sufficient and we must freely divide the anus, cutting backwards nearly to the tip of the coccyx, so as to separate the fibres of the external sphincter and by thus enlarging the anus, the resistance to the passage of hard or scybalous motions is diminished and rest is given to the rectum, which is thus put into the most favorable position for the healing of the ulcers.

A word or two about the treatment of hemorrhoids by clamp and cauterization when the affection is high up. Having chloroformed the patient, induce reflex contraction of the bowel by thoroughly dilating the anus. This irritates the mucous membrane and protrudes the pile, which may then be seized with the fenestrated forceps and drawn forward to permit of the clamp being placed on it and tightened. Then cut off the projecting part of the pile, leaving a good piece beyond the blade of the forceps, after which burn the stump right down to the blades with the actual cautery. Do not use the vulsellum forceps, for not only does a sharp forceps go into the pile and cause bleeding from it, but it may even go through the muscular coat of the intestine which may become included with the pile you are cutting off and thus make an opening into the ischio-rectal fossa, which may result in troublesome and prolonged ulceration or suppuration.

—:O.—

THE DIAGNOSIS OF CUTANEOUS SYPHILIDES.*

By C. F. MARSHALL, M.D., F.R.C.S.,
Late Resident Medical Officer, London Lock Hospital.

The majority of skin lesions met with in syphilis are no doubt comparatively easy to diagnose; but many cases occur which are extremely difficult to decide in the absence of confirmatory evidence, and the more one sees of such cases the more doubtful one becomes.

The main characteristics of cutaneous secondary syphilides, according to the text-books, are: *Polymorphism, pigmentation, absence of itching, and distribution.* Let us first consider these points.

Polymorphism.—This holds good in the large majority of cases, so much so that it is often unwise to make a diagnosis of syphilis in the absence of other syphilitic lesions, if only one type of skin affection is present.

Pigmentation.—This is also usually characteristic, the colour varying from that of raw ham to a copper colour. However, by no means all syphilides become pigmented in this way.

Absence of Itching.—This, although common, is not a universal characteristic. Many syphilides, especially late secondary ones, are accompanied by more or less itching or burning sensations. No doubt this depends to a great extent on the degree of sensitiveness of the affected person.

Distribution.—Secondary syphilides have a tendency to symmetrical distribution. This is especially the case in

* Reproduced from *Treatment* by request.

the earlier eruptions, but the later secondary lesions are much more irregular in distribution. Tertiary ulcerations are also sometimes symmetrical, but much less so than secondary syphilides. The statement that secondary lesions nearly always affect the flexor surfaces of the limbs is incorrect; the extensor surfaces are affected nearly as often as the flexor.

Let us now take the main types of skin lesions, and compare the syphilitic with the non-syphilitic.

ERYTHEMATOUS SYPHILIDE.—The earliest affection of the skin in secondary syphilis is an erythema or roseola, which varies from a faint mottling of the skin to more or less discrete rose-coloured spots. This first appears on the loins, chest, thighs, and abdomen, and soon changes in colour to a grayish-brown. It is often so faint as to escape notice unless carefully looked for.

Diagnosis.—This is seldom difficult. Measles and rubella are of a much darker red colour and more discrete, and are accompanied by more constitutional disturbance, and by other symptoms characteristic of those diseases. I have, however, seen one case which at first resembled scarlet fever, the rash being bright red and punctiform, and situated on the chest, abdomen, and thighs. This case developed into syphilitic miliaria.

MACULAR SYPHILIDE.—This usually forms a connecting link between the roseola and the latter secondary eruptions, such as the papular and squamous, with which they are usually mixed. The spots vary much in size and colour, changing from reddish-brown to hain colour or to grayish-brown.

PAPULAR SYPHILIDE.—The papular syphilide is usually mixed with the squamous, forming the common papulo-squamous syphilide. That is to say, the spots vary from slightly elevated papules to distinctly squamous spots, which in their full development form the so-called "syphilitic psoriasis."

Under this group come the "lichenoid" and "military" syphilides, resembling lichen and miliaria respectively.

Diagnosis.—This depends on the mixed nature of the eruption, the colour and distribution, and the presence of other syphilitic lesions. Apart from these, a pure papular eruption should not as a rule be diagnosed as syphilitic.

SQUAMOUS SYPHILIDE.—As stated above, this usually occurs mixed with the papular syphilide; but sometimes the whole eruption is more or less squamous.

Diagnosis.—Simple psoriasis differs from the squamous syphilide by its distribution on the elbows and knees, and by the abundant pearly-white scales, which, when removed, leave a bright red base. The squamous syphilide, or syphilitic psoriasis, does not especially occur on the knees and elbows, but is scattered over the body; the colour is darker, and the scales less abundant and more easily removed, leaving a brownish-red stain instead of a bright red one.

CIRCINATE OR ANNULAR SYPHILIDE.—This forms a variety of the squamous form, and occurs as a late secondary phenomenon. It occurs most frequently on the trunk and face, where it forms one of the commonest kinds of the so-called "corona veneris" at the junction of the forehead and scalp.

Diagnosis.—This form of syphilide is often difficult to diagnose apart from confirmatory evidence. The textbooks do not give sufficient importance to its resemblance to *tinea circinata*. Many cases of late secondary syphilis, both under treatment or without, develop a circinate eruption at first sight resembling *tinea circinata*. The main differences are, the colour of the syphilide, which however, is often not typical, and the clear centre with spreading edge which is more characteristic of *tinea*. It is also difficult to diagnose from *eczema palmare* when it occurs on the palm of the hand, but differs from this by commencing in the centre of the palm.

Palmar and Plantar Psoriasis are varieties of the squamous and circinate syphilide as a rule, although they vary from a distinct squamous syphilide to a simple erythema, followed by some peeling or cracking of the skin and subsequent pigmentation. These lesions are comparatively uncommon manifestations of syphilis, but when they occur are very characteristic.

VESICULAR AND PUSTULAR SYPHILIDES.—A true vesicular eruption in syphilis is very rare, although occasionally met with. Syphilitic eczema, if we may use the term, is of slow progress, characterized by the absence of itching and weeping, the presence of pigmentation of the skin, and the association with other syphilides of a different type.

Diagnosis.—Practically, the only vesicular and pustular eruptions likely to be confounded with syphilis are varicella and variola.

Varicella occurring in an adult may suggest syphilis, especially when the vesicles occur on the penis, and become irritated, thereby suggesting primary venereal sores. (This occurred in one case which I had the opportunity of seeing.)

Mild variola, occurring in an adult who has been only vaccinated when a child, may be mistaken for syphilis; but the absence of other signs, and the uniform nature of the eruption, should make diagnosis easy.

Ecthymatous Syphilide is a further development of the pustular, and usually occurs only in neglected and debilitated subjects. It is usually mixed with other syphilides and is a stepping-stone to the next syphilide.

RUPIA.—This is a well-known and characteristic form of syphilide, occurring usually in persons who are broken down in health or who have neglected treatment. It commences either as a pustular eruption, which rapidly becomes ecthymatous, or as a primary bullous eruption, soon becoming purulent. In either case the characteristic sharply-cut ulcers are soon developed. These become covered with scabs, which as the ulcer spreads become piled up in the well-known form of a limpet-shell. There can be no mistake in the diagnosis of these cases.

BULLOUS OR PEMPHIGOID SYPHILIDES.—Pure "syphilitic pemphigus" is almost unknown in adults. In infants it occurs as a manifestation of congenital syphilis, and usually affects the palms of the hands and soles of the feet. In adults, practically the only bullous syphilide is that preceding rupia.

PIGMENTARY SYPHILIDE.—There is apparently a true pigmentary syphilide apart from the stains left by previous eruptions. This consists of irregular pigmented spots, discrete or confluent, the skin between the spots appearing abnormally white. It occurs chiefly in women, and is usually situated on the neck.

TUBERCULAR SYPHILIDE.—This consists of convex projections, or tubercles, of the skin of a gummatous nature, occurring in late secondary or tertiary syphilis. They often ulcerate and coalesce, forming the so-called "syphilitic lupus."

Diagnosis.—This has to be made from lupus, which is, however, of much slower growth, and is usually present in childhood or adolescence, and is characterized by the presence of the "apple-jelly" deposit of tubercle in the skin.

Subcutaneous Gummata are common in late secondary and early tertiary syphilis, especially on the front of the leg over the tibia. They have to be diagnosed from rheumatic nodules, which is usually not difficult, as they seldom occur without other signs of syphilis.

Having considered the main groups of syphilides, let us briefly pay attention to a few other points concerning cutaneous syphilis.

CONDYLOMATA.—These, although coming under the head of popular syphilides, are so characteristic that they may be considered by themselves. They arise as red maculae, occurring on parts of the body naturally moist, viz., about the vulva and anus and inner side of the thighs in women, and about the anus and scrotum in men. These spots soon become raised flat papules, covered with an overgrowth of epithelium, which becomes thickened and sodden, owing to the moisture of the situation.

Sometimes they become chronic and hard from fibrous induration.

Diagnosis.—This has to be made from venereal warts. The warts differ in being much more irregular and pedunculated when occurring in large masses. Small warts cannot be mistaken. Sometimes warts develop on the top of condylomata, forming the so-called warty condyloma, which is probably a mixture of both.

ACNEFORM ERUPTIONS.—An acneform syphilide is uncommon, and is usually mixed with other syphilides. When it occurs it differs in colour from simple acne and in the absence of comedones.

PURPURA.—Secondary syphilides sometimes become purpuric, but this is usually due to other constitutional affections.

ALOPECIA.—According to Crocker, alopecia may be due to four causes: (1) A general thinning of the hair from malnutrition; (2) a patchy alopecia resembling alopecia areata; (3) a circumscribed eruption from the implication of hair follicles in previous syphilides affecting the scalp; (4) tertiary ulceration destroying the whole thickness of the skin.

Alopecia is comparatively common in secondary syphilis, and appears to be more common in women.

The diagnosis depends on other signs of syphilis being present.

AFFECTIONS OF THE NAILS.—Onychia and paronychia sometimes occur in syphilis. The former is due to malnutrition, the latter to an extension of a squamous syphilide to the matrix, or to gummatous infiltration.

SYPHILITIC ULCERATION.—This may follow (1) cutaneous pustules; (2) cutaneous and subcutaneous gummata; (3) rupia. The ulcers are usually circular; with well-defined sharply-cut edges and a grayish base. They often extend on one side, while cicatrization takes place on the opposite side. Confluence of several ulcers causes the characteristic "serpiginous" ulceration. Gummatous ulcers from deep excavations called "crateriform."

Diagnosis.—The diagnosis from lupus has already been mentioned. Gummata differ from tubercular nodules in having a greater amount of fibrous tissue and a less tendency to caseation than tubercle. Tubercular ulcerations are more irregular, and usually have thin, ragged and undermined edges.

SYPHILIDES MIXED WITH "ITCH."—By "itch" I include both scabies and pediculi corporis. A combination of eruption caused by one or both of these, and mixed with secondary syphilides, is often difficult to diagnose, especially as they usually occur in dirty subjects. Each eruption appears to be modified by the other, and some time often elapses before the syphilide can be diagnosed.

In all cases of "itch" which do not clear up under the usual treatment, syphilis should be suspected, and antisyphilide treatment commenced. This usually clears up the diagnosis, and both syphilide and itch rapidly disappear.

SYPHILIDES MIXED WITH SIMPLE SKIN LESIONS.—It sometimes happens that a patient with some simple skin affection, such as eczema or psoriasis, contracts syphilis. In such cases the resulting secondary syphilide becomes mixed with and modifies the nature of the simple skin affection, so much so that diagnosis is often difficult, and depends mainly on the results of treatment. A mixed eruption of this kind will become differentiated under antisyphilitic treatment, bringing to view the simple skin affection, which had, so to speak, been buried in the cutaneous syphilide.

A NUMBER OF FRACTURE.

ABDOMINAL PREGNANCY: LAPAROTOMY: RECOVERY.*

By ELIZABETH BIRLEY, M.D.,
Senior Physician to the Lady Atchison Hospital
for Women, Lahore.

THE following case seems worthy to be recorded. D., HINDU, was admitted at 11 P.M. on 24th February, 1898, pregnant for the third time. She stated that she had been in labour twenty-four hours. She was much deformed, could not stand erect, and when lying down could not extend her legs.

On internal examination the pelvis was found extensively deformed, both at the inlet and outlet. The true conjugate measured less than two inches. The vaginal roof was torn to the extent of two inches, and from this laceration the edge of the placenta was protruding. The limbs of the fetus could be easily felt through the abdominal walls. The patient was very weak and exhausted, she having lost much blood.

The walls of the abdomen were cleansed with hot water and soap, and turpentine: the woman was put under chloroform, which she took well. An incision was made three inches from the symphysis pubis to two inches below the ensiform cartilage. On opening the abdomen a large quantity of blood-stained fluid escaped. The fetus, which had been dead some time, was easily extracted with the placenta. The abdomen was washed out with 1 in 10,000 perchloride lotion; the abdominal wound closed in the usual way: a glass drainage tube left in the lower angle of the wound, and a second drainage tube left in the laceration in the vaginal roof, the vagina packed with iodoform gauze. She was very weak, and the extremities cold. She was given a hypodermic injection of ether.

For the first few days she remained weak and exhausted, her temperature remaining slightly below normal. On the fourth day the drainage tube was removed from the abdominal wound, and from that date she made a good recovery. She was discharged cured on 2nd April, being kept in hospital for the last ten days owing to an attack of bronchitis.

The question that seems difficult to answer is, How was the laceration caused in the vaginal roof? The patient informed us that she had had no treatment before she came into this hospital.

I was very ably assisted in the operation and after-treatment by my assistant, Miss JARDINE, L.M. and S. Madras. The chloroform was given by Mrs. PAUL, the house-surgeon to this hospital.

INJECTION OF ALCOHOL IN THE TREATMENT OF GUINEA WORM.†

By SURGEON-CAPTAIN T. H. FOULKES, L. M. S.
Salem, Madras.

I HAVE recently had a number of cases of guinea worm under my care. Although these cases seem but trivial,

* Reproduced from the British Medical Journal by request
† 1894.

the worm was easily detained by them in our military hospital for a considerable time. The idea occurred to me that the worm under treatment might be shortened if some hardening agent were applied to the worm in order to lessen the chance of breaking it and also to allow of more force being used in drawing it out. It seemed probable that if alcohol were injected into the worm with a sufficient amount of force the alcohol would permeate it and harden its substance wherever it came into contact with it, and that a certain amount of shrinkage would take place which would loosen the worm from the surrounding tissues.

The first case on which trial of this process was made had been under treatment for about a fortnight, the usual course being pursued of rolling up an inch or two of worm daily round a piece of paper. I then injected alcohol into it, and allowed about half an hour for it to take effect. The remainder of the worm (about 2 feet) was then easily drawn out in a few minutes. Several other cases were equally successful, both in my own hands and in those of some of my colleagues. I subsequently found that the alcohol did not always reach the farther end of the worm, and the same amount of with-drawing force being kept up, the part of the worm which was not pickled was liable to snap off. To remedy this a little fuchsin was added to the alcohol. This dyed the worm a fine red colour, and showed how far the alcohol had penetrated, further injections could then be made into the uncoloured part of the worm.

An additional advantage of this method of treatment is that if the worm by any mischance breaks and retracts, no suppuration occurs, the wound heals up, and the remainder of the alcoholised worm is absorbed like an aseptic ligature. I observed this in several cases.

Unfortunately my supply of guinea worm cases came to an end before I was able to test the treatment as fully as I could wish, so I write this as a suggestion for those who may be more favoured with cases than I have been and may like to try this process.

:O:

UNDESCENDED TESTICLE, GIVING RISE TO DISTRESSING SYMPTOMS DUE TO SARCOMATOUS DEGENERATION, CASTRATION: RECOVERY.

By JAMES R. WALLACE, M.D., F.R.C.S.I.

Formerly Resident Surgeon to the Medical College Hospital, Calcutta.

R. C. an Anglo-Indian, aged 25, short, thick-set, and of good constitution, was born a crypt-orchid, his left testicle having remained undescended from birth. There was always, as long as the patient could remember, a "lump" in the left groin. It had remained absolutely painless till about four months previous to his consultation with me, when he observed occasional acute pains in the swelling and a frequent sense of nausea. In a few weeks the pain became worse, the swelling more enlarged, and there was persistent vomiting, which confined him to his bed for a few days. The symptoms subsided, but with the resumption of his duties, there was a recurrence of suffering. When I first saw him on the 22nd of March, 1898, the lump in the groin was hard, tender and non-fluctuant. The slightest pressure upon it induced nausea. Sulphate of magnesium with tartar emetic in small doses internally, the application of belladonna and glycerine to the swelling, with rest in the bed, gave complete relief, and for three weeks the patient was able to go about his work. On the 25th of April he had a recurrence of all the bad symptoms above described, and finding that the slightest exertion was attended with a return of suffering, he was advised to undergo castration of the undescended and apparently diseased testicle.

Accordingly on the 25th of April he was placed under chloroform by Dr. William O'Sullivan, and I cut down upon the testicle, along the bulk of the dissection with the handle of my scalpel. The main vessels leading to the tumour were ligated and the mass cut off above the ligature. All bleeding points were quickly secured by pressure forceps, so that the patient did not lose more than half an ounce of blood during the operation. The wound cavity was insufflated with iodoform and boric acid, a drainage tube was inserted, and the incision closed by horse hair sutures. Boric gauze dressings were applied and changed on the second day, when also the tube was removed. The subsequent progress was most satisfactory. During the operation I had the skilful assistance of Dr. ARNOLD CADDY, M.B. Eng.

Remarks.—This case is most interesting from the diagnostic value of the reflex testicular vomiting as the characteristic sign of the disease present. On cutting into the testicle after removal, it was found to have undergone purulent inflammatory change, and as the structure of the mass seemed very much altered pathologically, it was sent to Surgeon-Major J. F. EVANS, the pathologist of the Calcutta Medical College, who reported on it as follows:—"I find the tumour which you sent me on the 29th April to be a round-celled sarcoma, with practically no trace remaining of the glandular structure of the organ in which the new growth arose. There is some evidence of inflammatory change and of hydrocele having occurred prior to the formation of the growth." Primary sarcoma of the testis is rare in so young a subject.

:O:

IMPOSSIBLE EXTRACTION OF PLACENTA: DEATH FROM SEPTICÆMIA; MISUSE OF ERGOT.

By ALF. MCCABE DALLAS, L.M., L.R.C.P. & S.,

Assam.

A NATIVE woman, sparsely built, with a smallish pelvis; and whose age was about 22 years, gave birth to her first child at 6 A.M. on the 9th August; the child was full term and born alive. By 10 A.M. the placenta had not come away and a native doctor was called in, and without any particular enquiry he began the administration of ergot and up to about 4 P.M. had given some 5 or 6 doses of 40 minims each of the liquid extract. The placenta still remaining intact. I was sent for, on arrival I found the woman in a state of fear, rapid pulse and breathing, with temperature of about 106°, the labia were fearfully swollen and lacerated and the pain agonising. I immediately put her under chloroform with a view to extracting the placenta, but to my disappointment found the soft parts within so terribly swollen, hot and inflamed, that with difficulty I could only pass my forefinger towards the uterus which was contracted as hard as a rock. After an hour's careful manipulation I had to abandon the effort and propose a Perno's operation which was rejected. The woman was then placed under antiseptic treatment, and the greatest attention paid her. The swelling never subsided and no opportunity presented to give a chance of removing the placenta. The result was as I had anticipated, death after a week from septicæmia. There is no doubt that extensive adhesions prevented expulsion, and a large child caused all the injuries, but the difficulties brought about, were in a great measure due to the misuse of ergot, without proper examination in the first instance. The interest attaching to the case is to inform young inexperienced practitioners of the danger of not satisfying themselves, that retention of the placenta is due merely to inertia, and that no other obstacle exists. Even in a natural confinement some men seem to think a dose of ergot at the end is a *sine qua non*, when as a matter of fact in my opinion it ought only to be given as a distinct necessity.

THE Indian Medical Record.

1st September 1898.

THE ROYAL ARMY MEDICAL CORPS AND THE INDIAN MEDICAL SERVICE.

THE long expected Warrant is now *un fait accompli*, and there is certainly nothing in its terms to throw any light upon the tardiness with which it made its appearance. Many who were somewhat puzzled and uneasy over the delay, persuaded themselves that it was due to the number of minor details and varying interests that had to be considered; if such was the case, the difficulty has been overcome by the simple method of letting them shift for themselves, for in the present Warrant there is nothing to show that they ever existed.

This course may have been adopted owing to the urgent necessity of getting the Warrant out as quickly as possible; the depleted state of the Army Medical Staff was such that it was only with the greatest difficulty the work could be carried on at all, and above all things it was necessary to get a sufficient number of men to compete at the August examination.

To this cause we attribute the issue of the Warrant in its present form, which we believe to be unprecedented in its incompleteness.

It merely states that it has been "deemed expedient to alter in certain respects the conditions under which the officers employed upon the medical duties of Our Army are at present serving", that, "the officers below the rank of Surgeon-Major General serving in Our Army Medical Staff shall be formed into a Corps, together with the warrant officers, non-commissioned officers, and men of Our Medical Staff Corps"; that, "the designation 'Medical Staff Corps' shall be abolished and that the Corps formed as above mentioned shall be styled 'The Royal Army Medical Corps'"; that, "the following alterations will consequently be made in the ranks of the Medical officers of Our Army. Present Rank, Surgeon-Colonel, new Rank, Colonel, and so on to Surgeon Lieutenant with the new rank of Lieutenant." The Warrant bears date, the 23rd June 1898.

Such is the Warrant which has been so long fought for, and the battle has not been without bitterness on both sides. That it ushers in a new and better state of things for the officers of the new Corps there can be no doubt, and we heartily congratulate them on the successful termination of their long struggle.

This Warrant is free from the juggling with terms and the carefully constructed loopholes for rendering it a dead letter which disfigured the previous one, and made it, and justly so, an object of suspicion from its first inception. Every thing is fair and above board, all is clear, plain, and simple, as might have been expected from a statesman of Lord Lansdowne's grasp and ability.

The obstructives in the War Office have shot their last bolt, there are here no traces of their meddling; the main position, the question of rank and titles, has been freely and

ungrudgingly granted, and also the title of Royal has been added by the generous goodwill of Her Majesty, so that all cavillers must now *perforce* be silent.

One slight concession has perhaps been made to the opposition, by the retention of the title of Surgeon-General, but for this, good reasons have been given, and we believe that the compromise has been accepted almost without demur. We can however see nothing in the arguments that have been advanced for refusing to give the senior medical officers in the Army, titles in conformity with those borne by their juniors, and we think that it would have been better to have replaced the title of Surgeon-General by that of General, *tout simple*.

As we had foreseen, no mention whatever is made of the Indian Medical Service, and the Warrant in no sense applies to it. It is stated that the Indian Government has been asked to submit proposals for dealing with it, but what shape these proposals will take, it is quite impossible to forecast.

We have seen it stated in some well informed papers that the Indian Medical Service will also be formed into a Corps; but how this is to be done, passes our comprehension. A Corps presupposes men as well as officers, and where the men are to come from to form the Indian Medical Corps, we do not know.

Two things are certain, first that the title of Royal will not be granted and second that no Corps will be formed.

By some it is confidently stated that according to the precedent of the former Warrant, this Warrant in as far as it relates to the combatant titles, will speedily be extended to the Indian Medical Service, of this we have the gravest doubts. It must be remembered that the extension of the previous Warrant introducing the compound titles to the Indian Medical Service and to the Veterinary Department, was generally looked upon as a small piece of spite on the part of the War Office authorities, like the introduction of the ridiculous title of Brigade-Surgeon Lieutenant-Colonel, it was simply a method of diminishing the value of the Warrant to the Army Medical Staff.

Neither the Indian Medical Service nor the Veterinary Department had ever felt the want of titles, they had never made a grievance of not having them, but the Warrant was gratuitously extended to them, and why? because it was known to be a worthless sham.

No argument from analogy will hold between the Royal Army Medical Corps and the Indian Medical Service. The conditions under which they serve are totally different.

In the existence of the Medical Staff Corps, a body that has always been commanded by them, the officers of the A. M. S. had their strongest claim to combatant titles, their claim was in fact logically indisputable. With the exception of India, the Corps serves all over the world, wherever British soldiers are found: it consists of a large body of warrant officers, non-commissioned officers and men, specially trained in all the duties pertaining to hospitals and nursing, both in peace and war.

The unification of the officers who held command, and of the men who were commanded, into a single Corps, was the only logical sequence of such a system, and the only cause for surprise, is that it was not carried out long since.

It is obvious that the Indian Medical Service can put forward no such claim, and there is no reason whatever that

what has been done in the case of the Royal Army Medical Corps, a purely military body, should be equally applicable to the half military and half civil, Indian Medical Service.

The fact that they have never asked for these titles, and presumably have never felt the want of them, and that plenty of candidates are always forthcoming, places them more on a footing of comparison with the medical officers of the Navy, who do not share in the advantages of any of these Warrants.

At any rate it is a question that is entirely in the hands of the Indian Government. We do not believe that its decisions will be in any way influenced by what has been done for the sister Service, the whole matter will be opened up from the beginning, and argued out on completely different lines.

That the organisation of the Indian Medical Service is clumsy, and that its re-organisation would long since have been taken in hand, had there been any one capable of tackling such a difficult question, is known to all.

The opportunity has come and the attention of the Indian Government has now been peremptorily called to the necessity of doing something, let us hope that it will not be lost.

The whole machinery of the Indian Medical Service is one mass of anomalies, it is a most complete system of the most glaring abuses, and as an agency for advocating and advancing reform and scientific progress it is totally impotent.

From the Director-General down to the Provincial administrators, every official is a mere puppet in the hands of the Civil Service secretaries. Witness the disgraceful incompetence of many of the recent educational appointments in our Medical Colleges; the unsatisfactory working of almost every public hospital: the inefficiency and inadequacy of the service rendered by state-paid medical officers, directly traceable to their being permitted to engage in highly remunerative private practice.

Witness the absence of control and inspection of the medical work done in our hospitals, a dereliction of duty which is so notorious that it has attracted the attention, and drawn down the denunciations of the public press over and over again.

Our Medical Students are imperfectly trained how much, or rather how little time is given to clinical and other forms of practical teaching; and how small a measure of the time of hospital physicians and surgeons is devoted to the welfare of the sick.

Our Medical examinations and diplomas are in a chaotic condition; there is no systematic instruction in Hygiene in our Colleges, and no diploma in public health in the educational system of our universities. Madras has just taken a proper step in this matter.

We are even without a Poisons Act, and a system of Medical Registration!

The disgraceful condition in which we find ourselves in these matters, is entirely due to the absence of power and authority in the Indian Medical Service, and its complete subordination to other departmental administrations.

To whom are we to look for reform, if not to the Director General of the Indian Medical Service, the official adviser of the Government in all medical matters? To keep Medical Education in India abreast of the times, must be

considered the highest of his functions, but of late years the officials occupying this position have signally failed in its exercise.

We cannot wait until another Sir RANALD MARTIN arises. The whole service is decadent; it has sadly fallen off from the glorious traditions handed down to it, its day is past, it is antiquated, no addition of military titles will renovate it, nothing but a clean sweep will suffice, and in the conviction that this will come, if not at once, yet within a measurable time, we rest contented.

—:O:—

THE INDIAN MEDICAL CIVIL SERVICE AS A WAR RESERVE—A HUGE SHAM.

We believe it is argued that it is necessary to support the large civil establishment of the Indian Medical Service as a war reserve, if so there can be but little doubt that it is the most expensive war reserve in existence, and the Government must be weak indeed that cannot devise some more economical scheme.

In the meantime, while not required in our little frontier wars, this wonderful reserve is employed upon the most heterogeneous duties. We have holders of professional chairs at our universities, many of them remarkable for little but their youthful appearance, Heads of Colleges and Hospitals; Sanitary Commissioners, Chemical Examiners; Civil Surgeons etc etc., and in the performance of all these duties, with the exception of managing a large and lucrative private practice, they have for the most part signally failed.

The medical work done in India points relentlessly to the fact that the government has not had good value for its money. By its own acknowledgement the whole system of Medical Education, whether in the universities or schools, all in the hands of the Indian Medical Service, is a failure. Of so low a standard is the education, that the government cannot depend on the qualified men turned out, to even look after plague cases, while the Calcutta Health Officer has to ask, that Sanitary Inspectors be imported from England!

The maladministration of our large civil hospitals has reached such a scandalous state, that official notice has had to be taken of it, in at least one instance, and reforms introduced. In all questions of medical progress or research, we have remained stagnant or have drifted for years, hardly can one lay his finger on a decent piece of work that has been turned out, while the very air is thick with problems of the greatest interest and importance.

There can be no doubt that the Government is not getting good value for its money, and it is time that its eyes were opened and that some other system was introduced.

No progress can be hoped for as long as men who are heavily paid for the performance of other duties, devote the greater part of their time to making money by private practice.

The men who usurp and monopolise the practice in our large cities and towns and in our choice hill stations, are not men who have succeeded by their own individual endeavours. They may be good, they may be the reverse; they may succeed by their merits or in spite of their demerits, but in any case success is assured to them, for they are heavily subsidised, and have the prestige of an official position.

To assert that they are always the best men, is as absurd as it is untrue. If they are the best, they will have plenty of scope for their energies, and occupation for their spare time in consulting practice, to which we should like to see them limited.

Either the Civil Surgeon or the College Professor of the I.M.S. has enough official work to do, or he has not. If he has, then by spending some three-fourths of his time on private practice, he is defrauding his employer. If he has not, then the government is to blame for wasting the tax payers' money in paying a man for being idle.

When the question of the necessity for the existence of a civil surgeon is raised, the number of his official duties put forward by the authorities who are responsible for his appointment, would lead one to believe that he was much overworked. But how are these official duties performed?

Take the one question of sanitation. The civil surgeon is *ex-officio* responsible for the sanitation of his station, and we would like to know how many hours a month are devoted on an average to these important duties, and how many reports are made on the subject in the year.

Sanitation throughout India is of course in a woefully backward state, but in the choice hill stations, one would naturally look for and expect to find something better, but common report says that these choice health resorts are as insanitary as they well can be, and are only saved by the cleansing influence of the annual monsoon.

At the present moment, Ootacamund, one of the fairest spots in the Empire, is a hot-bed of enteric fever. We will not be rash enough to pretend we can place our finger upon the cause, but what appears to be certain is that the lake is in a filthy and insanitary state. No doubt a lavish outlay will now be forthcoming to cleanse it but what we would like to know is, what was the sanitary officer thinking of to let it to get into such a disgraceful state? Filling his pockets with an extra income from private practice and leaving his sanitary duties go to the devil of course!

If the whole of the civil side of the Indian Medical Service was wiped out to-morrow, there would be suitable men forthcoming to fill every vacancy twice over. The India of today, is not as it was formerly, and the Government has seen by its plague importations, the readiness with which medical men possessed of the best diplomas and credentials, are now-a-days prepared to face the climate, and rush out to India for work, even when a fatal disease is added to the exaggerated terrors of a tropical climate.

Suppose this was done gradually, what an immense saving it would be to the overburdened finances of India. It is an error to assume that India cannot support its own doctors. The country has passed out of the stage in which it required to be dry-nursed. Let the Government put its money into its pockets and call for volunteers.

The present is no doubt an opportune time for taking some steps in this direction, when the Government has been called upon to formulate some proposals for dealing with the Indian Medical Service, in connection with the new Warrant changing the Army Medical Staff into the Royal Army Medical Corps.

The prohibition of the competition being granted under this Warrant to the Civil side of the Indian Medical Service would only be ridiculous, and would add to the many anomalies that already exist.

Let us have a Government Military Service by all means, but for a Government Civil Service as a WAR RESERVE the necessity no longer exists, if it existed at all.

SUBSIDISED DOCTORS AGAINST PRIVATE PRACTITIONERS. AN UNJUST MONOPOLY.

WHEN the private practitioners of Mussoorie appealed to the Government to be relieved from the unfair competition to which they were subjected, by the Civil Surgeon, a paid official of the Indian Medical Service, being permitted to engage in private practice, some stir was caused and the matter was freely commented upon in the lay papers.

Some strongly backed up the appeal, while others as might have been expected, skirted or passed lightly over the thin ice, and more or less avoided the discussion of a subject, the merits of which they clearly saw would not be upon their side.

As however time passed on and no satisfactory result appeared, the Council of the Indian Medical Association thought the matter of sufficient importance to engage its attention, and after carefully considering it in all its bearings, addressed on the 16th December 1897, a letter to the Government of the North West Provinces and Oudh, asking for the removal of the just grievances of the Mussoorie practitioners, by the prohibition of private practice to the already well-paid and overworked Civil Surgeon.

The official reply dated the 28th February, not being considered satisfactory, amounting as it did to a simple *non possumus*, another letter dated the 21st May 1898, was addressed to the Government of India setting forth their grievances and asking for redress. True to its traditions of non interference in the matter of State monopolies, the Government of India has now intimated to the Council of the Indian Medical Association, that "it does not find reason to interfere with the system," thus affording another proof of the impotence of the present methods of medical administration in India.

The importance of the question raised is by no means confined to the limited interests of the Mussoorie private practitioners, however much those interests may be and undoubtedly are affected. This is but the straw which shows the way the wind blows and foretells the advent of a storm.

The question penetrates to the core, all the most vital interests of Medicine in India. It affects not only the position of every private practitioner in the country, but also the prospects of all who may contemplate settling in this part of the Empire. It is closely bound up with the matter of reform and improvement in Medical Education; for with the limited openings that exist at present, there is nothing to stimulate progress, or to encourage our students to seek for the higher qualifications and to crown their student career with a British qualification, after a further course of study in the British Isles.

What prospect of advancement; what hope of success is there at present to compensate men for the extra labor and expense that this involves!

This is not as it should be, it leads to stagnation. Healthy and fair competition is good in every walk of life, but the desolating effect of the black system which prevails in medical matters in India, spreads its evil influence far and wide.

Not only is there no opening for those who are born and educated in this country, but English, Scotch and Irish medical men are shut out, as though it were an alien land under a foreign rule.

Owing to their innate aptitude of restlessness, enterprise, and adventure, and none the less to the congested state of the profession in England, graduates and diplomates from that country are continually pushing out and establishing themselves in the furthest and often the most unlikely parts of the realm. India alone closes her door, and to him who turns his eyes in this direction, the warning is given, there is no opening in India; the Indian Medical Service have all the practice in their own hands.

The Indian Medical Service may indeed congratulate itself upon the success which has followed its efforts to keep India as its own special preserve, and in these efforts it has been ably seconded by the Government of India.

As to who have been the gainers in the transaction, there can be no doubt, for it must be patent to every one that it is *not* the Government.

No one can doubt that the permission to engage in unlimited private practice is a strong temptation to perform ordinary routine duties in a perfunctory manner, and that the temptation is in many cases too strong to be resisted we constantly learn from complaints and reports in the daily press.

It is further an anomaly of a most glaring and unfair description, that of all the officials in the service of the Indian Government, the Indian Medical Service should be the only service that is permitted to augment its income by the performance of purely private work. Such an extraordinary distinction as this is most invidious.

Whatever reasons may have existed in the past for this condition of things, it must be clear to anyone who surveys the ground impartially, that they exist no longer. The time is now fully ripe for reforms and we are glad to think they cannot be much longer delayed.

THE COLLINS-UZIELLI CASE. ITS LESSONS AND ITS WARNINGS

It is unnecessary to expatiate upon the amount of publicity which has been given to this case, in which Dr. COLLINS was sentenced to seven years penal servitude for causing the death of Mrs. UZIELLI in the attempt to produce criminal abortion, or to raise the question of the advisability of this publicity from the point of morals or expediency.

The matter is one of interest and importance not to the medical profession only, but to the general public as well. In this respect it is two sided, and the lessons and warnings it conveys are for both sides alike.

Upon no point are the English papers more unanimous than in revealing the extraordinary prevalence of the practice of procuring abortion at the present day, some go

so far as to say that amongst a certain class it has become quite a custom, and that to say nothing of the moral side of the question, its heinousness as a criminal offence, is entirely lost sight of.

Others point to the wide dissemination of advertisements which promise, in scarcely veiled language, a safe and speedy means for getting rid of the products of conception, and accentuate their remarks by the statement, most discreditable if true, and we have no reason to doubt it, that the so-called religious papers, are the worst sinners in this respect.

All this seems to point to a sadly lax state of morals, to a change in the mental and moral standpoint with regard to certain duties and responsibilities, to a process of evolution which has already undergone a considerable amount of development, and which may have to be seriously reckoned with in the future.

But these are questions of general philosophy with which it is not our proper province to deal.

On the behalf of the erring practitioner, it must be remembered that in these crimes, it is one of the general public who is the originator, the doctor is tempted, and so common is this form of temptation, that we see it stated that there are few practitioners who at some time or other are not approached on the subject. Who can be surprised that some are weak enough to yield to the eager supplications of their tempters?

The medical profession cannot, however, follow the tendency of the times in this respect, a higher standard of morality is demanded of it, and to its credit be it said, that amongst the vast majority, the old Hippocratic precept, "I will give no deadly medicine if asked, nor suggest any such counsel," is as binding as ever.

Such cases as these, undoubtedly cast a certain amount of discredit upon the whole professional body, and it is surely a sad sight to see a man prostituting his noble calling, his knowledge and intellectual attainments to such ignoble ends.

That it is frequently done with impunity there can be no doubt, the difficulties in the way of obtaining a conviction before a Court of law are enormous. Where the operation is successful no evidence is as a rule forthcoming, if it were, the woman who sought the abortion would take her place in the dock as an equal offender with him who attempted to produce it.

If a conviction could be obtained under these circumstances it would probably do more to check the unnatural custom, than all the homilies in the world.

That women should be willing in this way to repudiate all their natural instincts and run all sorts of risks to avoid the duties of maternity, is perhaps but one of the signs of the times. It is an unhealthy sign, however, and one that demands the stoutest repressive measures. It does not redound to the credit of our much vaunted progress and civilisation that what was once the highest pride and the paramount duty of woman, should now be looked upon as a bore, or as something to be avoided at all costs.

The legal aspect of this case has a special interest of its own, owing to the Attorney-General's statement of the law in its application to it. According to the letter of the

English law it appears that any one who causes death while in the commission of felony, no matter how accidentally and unintentionally the death was brought about, is guilty of murder.

This construction has however been modified or set aside from time to time by the highest legal authorities. It only wanted Sir RICHARD WEBSTER's dictum to render it completely obsolete.

In the COLLINS' case he laid it down as the law, that if the act by which the death was caused, was "not in itself of necessity dangerous to life," then the jury might find a verdict of manslaughter and not murder.

Surprised as everyone was at the time, by what appeared to be a complete subversion of the law of the land, Sir RICHARD WEBSTER has since shown by his reply to a question put on the subject by Mr. PICKERSGILL in the House of Commons, that he intended to stick to his guns, and meant every word he had uttered. Such being the case his statement may now be considered to be a part of the English criminal law.

Under these circumstances it is evident that an attempt to procure abortion, which results in the death of the subject, can never again be reckoned as murder, and accordingly that the verdict of manslaughter found by the jury was the only one open to it, the offence being proved.

That to this, the jury should have thought fit to add a recommendation for mercy, has caused a considerable amount of not unnatural surprise in many quarters. Upon what grounds was the recommendation made? There was no doubt as to the guilt of the accused, he had no blameless past to be urged in extenuation. Far from it, he had actually on a previous occasion been convicted of felony, and it was notorious that for years he had been carrying on the infamous trade of procuring abortion.

That under such circumstances the jury should have thought fit to recommend him for mercy, must depend upon different causes.

Here was a case of the worst possible kind, in which far from there being extenuating circumstances, the accused was an old offender, and yet although the old fashioned charge of murder has been modified and softened down to manslaughter, yet the jury are not satisfied, they go one better, and make a recommendation to mercy.

In doing so, the jury appear to have merely voiced the feeling of the hour, in opposition to the antiquated doctrine of the law; the feeling seems to make plain the obnoxious fact, that the teachings of certain modern would-be-philosophers and supporters of what is generally spoken of as Malthusian doctrine, have not fallen upon barren ground, and that the rank growth has flourished apace.

That the sinfulness and anti-Christian nature of these actions is forgotten, that greater laxity prevails, and that people are demanding for themselves a greater range of individual freedom and to question the right of the law to interfere in matters purely personal to themselves, all point to a degenerate state of society.

In the admirably balanced and justly merited censures of the judge, we are glad to note that there are no signs of pandering to these immoral doctrines and tendencies.

We repeat, that the crime of procuring criminal abortion, is one against which the whole medical profession must set its face, and condemn in the most unqualified terms.

It is sad to see a career like Dr. COLLINS', marked as it was at the outset by the most brilliant promise, brought to a shameful conclusion in the dock and the felon's prison. By what steps he was led to depart from the path of rectitude and to embark upon the downward path of crime, we know not. Pecuniary difficulties probably had their share in his destruction.

If so, he appears to have obtained no relief, for although he is represented as having been earning large sums for years, his conviction found him without any resources. The picture suggested is a dark one. The career of crime brings with it its own Nemesis. The criminal is marked and tracked, some of his secrets are known, and over his head daily hangs the threat of exposure. The felon stalks along, but behind him is the vampire shadow of the blackmailer.

The case is likely to lead to steps being taken to strengthen the position of the General Medical Council. If so, from much evil some good may result.

When convicted of forgery, Dr. COLLINS' name was removed from the *Register*, but the Council that had the power to do this, had no power to deprive him of his university degree of Doctor of Medicine.

We thus have the curious anomaly of a man deprived of his legal status as a medical practitioner. He cannot recover fees in a court of law and he cannot sign a death certificate, yet on the other hand he has a university degree, he is a doctor of medicine and apparently is as free to practice his profession as ever.

It is to be hoped that some means will be found, so that the General Medical Council may have the power, when it strikes a man's name off the *Register*, to once and for all put a stop to his practising medicine as well.

—:—

CIVIL ASSISTANT SURGEONS AND THEIR NEWLY GAZETTED PROSPECTS.

As far back as 1890, the *Record* began its crusade for reforms and improvements in the Local Medical Services. The first instalment of reform was granted to the Military Assistant Surgeons, but it partook of a purely phantom nature, it offered a shadowy enhancement of their status, but left the substantial grievance of their stunted salaries untouched. Now we have the second instalment of reform, if it may by a stretch of imagination be so styled, given to Civil Assistant Surgeons.

The following is the telegraphic summary of the changes which Government has been most graciously and generously pleased to make:—

A Resolution regarding the future position and prospects of Civil Assistant Surgeons is published in the *Gazette of India*. All have been consulted and the cadre of Assistant Surgeons is now divided into four grades, viz., Rs. 100, 150, 200 and 300 a month. They will not in future be placed on unemployed pay, except as a punishment. This change, however, does not affect Madras, Bombay

Burma, or the Central Provinces, where the system is not in force, promotion to the senior grade will be by selection without examination. Nineteen Civil Surgeoncies, viz., five in Madras and Bengal, three in the Punjab and one in Bombay, the North-West Provinces and Burma, are to be filled by Assistant Surgeons and it is hoped to increase this number to 28. The introduction of the new arrangements is subject to the express condition that Municipal and Local Funds shall pay in full measure for the services of Government Assistant Surgeons attached to Municipal and Local Fund Hospitals. Contributions payable to Government by those local bodies for the cost of the services of an Assistant Surgeon, must therefore be raised in provinces where such contributions are calculated with reference to pay only, and do not include the consideration of leave allowances and pensions. The Governments of Madras and Bombay are requested to place Assistant Surgeons on the same footing as those elsewhere, as soon as such steps are practicable.

The Indian Medical Association has made two definite appeals to Government in connection with the grievances of Civil Assistant Surgeons and their scope may be gauged by the annexed statement extracted from the last appeal:—

"I. That Civil Assistant Surgeons be designated Assistant Civil Surgeons, and that their service be merged into the present Uncovenanted Medical Service under the title of the *Indian Civil Medical Service* :—

II. That such Service be graded as follows :—

- (a). Civil Surgeons (as at present graded in the Uncovenanted Medical Service).
- (b). Senior Assistant Civil Surgeons. A new grade, promotion to which will be made after 20 years' service, for special merit.
- (c). First Grade Assistant Civil Surgeon.
- (d). Second Grade " "
- (e). Third Grade " "

3. That the grade salary and pension be arranged as follows :—

Tabular Statement showing Grades, duration of Service, Salary and Pension in each Grade, together with Allowances of the Indian Civil Medical Service.

Grades of I. C. M. S.	Service for Grade.	Salary.	Pension.	Allowance.
1. Civil Surgeon * ..		Rs	Rs.	
2. Senior Assistant Civil Surgeon.	(Special)	800	280	The same as Civil surgeons (I.C.M.S.) when in officiating charge. Grade allowances same as the Subordinate Judicial Service.
3. First Grade Assistant Civil Surgeon	25 years	400	300	
	30 "	550	175	
4. Second ditto.	15 "	250	180	
	10 "	200		
5. Third ditto.	5 "	200		
	150		

* Present Uncovenanted Civil Medical Service, as it stands.

It will be observed with surprise and regret that the Government has behaved most shabbily with this class of medical officers. The *Gazette Resolution* does not touch the question of status, a very sore point with these officers, nor does it make any tangible increase to their salaries

and other allowances. It is quite true that the Government declares that 19 Civil Surgeoncies will now be open to Civil Assistant Surgeons, but we all know that this order will be treated as a dead letter, that with the usual limitations of that red-tape term, "*officiating*," the real work will be ground out of them, but they will get nothing but starvation wages in return, and to crown the delusion which this change implies, these unfortunate pseudo-Civil Surgeons will be transported to some outlandish malaria-stricken holes, where they will rapidly die off like rotten sheep. In short we may state these long suffering servants of the State who asked for bread, have been offered a stone. We shall not pretend to say that we are thankful to the Director-General and others in authority for the niggardness with which they have treated the prayers and entreaties of our Civil Assistant Surgeon brethren, for we have but to state that the pittance offered in this *Gazette Resolution* to a hoary headed medical officer of 30 years' approved service, who is the possessor of a University degree, namely, Rs. 300, is lower than the salary which the Government pays to the most junior Surgeon-Lieutenant of but one day's service, who may chance to be the possessor of those glorious academic qualifications known as the Edinburgh D. Q. and the L. S. A. of London.

This conduct of the Government, harsh and ungenerous as it is, should only urge the members of the local medical profession and the local medical services to more united and determined action in defence of their interests. The medical administration has played its trump card and it exposes a hand that is as ungenerous as it is unjust, and this policy now demands a counter movement that will expose the failures of our rulers in this country, to those who are in real authority in England.

COLLES' FRACTURE OF THE RADIUS.

THE old Bond splint continues to hold first place in the treatment of this fracture in most of the Philadelphia dispensaries. At the Polyclinic Hospital, in Dr. MORTON'S clinic, the splint is used without the leather sides. In this clinic, after complete reduction is made, the arm is placed on the Bond splint, with a pad, made of lint, under the lower end of the upper fragment, and another on top of the lower fragment. The arm is dressed every other day, and the wrist and all the finger-joints are put through their various motions while the bone is held firmly at the seat of fracture. The movements of the hand and fingers are started at the second dressing, that is the next after the primary dressing. The splint is usually removed between the third and the fourth week, and after this simply a muslin bandage is applied for about a week or ten days, during which time the patient comes as often as before, in order that massage may be used. From the beginning the patient is instructed to move the fingers as much as the splint and bandage will permit. Occasionally, when there is a tendency to stiffness of the part, the hot-air oven is used in conjunction with the massage. The rapid return of function under this treatment has been most satisfactory.—*New York Medical Record.*

COMMENTS AND NEWS.

THE USE OF QUININE IN MALARIAL HÆMOGLOBINURIA.

DR. ALBERT WOLBERT of Philadelphia discusses this question in an interesting paper in the "Medical News."

Many physicians in Greece and Italy believe that there is a form of hæmoglobinuria that is caused by quinine, and BASTIANELLI who has recently brought forward the subject quotes TAMARELLI, SPYRIDON, CAPELLIS and PASQUALE-MUSCATI having recorded cases of hæmoglobinuria, occurring during an attack of ague, caused by quinine.

KARAMITZA mentions a case in which hæmoglobinuria could be produced in a student by 5 grain doses of quinine; PLEHN, RICHARDSON and others hold the same opinion.

BASTIANELLI divides the spontaneous hæmoglobinuria into three classes: (1) Those in which the blood contains estivo-autumnal parasites or young hyaline forms, (2) those in which the blood contains only crescentic or oval bodies and pigmented leucocytes, or, (3) those in which the blood examination is entirely negative and the only evidence of there having been an infection is the presence of endothelial perilobular melanosis. Here the attack of hæmoglobinuria does not depend upon the presence of parasites, but begins without apparent cause.

BASTIANELLI finally takes up the quinin hæmoglobinurias, and asserts that (a) It occurs only in individuals in whom a malarial infection has been recently present; (b) the hæmoglobinuric attack is constantly produced every time quinin is administered, whether it be given while the malaria is in progress (TAMARELLI), or when the malarial infection has run its course (MURRI); (c) extremely small doses of quinin are capable of bringing on an attack; (d) quinin hæmoglobinuria has been observed in patients who have already suffered from hæmoglobinuria (MURRI).

The quinin hæmoglobinuria he divides into two forms: (1) That occurring during the paroxysm, or paroxysmal hæmoglobinuria, and (2) postmalarial hæmoglobinuria. In these varieties, through a considerable length of time quinin will produce hæmoglobinuria whenever it is administered. The course to be pursued depends upon the blood examination. If hæmoglobinuria occurs during a malarial paroxysm and parasites are found in the blood, quinin should always be given. If, however, no parasites are found, either as a result of previous administration of quinin or on account of the spontaneous disappearance of the organisms, BASTIANELLI says that quinin should not be given, owing to the possibility that the paroxysm may have been due to its previous administration.

Some interesting cases are quoted in which large doses of quinin have been given without producing hæmoglobinuria. GUBROUNT cites a case in which a lady became deaf, dumb, and blind from taking 10 drams of quinin sulphate within the course of a few days. GUAIOMINI spoke of a case in which a man took 8 drams of quinin and who only suffered from symptoms of depression of the heart and nervous system. BRIQUET records a death following the enormous dose of 55 drams taken within a period of ten days.

LAVERRAN quotes from Baillio, who reports the instance of two soldiers, who, intending to take a purgative, but instead of taking sodium sulphate, by mistake, drank a solution of quinin, so that each received about 5 drams of the salt. Half an hour after taking the medicine the men were seized with cramps in the epigastric region and with vomiting. They presented paleness of the face, dilation of the

pupils, hurried respiration, chilly sensations, a small, irregular, and slow pulse, sometimes hardly perceptible, together with ringing in the ears, and symptoms of syncope. In the case of one, the symptoms gradually disappeared, the other died of heart-failure.

Varieties of Hæmoglobinuria.—Possibly the most logical classification of hæmoglobinuria is made by OSLER, as follows:—(1) Paroxysmal hæmoglobinuria, (2) toxic hæmoglobinuria. The latter includes those due to (a) carbonic acid, (b) chlorate of potash, (c) usphol, (d) carbon dioxide, (e) poisons of infectious fevers such as scarlet fever, yellow fever, typhus fever, and malarial fever.

In the infectious fevers, hæmoglobinuria is caused by the action of toxin on the red corpuscles, causing disintegration and the setting free of hæmoglobin.

DAWSON and DAVIS consider that hæmoglobinuria results from a renal congestion.

In malarial fever, however, it is the spleen and liver and not the kidneys which are chiefly affected.

The morbid anatomy of the kidney in malarial hæmoglobinuria shows a high grade of congestion due to some poison in the system.

It is suggested that malarial hæmoglobinuria is caused by the toxin secreted by the plasmodium.

Amongst American physicians the opinion is generally held that the hæmoglobinuria seen in connection with malaria is not caused by quinin, and that on the other hand quinine is the proper remedy to give in such cases.

Dr. ASHURST stated that he had never seen a case of hæmaturia (hæmoglobinuria) produced by quinine and that he would give quinin for this condition. ANDERSON has seen hæmoglobinuria produced in some cases of malarial fever in which quinin had not been taken, and states that it disappeared upon the administration of this remedy. OSLER says that the condition does not exist in the latitude of Baltimore. TRAYER, also expresses the same opinion.

DOCK (1892). "The treatment of malarial hæmaturia, which also includes hæmoglobinuria, belongs really to the treatment of acute and chronic malarial poisoning. No American physician at the present time has any doubt about the propriety of giving quinin in these cases, so that a consideration of that vexed question is unnecessary."

DAWSON (1896). "The treatment of the different forms of malarial hæmaturia may vary somewhat as to detail, but our first effort should be to bring the patients as rapidly as possible under the influence of quinin in some form."

THE VALUE OF EXPERT TESTIMONY IN MEDICO-LEGAL CASES FROM A MEDICAL STANDPOINT.

DR. A. W. HENCKELL has recently discussed this subject in the *Buffalo Medical Journal*, and has come to the conclusion that something should be done to improve the conditions under which expert medical evidence is given in the United States law courts which by the way seems to be much the same as in England.

According to Dr. HENCKELL there are two ways out of the difficulty. (1) The appointment of a commission by the court; as we believe is done in France. (2) The appointment of a Commission of experts to receive the contentions of the experts of each side, the commission to decide and present their finding as a fact, not subject to review, to the jury.

Dr. HENCKELL prefers the second alternative. Some noteworthy expressions of opinion on the value of expert evidence under the present system are given.

"Lord CAMPBELL stated, in the Tracy Peasage case, that 'skilled witnesses come with such a bias on their minds, to

support the cause in which they embark, that hardly any weight should be given to their evidence.'

"Judge DAVIS, of the supreme court of Maine, stated: 'If there is any kind of testimony that is not only of no value but often worse than that, it is, in my judgment, that of medical experts.'

"In the recent CARLYLE HARRIS trial, the most eminent experts in the State (and out of it) were called to give evidence. These men testified to facts, so called, but they were diametrically opposed to each other. Of what value was this testimony in the obtaining of justice?

"Again, in a recent murder trial in New York, experts were on the stand day after day, for the purpose of deciding the question whether or not the presence of human blood could be positively determined; but here again it was of no value to either side.

"In the BENJAMIN case the medical expert testimony was again brought into ridicule, to such an extent that the jury practically ignored the testimony of all the experts. The reason for this was very apparent, in that the jurors were not familiar with chemistry and its intricate technicalities. It is even asserted that while an eminent expert was giving his testimony a number of jurors fell into temporary somnolency. The fact is the system is to blame and not the experts.

"The mode of examining experts is, usually, in the form of a hypothetical question, put and paid for by the side calling the experts; in other words, the professional man testifies to certain opinions.

The hypothetical question has many objections urged against it. HORNBLLOWER says:

"It is claimed, and with much truth, that the hypothetical question assumes as proved whatever the counsel putting the question has endeavored to prove, and combines insignificant with important circumstances and alleged facts, supported by slight and perhaps worthless testimony, with other facts of which the proof is strong and convincing, while omitting still other facts of equal or greater importance which may be overwhelmingly established by the other side.'

"Expert testimony based upon such one-sided hypothetical questions is almost of necessity favorable to the questioner, and the true remedy is that already adopted by the laws of this State in insanity cases—the appointment of a commission of experts.

The same objections apply to England and we cannot understand how it is that no move has been made for reform in this direction.

TREATMENT OF PELVIC SUPPURATION BY INCISION OF THE POSTERIOR CUL-DE-SAC,

MR. SCHWARTZ, in *La Semaine Médicale*, 13th July 1898, gives his opinion upon this operative procedure, based upon personal operations, in the following terms.

"I will put on one side those cases where a purulent collection is pointing in the vagina and must be opened in that situation, in such circumstances we are all agreed that colpotomy is the proper thing to do, and I will limit my remarks to cases when the pelvic abscess is high up and where there may be some hesitation as to the most favourable way to reach it. In such cases I have adopted the vaginal incision fifteen times. My first case was a young woman with unilateral pelvic suppuration; fluctuation could be felt in the left vaginal cul-de-sac when the abdominal wall was depressed; I punctured it from the vagina. The flow of pus from the wound was accompanied by alarming hæmorrhage which was only restrained with considerable difficulty. This

was an unpleasant accident to the possibility of which I would draw your attention.

"Ten months ago I observed a still graver complication. I was called to see a woman, 40 years of age, whose general condition was most precarious and who had a large pelvic abscess which could be felt in the right vaginal cul-de-sac. I performed lateral colpotomy, washed out and drained the abscess cavity; from this operation she recovered perfectly. Soon afterwards a fresh abscess appeared on the other side. I then proposed laparotomy but it was declined.

"Another surgeon incised, as I had previously done, the right side of the vaginal cul-de-sac: 24 hours afterwards the patient died. Though I have no exact information as to the cause of death, I am nevertheless inclined to attribute it to the colpotomy.

"Finally, quite recently, under the influence of M. MONOD's observations, I attacked by the vaginal method a left unilateral salpingo-ovariitis accompanied by hectic fever. In this way I opened a first collection, above which I found a second and a larger one, having evacuated the pus I was washing it out when suddenly the solution failed to return. I forthwith performed laparotomy, which revealed the fact that above the second sac there was a third, the thin wall of which had been traversed by my canula which had thus penetrated into the peritoneal cavity.

"I then successfully undertook the extirpation of all the diseased parts and drained both through the abdomen and vagina. The patient is now out of danger and making a good recovery. In this case the vaginal incision led to a danger, which the laparotomy alone enabled me to avoid.

"Such are the immediate complications of this operation which appears so simple, now let us consider its future effects. I incised the posterior vaginal cul-de-sac in a woman aged 35 years, for six years she was to all appearances completely cured, but recently a very large abscess reappeared in the same place. I opened and drained it from the iliac fossa as her general condition did not permit of laparotomy. Again she recovered, but who can say that the suppuration may not recur at any time.

"In conclusion, in the limited number of colpotomies that I have done for pelvic suppuration, in three cases I have had immediate complications and in one a subsequent recurrence. In the presence of such results I cannot declare myself in favor of this operation in spite of the remarkable results obtained by M. MONOD."

PRESIDENT PUGH'S VIEWS AND OPINIONS ON THE IMPERIAL ANGLO-INDIAN ASSOCIATION.

Dr. JAMES R. WALLACE reported to the Board of the Anglo-Indian Association that on Friday the 15th July, he had a Conference with Mr. L. P. PUGH, M.A., LL.B. Standing Counsel to Government and President of the Imperial Anglo-Indian Association, at Mr. PUGH's request.

President PUGH after enquiring into the present affairs of the Association, with special reference to the question of the Conference of Delegates from all the Sister-Associations, the agitation concerning the Anglo-Indian Cause at Mussoorie, and the recent correspondence in the *Pioneer*, said (1) He heartily approved of the new name of the Association as the "Imperial Anglo-Indian Association," first, because the term "Imperial" abolished the idea of Provincialism, and embraced all the sister-societies under one head; it gave the idea of union and solidarity, and this is a strong necessity of the times. It abolished the term, "Eurasian," which was objectionable to a large number of the Community, who by the use of this term in the designa-

tion of the Association; were deterred from joining this body. (2) He personally objected to the use of the term "Eurasian" as applied to persons of mixed British or European and Indian descent. He felt it was reasonably objected to by members of the Domiciled British Community, and that if there were no other objection to the use of the term than its objectionableness, this was a sufficient reason for its elimination and disuse. Mr PUGH was of opinion that the desire to compel the Community to continue the use of this appellation on the part of those who had no real sympathy with this section of the British race in India, was a most unworthy one, and the Associations all over the country should make a combined and determined stand to secure their national rights and privileges as members of the British Community and not under a separate name, which would always tend to dissociate persons of mixed race from their kinsmen, and thus give rise to schism and disunion, than which, nothing could be more lamentable and disastrous to the best interests of the Community. (3) Mr. PUGH said with special regard to the effort to create dissent over the expunging of the term "Eurasian" at a recent meeting of the Allahabad Branch of the Anglo-Indian Association, that he thought the meeting of Delegates from all parts of India ought to be held at Allahabad in December. He insisted that because of this very effort to create dissent over the disuse of the term "Eurasian" at Allahabad, the battle ought to be fought out in the centre of opposition. Mr PUGH said if the meeting of delegates was held at Allahabad in December, he himself would endeavor to be present there. (4) With regard to the resolutions passed at a recent meeting of the European residents of Mussoorie, inviting him to be present there at a public meeting to inaugurate a branch of the Imperial Anglo-Indian Association, or requesting Mr. PUGH to depute Dr WALLACE to be present in his stead, he said he much appreciated the honor which the European residents of Mussoorie had offered him, but that as he could not go there, he would have much pleasure in deputing Dr. WALLACE to represent him at the public meeting at Mussoorie, and that when the occasion arrived he would furnish Dr. WALLACE with his credentials for that function. (5) In conclusion Mr. PUGH earnestly hoped that the general vote of the Association on the new Constitution would soon be given, and that the Council would launch out actively and prosperously on its important sphere of social and political work for the well-being of the Domiciled European Community of India.

THE ROYAL COLLEGES ON VACCINATION.

SAYS the *British Medical Journal*—"At the last meeting of the Fellows of the Royal College of Physicians, the following resolution was passed unanimously:

The Royal College of Physicians having learnt that certain charges are likely to be made in the laws relating to vaccination think it their duty to reiterate their conviction that vaccination properly performed and duly repeated is the only known preventive of small-pox, and this opinion they consider to be fully confirmed by the report of the recent Commission.

At a meeting of the Royal College of Surgeons of England, on 2nd August, Sir WILLIAM MAC CORMAC, Bart, President in the chair, the following resolution, adopted by them on 11th May, 1893, and presented to the Royal Commission of Vaccination as expressive of their opinion on the value of vaccination was reaffirmed—namely:

We, the Council of the Royal College of Surgeons of England, desire to put on record at the present time, our opinion of the value of vaccination as a protection against small-pox;

to consider the evidence in favour of its life-saving power to be overwhelming, and we believe, from evidence equally strong, that the dangers incidental to the operation, when properly performed, are infinitesimal. Experience has satisfied us that, even when vaccination fails to afford complete exemption from small-pox, it so modifies the severity of the disease as not only to greatly reduce its mortality, but to lessen the frequency of blindness, disfigurement, and other grave injuries. We should therefore regard as a national calamity any alteration in the law which now makes vaccination compulsory. We are moreover firmly convinced that vaccination is an additional safeguard, and should be universally practised. We would add that we believe that the instructions of the Local Government Board for public vaccinators are well designed to secure the greatest efficiency in vaccination and to avoid the liability to risks from operation. These are weighty declarations, which should have all the more force in that they emanate from bodies better entitled to speak with authority on the subject than any other. It is perhaps the only question in the whole domain of medicine in regard to which the profession are practically unanimous.

THE OPIUM TRAFFIC IN INDIA.

THE Anti-Opium Society in England continues its righteous war against State traffic in Opium, and every day gives encouraging evidence of its approaching victory. The curse will soon be removed, for the Government of India cannot hold out much longer in its greedy grasp of this iniquitous enterprise.

Under the heading "Words of cheer," the society has the following remarks:—

The resolution adopted at our last Annual Meeting, by which a large number of friends of the Anti-Opium cause in foreign lands were appointed corresponding members of the Society, has brought us many encouraging responses from those whom we have thus sought to identify more closely and permanently with the movement. These friends have heartily reciprocated our feelings towards them. One of the most interesting of these letters is that received from Dr. MOOKERJEE, of Calcutta, whose admirable evidence before the Opium Commission in that city will be remembered by many of our readers. It is due both to them and to the writer to reproduce it here:—

98, Mookerjee Baboo's Street, Calcutta, 14th Apr 11, 1898.

My Dear Sir,—I beg to acknowledge receipt of your favour of the 12th March, in which you intimate a resolution of your Society appointing me a corresponding member of the Executive Committee of your Society for India. I am thankful for the kindly appreciation thus evinced of my humble efforts to support the cause of your excellent society, which aims at the suppression of the iniquitous traffic in Opium in my country.

I most gladly accept the honour you offer me, and I can only add that I shall bear the burden it entails with loyalty to the highest interest of my countrymen, and with a due regard to the more and noble efforts of our British friends, who deserve the prayerful gratitude of all nations for their glorious attitude in the defence of national righteousness. I would reiterate my earnest pleadings, which I ventured to urge upon the Royal Opium Commission, that your countrymen adopt measures to suppress the awful strides of King Alcohol in India, a demon whose withering touch is destroying the lives, devastating the homes, and blighting and blasting the temporal and eternal prospects of my countrymen.

With kind regards and hearty good wishes. I am, yours sincerely,
LAL MADHUB MOOKERJEE, Rai Bahadur,
L.M.S., F.G.U. President, Calcutta Medical School;
President, Indian Medical Association, Honorary Presidency Magistrate.

CLIMATIC TREATMENT.

THE following is an extract from an "Address on circumstances which influence the effectiveness of Climatic Treatment" delivered before the British Balneological and Climatological Society, June 1896, by Dr. G. V. POORE.

"It is not only necessary that a doctor attending a patient to a health resort should have a personal acquaintance with the main climatic conditions of the country or district, but it is equally necessary that the patient should have the benefit of local knowledge as well. The word "climate" is generally used in a wide sense, but it is very necessary to remember that climates are often extremely localised. Go to the south side of a garden wall running east and west, and bask in the brightness and warmth, feast on the peaches ripe and ruddy, and listen to the hum of insects gliding in the sunbeams. Then go to the north side—damp, all in chilling shadow; content yourself with a few hard pears or acid cherries, escape off the damp moss growing in the moat, and sniff the fusty smell arising from the dank snow-balls. Can any contrast be greater? And yet these climates are only separated by a space of some six inches. In houses there are rooms with different climates; in towns there are streets with different climates; and in districts, as we all know, it makes all the difference whether the house is on the north or south side of a hill; whether it is in a hollow where the air stagnates and the mists are only reached by the sun when the day is far advanced; or whether it is fairly open to the purifying influences of the wind and sun."

NEW R.A.M.C. AND I.M.S. SURGEONS.

The following lists give the positions of the young officers of the Royal Army Medical Corps and Indian Medical Service when leaving Netley, with the combined marks of the Netley and London examinations, the final positions on the list being determined by the results of both examinations, while the prizes are awarded for marks gained in the special subjects taught at the school.

THE VACCINATION BILL.

COMPULSORY vaccination has at length come to an end in England. Owing to the sturdy opposition of a minority and unwilling to face a severe fight in the House of Commons, Mr. BALFOUR has given way on the point of compulsion; and Mr. CHAPLIN much against his will, or at any rate in the

MEDICAL RECORD.

[SEPT. 1, 1899]

teeth of all his former protestations, has been obliged to add the following clause to the Bill for which he is responsible:

"No parent or other person shall be liable to any penalty under Section 29 or Section 31 of the Vaccination Act of 1907, if within four months from the birth of the child he satisfies two justices in petty sessions that he conscientiously believes that vaccination would be prejudicial to the health of the child, and within seven days thereafter delivers to the vaccination officer for the district a certificate by justices of such conscientious objection."

It is well known that compulsory vaccination has been for years resisted in parts of England, in the town of Leicester with 200,000 inhabitants, yet in this town for five years there was not a single death from small pox.

The case for vaccination is however considered to be too well proved by all those who have studied the subject, to be shaken by exceptions like this; and we fancy that although no longer compulsory it will still be resorted to almost as largely as ever by the better educated section of the population. Amongst the others, many will probably find it easier to get their children vaccinated than to comply with the above clause, so that we do not fancy its consequences will be very marked.

ANGLO-INDIAN VERSUS BRITISH PLAGUE DOCTORS AND NURSES.

In drawing the attention of Government to the dismissal of Anglo-Indian Nurses from the Manipalka Plague Hospital, the Board of the Anglo-Indian Association have adopted the following Resolution:—

Resolved.—That the Board of the Anglo-Indian Association have viewed with considerable anxiety and alarm the policy of the Bengal Government, in importing from England, medical men and nurses for plague duty in this Presidency, when local talent of suitable quality was so largely available.

This policy has resulted in a decided hardship to medical men and nurses in this country, who are in every way qualified for such duties, and the Board feel that it has just ground to complain against the action of the Government. They further desire to point out that such a policy, while inflicting a grievous wrong on local talent by placing an unmerited brand of inferiority upon medical men and women educated in this country, not only stamps the system of Government medical education in India, with the stigma of incompetency, but renders still more tangible and real, the disabilities under which the Domiciled European Community of India labor under the present system of Government.

If the plan be retained by Government that it was necessary to import English medical and nursing labor because of its superiority to locally-trained labor, the Board feel that this plea only still more strongly emphasizes the position which it maintains, that State medical education in India is an admitted failure and demands reform. The Board from a public standpoint, desires most emphatically to state that the importation of British medical and nursing labor for plague duties was absolutely unnecessary, and the utilization of our own talent, in view of the fact that the men and women so employed were without experience of tropical diseases, of the languages, customs and social and religious prejudices of the country, was a serious mistake, involving, as it does, the unnecessary expenditure of large sums of money in the passage to and fro of the persons so engaged by the India Office, the payment of large salaries, such as in no case would be paid to locally trained labor, and the continued expenditure on such unsupported agencies, whether employed or unemployed.

Resolved.—That the above resolution be forwarded to the Bengal Government, the Plague Commission and the Government of India with a covering letter.

ANTI-PLAGUE INOCULATIONS IN CALCUTTA.

The Biley-Plague Commission and the Bengal Government are probably secretly congratulating themselves that they did not, as they at first intended, cease the people of Calcutta into accepting the abominations of HARKIN's plague inoculation. They must now feel like thanking those who in the Municipal Council and in the medical press warned them against so calamitous and tyrannical a policy. The "conscience clause" just admitted by Parliament into the Vaccination Act, which the medical world believed had its foundations immovably fixed on solid rock, must be a very severe shock to HARKIN and his crew, as also to a philanthropically disposed, but utterly misguided Government. Fortunately for the evil results that may come to those who are inoculated with plague virus—results which no one can authoritatively say will not come—the HARKIN fad is dying out in Calcutta, as is also the Biley-Plague. It is a remarkable fact that most faddists experiment on others and do not trust the vaunted virtues of their own theories on their own persons. It was said that the plague staff of Calcutta intended to set the example to a bewildered and ignorant populace, of paving the way to the acceptance of the filthy planting system, by undergoing this blood poisoning operation themselves. Up to the present however the plague staff have done exactly as all other faddists do, they have shirked the operation, and show by this conduct that they have no more faith in HARKIN, than they have in the moon.

ANGLO-INDIAN VERSUS BRITISH NURSES. HOW THE MONEY GOES.

A FEW months ago, two Anglo Indian nurses were employed in the Manicktollah Plague Hospital on salaries of 1 rupee a month and free quarters in the hospital.

They were rendering excellent service and it is official recorded that they were competent, skilful and attentive. Suddenly two ladies from England appeared on the scene with passports from the Secretary of State for India, for employment as plague nurses.

They went over to the hospital, saw the quarters occupied by the locally trained nurses, and they were so utterly disgusted, that they refused to occupy such quarters. They were immediately escorted to the Great Eastern Hotel the best and most expensive hotel in Calcutta.

On the plea that there was not enough work for them, the Anglo-Indian nurses were discharged from their appointments, really with the object of being displaced by a superfine British material just imported. Mark the sequel. These two sprightly lady nurses, with all the bloom of the English complexions, were hastily sent on to Darjeelings summer there, as it was feared they might lose their health and their lovely complexions. These nurses are on an "employed list" and yet are utterly unemployed. The Municipal exchequer of Calcutta has to pay them 800 rupees a month for doing nothing, and these will probably be contingent bill for other necessary and unavoidable expenses, which the Municipal Council must pay with a murmur and without question, for under the Plague Infection Diseases Act, the President of the Plague Commission,—Financier BILEY—may order any extravagance he pleases without reference to the Municipality, and at any cost body must simply grin and bear his behests. It is government with a vengeance.

MORE PLAGUE DISCOVERIES.

A CURIOUS discovery has been made, says the Pioneer, by Mr. HARKIN, who explains one of the difficulties met with in the attempt to eradicate plague. Mr. HARKIN has carried out a series of experiments, with special reference to dis-

infection against plague. While in Hardwar, he discovered that it is extremely difficult to disinfect an ordinary mud and cow-dung floor instead of eradicating them. The ordinary solutions, sublimate and carbolic acid, were found to lead to an apparent increase in the number of microbes present. The failure of the sublimate solution was found to be due to the destruction of the sublimate by alkaline substances in the floor. The reason for the failure of the carbolic acid, for some time puzzled the investigators, but experiments carried out by Mr. HARKIN and Lieutenant Stepanoff, B.A., ultimately proved that the failure was due to the cow-dung, not to the mud. The latter was easily disinfected by means of 1 per cent of carbolic acid. Further, it was found that the microbes, bred in the cow-dung, do not possess any special resisting power, for they were easily killed when separated from the dung. The resistance to disinfection depends on the presence of some substance in the cow-dung, protecting the microbes from the action of these disinfectants. What that substance is, does not seem to have been discovered, but we presume Mr. HARKIN will not relax his efforts, until he has found out the nature of the substance and the means of neutralising it. To leave it undiscovered, would be to grant immunity to one of the most fertile sources of plague propagation.

REMOVAL OF STREET REFUSE.

At a recent meeting of the General Committee of the Calcutta Corporation, a suggestion was submitted for consideration by Dr. COOK, Health Officer, that it was not desirable at present to introduce an afternoon service for the removal of refuse. Amongst other objections, he thought that in certain parts of the town, where afternoon service was most needed, such as Burra Bazaar, it would be practically impossible on account of the congestion of traffic. The increased cost would be Rs 1,03,095, against Rs. 42,078 in the Budget estimate submitted. This did not include a night-train service to the Salt Water Lakes and unloading wagons by artificial lights, so that they might return empty for the morning service. Unremoved refuse was no doubt unsightly and offensive, but he doubted whether it was any appreciable danger to health unless not removed for more than twenty four hours. At present, he was of opinion that the work of removal began too early, men did not work well in the dark, and supervision was difficult if not impossible. Dr. COOK recommended mustering at 5.30 A.M., and working till 11.30 A.M. He was also of opinion that the pay of the coolies should be increased.

A STORY OF JAMES SYME.

DR. MALCOLM MORRIS writes:—"A story of Syme, which I heard many years ago, made a deep impression on me as showing at once the honesty of the man and his ready tact. He was fond of impressing on his pupils the propriety of always putting a grooved needle into a breast before proceeding to remove it. On one occasion, before operating on a woman with a breast of stony hardness, he repeated his customary warning, adding that although in the case before them there could be no doubt that the disease was scirrhus, he would yet, by way of showing an example of obedience to a salutary precept, take the precaution which he wished them to employ in similar cases. Accordingly, he plunged the needle into the patient's breast, with the result that a gush of pus took place. Instead of being disconcerted Syme turned to the class and with a little bow, said "There, gentlemen, that points in a manner which I didn't expect the moral I wish to impress upon you!" So struck were the men by the utter freedom from humbug thus displayed, that they cheered the teacher who had turned his own mistake into a profitable lesson for them. Medical students are the most ruthless of critics, and only a truly great man could have done this."

AN EXTRAORDINARY HEALTH APPOINTMENT IN CALCUTTA.

A LITTLE while ago, our very worthy Health Officer—Dr. NEILD COOK—was, under the superior guidance of the Bengal Plague Commission, supervised of course by the infallible sanitary Mahatma who presides over that august but mysterious body, ordered to give over the bulk of his duties to Surgeon-Major W. B. BANNERMAN, M.D., EDIN. I. M. S. of Madras. Dr. COOK's salary is Rs 1800. Dr. BANNERMAN was given Rs 1700! Dr. COOK is a sanitary expert of experience, with a sanitary degree, Dr. BANNERMAN has no sanitary diploma; yet the latter gentleman because he had the hall-mark of the I. M. S. after his name, was made to supersede Dr. COOK and the taxpayers were compelled to pay Rs 1700 per mensem for this fancy article by command of the great Hisley Company. Now that Dr. BANNERMAN has got disgusted of Calcutta and wishes to go away to his balmy Southern domain, we find the Bengal Plague Commission guilty of another act which indicates a spell of mental aberration, inasmuch as a young doctor, absolutely devoid of sanitary experience, possessing no sanitary diploma, a gentleman who has had only a few years of practice as a tea planters' doctor in Wynnad (Madras) has been appointed to succeed Dr. BANNERMAN, and thus a grave injustice has again been inflicted on Dr. NEILD COOK as well as upon the public. Dr. PATTIFER, the successor of Dr. BANNERMAN, is M.B., M.R.C.S., and entered the profession in 1884, while Dr. COOK is not only four years PATTIFER's senior, but has all the advantage of special qualification in sanitary science and a few years of practical hygienic experience in India. We cannot congratulate the Bengal Plague Commission on either the wisdom or the justice of its selection, and we feel bound to say that the Municipal Sanitary Council is being very badly driven by Messrs. HISLEY, HENDLEY & Co both as regards its capacity for good work and the extravagance of its upkeep.

THE HÆMATOZOA OF GOITRE.

THE following statement was made at the meeting of the Academy of Science on the 4th July, by M. E. GRASSET.

Our attention having been drawn to certain facts which appear to argue in favour of the infectious nature of goitre, we have been led to seek for the pathogenic agent of this disease.

In old cases an examination of the blood showed nothing abnormal, but in eight persons whose goitres were said to have only existed for 10 or 15 days, we succeeded in demonstrating the presence of parasitic agents in the blood which was taken from the finger with all the usual precautions.

These agents recall the appearance of the hæmatosoa of malaria, described by M. LAVERAN, they differ however in the colour of the pigment which is brick red and by the absence of crescentic bodies. It is necessary to remark that none of our cases had ever suffered from malarial affections of any kind.

THE DEATH OF DR. K. N. BAHADHURJI

WE deeply regret to record the unexpected and untimely death of one of India's most brilliant and talented medical men. In the demise of Dr. K. N. BAHADHURJI of Bombay, on the 15th August, the local profession loses a precious ornament, for our departed friend was a great scholar, an honorable man and a zealous patriot. He held the degree of M.D. of the London University and was a scientist of a very high order. In him, original research and bacteriology have lost an ambitious and energetic devotee, while the cause of medical reform has been suddenly shorn of one of its warmest advocates and most

zealous supporters. To Dr. BAHADHURJI, the local medical profession owes a debt of gratitude, the full measure of which, cannot now be appreciated, but in years to come, the nation of Dr. BAHADHURJI's earnest warm hearted labors for the advancement of medical reform in India, will, it is hoped, and many who will then be prepared to honor his memory for the good he has done. Dr. BAHADHURJI had gained a very honored position in public affairs, and in the esteem of his professional brethren all over India.

THE "INDIAN MEDICAL GAZETTE" AND MEDICAL REFORM.

WE are glad to note that in its last issue, the *Indian Medical Gazette* has awoken to the necessity for reform in Medical Education in India, and that it has taken up and championed one of the most important points that we have been hammering away at for some time past. This is an encouraging and welcome sign.

That the *Indian Medical Gazette* should at the same time so veil its sympathies in this direction, by making the most of some minor differences, is of course only to be expected in a strictly official journal, which has for years accustomed itself to view everything through rose coloured spectacles; and whose existence might be seriously jeopardised by greater latitude of thought, or freedom of speech.

With a journal so situated we can sympathise and make every allowance, but at the same time we rejoice to find that a light of truth is at last beginning to break through the clouds of officialdom.

THE TREATMENT OF STYES.

A. T. W. VERY kindly sends the following reply to a query in our last number —

LEUCIOUS inquires for treatment of styes—Internally a purgative aperient. Locally, a paste made of the seeds of the fruit of the Data.

Crush the date stones to a fine powder on a clean stone with a curry-stone, mixed with just enough water to keep the seed-powder wet, collect this in a gallipot, keep it closed, and apply carefully with the finger to both eyelids, eyes being shut, just before getting into bed at night. Next morning wash off the paste, and renew it if you can stay at home, avoid light, and remain in a dark room. If you cannot spare time for this, put a bandage over the eyes affected while you are at work, and renew the application at night on going to bed. This mild astringent usually cures the stye in two or three days.

It is a favourite remedy in native families—Mind the paste does not get into the eye.

PLAGUE IN BOMBAY.

THERE is unfortunately no further falling off in the number of deaths from plague in Bombay; they are at present ranging with marked regularity between 60 and 70 a week. This compares badly with the lowest death-rates during the lull last year, and is causing considerable anxiety. The following are the figures for the corresponding weeks in each year,

Week ending	1st June ...	84			
"	8th " ...	34	7th June ...	44	
"	15th " ...	36	14th " ...	36	
"	22nd " ...	19	21st " ...	15	
"	29th " ...	11	28th " ...	53	
"	6th July ...	7	5th July ...	38	
"	13th " ...	4	12th " ...	55	
"	20th " ...	9	19th " ...	68	
"	27th " ...	14	26th " ...	40	
"	3rd Aug. ...	18	2nd Aug. ...	62	

A MEDICAL HISTORY OF THE FRONTIER WAR.

It is understood that Surgeon-Lieutenant-Colonel BEAVER, the Secretary to the Principal Medical Officer, Her Majesty's Forces, India, has got an extension of three months for tenure of that appointment in order to complete the medical and surgical history of the late Frontier operations. Comparatively little has been published of the working of the medical department in the field this year, but we have heard of many brilliant results in the application of antiseptic surgery to the wounded on the field. The same is true of the recent battle of Atbara (the Sudan). It is said that in many cases the antiseptic "first field dressings" applied to the wounds on the field battle proved so satisfactory that they did not need change nor renewal till the soldiers arrived in England many weeks after. Twenty years ago such a result would have been regarded as simply impossible.

THE MICROBE FAD.

We take the following from the *Sentary Bulletin* —
 "They say there's 'mikrobes' all around, huntin' for thee
 "There's nuthin' pure tew eat or drink and no safe place
 "There's 'miasmy' in the dew-fall and 'malaria' in the sun,
 "Tain' safe to be out doors at noon or when the day is done.
 "There's 'bactery' in the water and 'tricheeny' in the
 'Ameeby' in the atmosphere, 'calory' in the heat;
 There's 'corpussels and pigments' in the human bein's blood,
 And every other kind of thing existin' sense the flood.
 "Terbacker's full of 'nickerteen' whatever that may be,
 And your throat will all get puckered with the 'cannin' if
 The butter's 'oily-margareen, it never saw a cow,
 And things is gettin' wus and wus from what they be juss
 now,
 "The butter's 'oily-margareen, it never saw a cow,
 And things is gettin' wus and wus from what they be juss
 now,
 "The butter's 'oily-margareen, it never saw a cow,
 And things is gettin' wus and wus from what they be juss
 now,
 "The butter's 'oily-margareen, it never saw a cow,
 And things is gettin' wus and wus from what they be juss
 now,"

QUARTERLY REPORT OF THE PENANG BRANCH OF THE INDIAN MEDICAL ASSOCIATION.

NINE meetings were held during the quarter ending 30th June, 1898.

There was a good attendance of Penang members.

The subjects taken up for discussion were:—Abortion and miscarriage, Soil; Functional Diseases of the Brain; Hernia; Air; Disease of the Heart; Diseases of the bladder and urethra; Retention of Placenta and Post Partum Hemorrhage; Bright's Disease; Mechanism of Labor.

A proposal to exchange Medical journals with Singapore members was carried.

Exhibits.—A two months' ovum with membranes intact by Mr. CARNEGIE

J. FAIRLEY CARNEGIE, Member of Committee for Penang

THE I. M. S. AND MILITARY TITLES.

SINCE our editorial on this subject has been through the press, Reuter telegraphs from London that in connection with the new military titles and designation of the I. M. S. will also become the recipients of pure military titles as General, Colonel, Major and so forth, but the designation of their department will remain unchanged. They will not, as they certainly could not, be formed into Royal Corps. But the questions will arise; You are a Colonel? Yes! In what corps? No corps! Then how can you be a Colonel?

The grant of military titles to these quasi-civil officers makes their employment on civil duty all the more glaringly anomalous, and renders the claim for a complete separation of the military from the civil branches of the Indian Medical Service, a paramount and imperative necessity.

AN ANALYST ANALYSED.

Indian Engineering says:—"Professor HANKIN's analysis of the samples of Ootacamund water sent to him, has been referred to the Acting Sanitary Commissioner at Madras for opinion. It is considered by Government that the reservation clause in the analysis makes it very indeterminate. However, as it requires a scientific man to decide what the value of this reservation is, the matter has been referred as above stated. The Government now awaits Surgeon-General THOMSON's Report on the sanitary condition of Ootacamund, as well as his opinion on Dr. HANKIN's analysis." HANKIN is neither a Professor nor a Doctor, but a very humble individual holding an invidious appointment.

VACCINATION FOR TYPHOID.

THE following District Order has been published at Lucknow:—"Commanding Officers are requested to furnish the Sanitary Officer, Oudh District, Lucknow, the names of any officers or men who wish to be vaccinated for typhoid enteric fever. From recent observations it is believed the vaccination will afford protection from the disease for life." This is a satisfactory indication of professional life; but if the results of recent observations prove so much, why the scope and character of the experiment should be made public. The grounds of faith in an operation, which is believed to afford protection against typhoid for life, cannot be too soon or too widely published.

A LITTLE WAR ANECDOTE.

LAYS the *Philadelphia Medical Journal*:—"A junior officer was assisting a transport in disembarking his troops, and covered that one of the men was so ill that he could not stand. The officer took the sick man to a steamer flying Red Cross flag; but the authorities refused to receive him, as he had no ticket—was not officially ill. The officer now, the man aboard and refused to take him away. "We can't have any guns aboard here," cried out the Red Cross sanitary surgeon, and proudly heaved the sick man's gun ammunition-belt overboard!

SHORT ITEMS AND PERSONALITIES.

Mr. T. H. W. Idris, L.O.C., in the *Chemist and Druggist*, are three maxims, unimpeachable in their quality. He says my opinion, success in business is dependent on three things:—(1) Spend less than you earn. (2) Take care that your business is done in the best and most honest manner in every detail. (3) Let your principal desire be to work your business well, and in such a way as to be beneficial to yourself and those who are dependent on you, or to those who we claims upon you, and to the community.

The death of Dr. Gobind Chunder Dass, of Ahirtila, occurred on the 2nd August. The deceased was in his seventy-fifth year. Born in May 1829, he was admitted to the Medical College at eighteen years, and, having passed out of it in 1848, entered Government service as an Assistant Surgeon. He left the service a few days before the Mutiny, came back to Calcutta, and lived at Ahirtila, where he was born. During the last twenty-four years of his life he was totally blind. He was known as a very philanthropic man.

Surgeon-Captain C. B. Stevens, M.D., London, F.R.C.S., is another of our distinguished Anglo-Indians. To developing obstetric abilities he lays just claim to being a ballet, the characteristic features of his exquisite singing being a thoroughly clear and distinct enunciation and a very well disguised effeminate falsetto.

Assistant Surgeon-Oberst Lal Bahadur, F.R.S.E., Chemical Examiner to Government and Assistant Professor of Chemistry, Medical College, Calcutta, is appointed to be in charge, in addition to his own duties, of the current duties of the office of Chemical Examiner to Government and Professor of Chemistry, Medical College, Calcutta, during the absence, on leave, of Surgeon-Major L. A. Weddell, or until further orders.

The Royal Society, recognising the importance of the scientific study of the causes of malaria and the mode of distribution, and having regard especially to the researches of Surgeon-Major Ross, of the Indian Medical Service, into the relation of the mosquito to the malarial parasite, have appointed a small Committee to consider the subject, and to confer with a Committee appointed by the Colonial Office.

The death occurred at Cheltenham, on 24th July, of Surgeon-General W. Johnstone, late of the Madras Army, who served with Sir Colin Campbell throughout the Chinese War, and was present during his engagements, receiving the medal and clasp for bravery and distinguished services. For many years he was Deputy Inspector of Hospitals in the Madras Presidency. He retired from active service in 1878.

It may be of interest to learn that between the 24th July and 10th August, 23,783 rats, 8,780 bandicoots, and 6,480 mice were slaughtered, the cost being paid for by the Madras Municipality at the rate of six ples per rat or bandicoot, and three ples per mouse. As rodents are supposed to convey plague, the slaughter is being continued and the dead rats are being cremated.

Surgeon-Captain J. C. S. Vaughan, M.B., C.M. Edinburgh is one of the distinguished Anglo-Indian ex-pupils of St. Paul's, Darjiling. He married Miss Sinclair of Darjiling a few weeks ago, and the event was a day of rejoicing at St. Paul's, for the boys had a holiday in honor of his marriage.

Surgeon-Captain B. Byrd, Resident Medical Officer, Civil College Hospital, Calcutta, is appointed to act in addition to his own duties, as Professor of Physiology in the Hospital. Surgeon-Captain F. C. Clarkson is appointed to act as Civil Surgeon of Nadia, vice Surgeon-Captain B. H. Deane on deputation.

A summons was granted by the Chief Magistrate, Bombay, against Dr. Dias, in charge of the hospital, for liberating a man suffering from plague, and thereby doing a rash and negligent act, likely to spread infection. The information was laid by Lieutenant Judge, District Officer.

At a meeting of the Fellows of the Royal College of Physicians in Ireland, held on the 28rd ult., it was unanimously resolved that the Honorary Fellowship should be conferred on Sir Charles Cameron, the head of the Public Health Department of the City of Dublin.

The Master in Surgery, Gay De Cebuliac, who flourished between 1800 and 1870, was the author of the first surgical treatise of importance after the Middle Ages, a work that had full sway for two centuries. He grouped together a few precepts for his own and his pupils' guidance.

It is gratifying to observe that a young Indian, Mr. S. C. Mahalanabish, B.Sc., F.R.M.S., F.R.S.E., has been appointed Professor of Physiology in the University College, Cardiff, for a year, in place of the distinguished Physiologist, Professor Huxcroft, on leave.

Doctors having a good time in Madras. Madras all General Military Practitioners—Colonels, Majors, Captains—have ordered new scarlet sashes for their gaudy old-fashioned title "Dr." is too common, even "Colonel" is too ordinary. A real live Major or "Colonel" is now to be tolerated.

L. Simonds, French specialist, who arrived in Bombay in May, with the plague serum, after successful treatment of cases at Karachi, left Bombay on Tuesday for Dacca, where he will remain until next month. He will proceed to Saigon in Indo-China.

It is stated that over one thousand sets of individual communion cups were sold to about three hundred churches in this country during 1897. Each service consists of ten and forty small cups or glasses, holding each about one ounce.

Charles Banks, M.D., C.M. Glas. D.P.S. & F.P.S., has not been stated in our last number begun private practice in Calcutta. His official position, as Medical Inspector of Hospitals and Health Officer of the Port of Calcutta, deprives him of this official privilege.

General Hendley, M.D., C.I.E., I.M.S. Inspector-General of Civil Hospitals has gone on tour. It is stated that he will do some snipe shooting. Who will dare to say after that the Military spirit is not alive in the Civil side of I.M.S.

Surgeon-Captain W. H. Pilgrim M.B., L.B.A. London D.S. England, Superintendent of the Presidency General Hospital does not engage in general medical practice as this is forbidden by Government. He is allowed consultation work.

The Government of Mysore has sanctioned the proposal to send Mr. Palpu, Assistant Surgeon, to the Continent for the purpose of making a special study of vaccination. On his return the Government proposes to erect a lymph-manufactory at Mysore.

Miss Elizabeth Phillips, House Surgeon of Cama Hospital, Bombay, died recently from plague after an illness of about two weeks. She was about 25 years of age. After graduating at Calcutta, she joined the Cama Hospital in December, 1896.

The University of Aberdeen conferred the honorary degree of LL.D. on Dr. William Osler, Professor of Medicine at Johns Hopkins University, Baltimore, U.S.A., at the graduation ceremony, on 21st July.

Dr. Ghiesbreght, the senior physician of St. Mary's Hospital, London, has presented the medical school attached to the hospital with the sum of £500 to found a gold medal in clinical medicine.

Military Assistant Surgeon W. Clarke, Officiating Assistant to the Surgeon Superintendent, Presidency General Hospital, Calcutta, is appointed to act as House Surgeon to the Howrah General Hospital.

Surgeon-Lieutenant-Colonels T. J. H. Wilkins and P. H. Benson have been selected to fill the next vacancies in the rank of Brigade-Surgeon-Lieutenant-Colonel on the Madras Establishment.

A late government examination of the eyes of 8,125 children in twenty-five elementary schools of London is said to have shown that scarcely forty per cent. were possessed of normal vision in both eyes.

The Indian Medical Service of Bengal being rather short-handed at present, the Government of India have had to be asked to make arrangements to fill existing vacancies. The latest of such appointments filled has been one at Durrbanja.

The Madras Government has decided to construct a deep level canal from the south-west corner of the harbour to the Cooum, and plans are now being prepared. The canal will probably be connected with the proposed boat basin or docks.

Major Tomkins, L.S.A. Lond., I. M. S. Civil Surg. Bhamburda, has just ordered a handsome *vest* outfit Ranken's. He will make an inspection of his uniforms.

Lord Wolsey has issued a Memorandum to the enjoining temperance and purity of the troops, and the officers to supervise and advise morality on the their men.

After a very extensive experience with hypnotic the neurologist Charcot, concluded that not more than hundred thousand sick persons would be apt to derive therefrom.

A prominent American actress died recently from indefinite malady, and it is now asserted that her due to a too liberal use of an obesity-cure. She was habit of swallowing the nostrum in very liberal quantities.

Assistant Surgeon W. C. McMillan, doing duty Garrison Dispensary, Fort William, has been ordered sent to Jask, Persian Gulf, as soon as possible.

Military Assistant Surgeon G. T. Milschem, attach Howrah General Hospital, is appointed to act as Surgeon to the Mitford Hospital, Decca.

Miss Grace F. Pereira, M.D., L.S.A. has rejoined the Fund Service on her return from England, and has been appointed to Okhtagong.

We regret to learn that several children are dying typhoid at Mummoorie. The station has hitherto been this season.

The Bombay Corporation have resolved to advance for a loan of forty-nine lakhs, of which two are to cover plague expenditure.

"Surgery should be as the handmaid of medicine, planting her mistress nor yet usurping her rights, but assisting her to maintain them."

Tropical-heat being experienced in London, several are recorded from excessive heat and innumerable sunstroke are reported.

Surgeon-Captain C. Donovan is to take up the preparatory to the Surgeon-General, Madras, made vacant by Surgeon-Captain Elliot's transfer to Coonoor.

Dr. Rave, Inspector-General of Hospitals, Punjab India for England on furlough, preparatory to his resignation. Dr. Franklin will succeed Dr. Rave.

Dr. H. O. Garth, M.B., Ch.M., Edinburgh, has joined Dr. Greenhill, L.R.C.P. Edinburgh, M.R.C.S., England, in practice in Camac Street.

Mr. George Robertson, M.R.C.S., of Chitral Fane, has decided not to return to India, has joined the Council of the Indian Section of the Society of Arts.

Dr. S. O. Moses, L.R.C.P., Edinburgh, has resumed, at 4, Wood Street.

Dr. Zama Feldstein, M.D. has begun work at Dharamatala Street.

Acetylene, when liquid or when subject to pressure greater than one atmosphere, shall be deemed an explosive.

We regret to announce the death of Major G. S. S. R. A. M. O. at Marree, two weeks ago.

The Medical Register and Directory of the Indian Empire is now ready and is being sent to all registered subscribers. We should be lost to secure copies.

Current Medical Literature.

MEDICINE.

Treatment of Delirium Tremens.

LOOKING upon Delirium tremens as a toxic condition in which the nerve centres are seriously disturbed by the excessive use of alcohol, Dr. F. D. CHARTERIS insists on sequestration with full control of the patient and complete withdrawal of alcohol as the first essentials in the treatment. This should be followed up daily with hot baths and free massage. As the delirious period cannot be cut short by narcotics or hypnotics, they should not be used; but the prime object being the elimination through the skin, bowels and kidneys of the toxic poisons which are present, the free bathing should be supplemented with calomel and saline catharsis, which should at first be free, irrespective of all weakness and apparent prostration which may follow. The patient kicks against the first bath; but once compelled to submit to it he never objects to its repetition and sleep usually follows within 24 to 36 hours after free catharsis and bathing, while the insomnia and muscular agitations are limited and will end in sleep and rest after 4 or 5 days, though the hallucinations may continue for a week or two with lucid intervals which constantly increase in length. Where bathing is impracticable, diaphoretic drugs of which ipecac is the best, should be given; but neither tonics nor stimulants are to be exhibited until after the complete subsidence of the delirium and the full establishment of the period of sleep and exhaustion when strychnine nitrate grs $\frac{1}{4}$ may be given 4 times daily, or infusion chin-chona every 8 or 4 hours. Chloral, digitalis, opium and the long list of ammonia combinations and coal tar preparations are dangerous. No food should be given until free action of all the eliminatory organs is established, when hot and easily assimilable liquid foods are required. As forcible restraint is in most cases dangerous to the patient, let him be kept under close observation, but permit him the fullest exercise compatible with his safety and his surroundings.—*Med News*

Influence of the Mind upon the Body.

Is much greater than the majority of the medical world are just now proposed to admit, though phycians have long used some form of Mind-cure, but often without fully understanding whether the drug employed, or the patient's will power, or the degree of faith imposed in the medical adviser, effected the cure. Be these as they may, Dr. I. S. STONE of Washington D. C., points out that CHARTERIS, perhaps more than any other modern physician, belongs the credit of having rescued the practice of mental therapeutics from the deep sea of fraud and imposition to which it was consigned by an honest if not a discriminating profession, who forgot that in every community are to be found a very large number of nervo sanguine patients, who may take real or pretended drugs with equally good effect, and that while many nervous women demand some application of the mind cure in every variety of disease, just as they manifest a neurotic type of every illness, the stereotyped valerian or asafoetida without their abominable odor and disgust associated name, would fall most lamentably with the hysterical woman who can scarcely be treated, or even temporarily relieved, save by means of some form of mental impression.

STONE insisting that the physician's will and not that of the patient must be supreme, declares that (1) hysteria in all its forms, (2) functional neurosis, (3) any form of mimory neurosis (4) certain forms of melancholia and (5) habit cases, are the most suitable for the use of the mind cure which does not preclude the administration of suitable

remains unknown to either of the conditions of the organs of nutrition or assimilation. As nearly all such patients are victims of many psychical disturbances, he cautions the physician against letting the patient suspect he thinks her ailments are imaginary, but to let her continue to deceive herself while he wins her confidence in his professional abilities; when it will be time enough for him to drive home the haft of the wedge of suggestive therapeutics, whose thin end has been ingrafted, and in proof of this he cites some cases in which some that were grave indeed, were cured by the employment of such operations (under anesthesia) of oophorectomy, abdominal section, &c.,—*Virg. Med. Semi-Monthly*.

Facial Neuralgia, No Doloureux and Migraine.

LOOKING upon *migraine* as a nervous which may co-exist, in the same person, with trigeminal neuralgia from which it differs radically, and being quite distinguishable requires treatment with big doses of bromides, Dr. G. DE LA TOURNETTE divides facial neuralgia into three classes from a therapeutic point of view. (1) In the first form which is transitory and usually due to cold or peripheral irritation, the onset is sudden and there is an acme and a decline, while the pain during attacks is less intense though seldom absent between them. This form is always benefited by analgesics (such as antipyrin, phenacetin, hydrobromate or valerianate of quinine) which do not at all influence the (2) second form or the *doloureux*, which is completely paroxysmal and quickly reaching its maximum intensity ceases as suddenly as it came. In one day there may be from 10 to 100 attacks which may come on spontaneously or be incited by physiological acts such as laughing, chewing, blowing the nose &c and induce secondary vasomotor symptoms as injection of the eye, edema of eyelids, discharge from one nostril &c, while herpes along the nerve is common and the neuralgia lasts for weeks or months and vanishes completely for a period, but as age advances, the intervals shorten, and the painful periods lengthen until the disease is permanent, refractory and often incurable, through sometimes amenable to large doses of opium. (3). Hysterical neuralgia which is curable by suggestive treatment, may often co-exist with tic, from which it may be distinguished by the usual presence of an aura and by terminating frequently with hysterical convulsions which (latter) are never provoked by true tic.—*Rev. Méd.*

Intestinal Lithiasis and Intestinal Gravel.

DIFFER from biliary calculi in that while there is an organic element chiefly stercoval, and an inorganic one represented by magnesia and calcic salts with traces of gallic &c., there is no cholesterol and as intestinal lithiasis which is, frequently associated with it mostly appears at the same time as the membranous enteritis which it may sometimes follow, Professor DIEULAFOY, thinks intestinal sand in many cases belongs to a gouty diathesis. Apart from lead colic and the pains of gastric or duodenal ulcer, intestinal lithiasis is most likely to be mistaken for hepatic colic or appendicitis from which it may be distinguished by pseudo-membranes, sand or calculi &c, being found in the stools, and by the peculiarity of the symptoms in which abdominal tympanites is the most common preliminary. The paroxysms succeed each other rapidly and the whole attack lasts from 24 to 36 hours and is followed by the expulsion of hard faecal matter or diarrhoeal stools containing mucoid masses together with sand and gravel or calculi. The attacks are often periodical occurring some hours after repast and recurring several times a month or a year through many years. Morphine may be given during the attack and in the interim hygienic measures, dieting and treatment by mineral waters—Vichy is best—are recommended.—*Bull. de l'Acad. de Méd.*

SURGERY.

Treatment of Appendicitis.

As the true cause of this affection is probably stoppage of the drainage from the appendix to the colon, opium, though it may relieve the pain and discomfort, entirely masks the symptoms at a most important time, i. e. the first 24 hours from the beginning of the attack. MCBURNER looks upon appendicitis as a surgical rather than a medical disease, and declaring that preliminary treatment is often worse than useless, says that the chief cause of death is delay of some sort or another, and points out that while the second attack predisposes to a third, each attack renders operation, which is indicated between the attacks, more difficult and more dangerous. If when the patient be kept in bed the symptoms do not get worse in 5 or 6 hours, there is no immediate danger, and if there is still no increase in the severity of the symptoms after 12 hours, the probabilities are that he will improve without operation; but if the urgency of the case has steadily increased in 12 hours from the time diagnosis was made, it is an indication for operation, which should not be performed within 14 days after an acute attack, as in operation during an acute attack the prognosis is far from favorable, though in abscess cases the sooner we operate the better.—*Brit. Med. Jour.*

Castration and Vasectomy in Hypertrophy of the Prostate.

FAIR from recommending castration as a universal panacea for hypertrophied prostate, Dr. J. W. WHITE explains that (1) if the patient is not very old, virility good, has sound kidneys and only a moderate amount of residual urine, catheterism only is required, but (2) if the pain is marked and resists bromides, belladonna, phenacetin, &c. Vasectomy is indicated. (3) So also if the residual urine reaching 5 oz., does not diminish under catheterism or if the sexual power is weakening, and there is danger from backward pressure on the kidneys, atony of the bladder or cystitis; but (4) the younger the patient the greater his virility, the sounder his kidneys and the better his general health, the more the surgeon should incline toward prostatectomy; whereas (5) castration promises the most benefit in the worst cases where the prostate is enormous, the cystitis excessive, the bladder dilated and atonied, attention absolute and catheterism difficult or impossible. Of course any operation involves risk, but this risk must be weighed and though castration may occasionally fail, it is the best procedure and very often the improvement is marvellous.—*Lancet*.

Indications for Paracentesis of the Membrane Tympani in Otitis Media Acute.

As otologic practice is largely made up of the results of neglected or badly treated cases of otitis media, which is a complication of any disease from coryza to syphilis, V. WUNDERMANN (*The Laryngoscope*) cautions both the profession and the laity against injudicious recourse to drops, opiates and douches which often do more harm than good, and points out that (1) ear-ache being a warning sign of a dangerous disease, whose pain may be masked by opiate, the ultimate risk of the patient's life, it is wisest to let the character, localise the extent of tissue destruction, shorten the course of the disease, as well as immediately relieve the pain, mitigate the symptoms and prevent suppuration, including the membrane (before it bursts) at once detected, and the drumhead, be reddened or halcyon should the case be seen after spontaneous perforation, the hole in the drumhead should be enlarged by a curette, which gives but temporary pain, so as to permit

of profuse drainage, after which (3) the tampon should be wiped dry, rendered aseptic by disinfectant, formaline or borie wash and provided with a drainage wick of iodoform gauze, which should be changed every 3 hours. (4) The outer atmosphere must be excluded by tight plugging with absorbent cotton and (5) constitutional and general symptoms carefully attended to.

Treatment of Hemorrhoids by Dittels' Method.

Is very strongly recommended by Dr. ZUCKERKANDL, who obtained good results from it in 269 cases of internal piles with prolapse of the mucous membrane. The SCHLIECH infiltration obviates general anesthesia and deadens the pain while, by pressing, the patient forces out the masses, when the pedicle is grasped by a polyp forcep and twisted to an angle of 90°, which develops the hemorrhoid which is then tied off with tensely stretched elastic ligatures, which are allowed to remain undisturbed for 8 to 10 days, by which time the ligated masses necrose, fall off and leave a clean granulating wound which heals in about a week.—*Wein. Med. Presse.*

Massage in Surgical Practice.

ZABLUDOWSK, holds that massage is one of the most important factors of conservative surgery, and a sovereign means of quickly restoring the use of the limbs to surgical patients who have been debilitated by long confinement in bed. To injuries of the limbs and chronic articular troubles a long list of other affections, both local and general is added, in which it is stated, massage is likely to do good. This list includes peripheral circulatory disturbances; chronic gynecological diseases, hemorrhoids, and prostatic enlargement; and many abdominal complaints on the borderland of medical and surgical practice. It is indicated in many cases of paralysis of both cerebral and peripheral origin, so long as such paralysis is not associated with muscular contraction and rigidity, and exaggerated tendon reflexes. In the treatment of chronic neuritis and muscular rheumatism, massage, to do any good, must be practised with some energy. The author insists on the necessity of a long and careful training of those who intend to take up the massage treatment, and he mentions many afflictions, some of a serious nature which may result from ignorance of the details of the method, or of carelessness in its practice.—*Brit. Med. Jour.*

Asepsis in Operative Surgery.

QUENU *Rev. de Chir.*, discusses a recent paper by MIKULICZ, who holds that as a result of his personal experience and that of other German surgeons, the substitution of aseptic for antiseptic methods in surgical operations has done harm and not good. The failures that occur from time to time in the practice of very careful surgeons are attributed to the difficulty in effectually sterilising the hands and also to the discharge of pathological microbes from the mouth and nose of the operator in breathing and talking. MIKULICZ asserts that a marvellous improvement has followed his use of sterilised gloves whilst performing operations. QUENU whilst admitting the difficulty of rendering the hands pure, attaches more importance to a strict avoidance of contact with any septic patient for twenty-four hours before performing a serious operation. An ideal precaution, he states, would be for the operating surgeon never to open an abscess, or, at least, never to touch pus. He suggests the separation of wards for suppurating cases from those of aseptic cases, with a special personnel and material for each. A rectal or vaginal examination should not be made for at least a day before the operation, and, if this cannot be avoided, special care should be taken to cleanse and sterilise the skin of the hands. He is opposed to the performance of an important operation in a large theatre, and in the presence of a great number of students.—*Brit. Med. Jour.*

OBSTETRICS AND GYNECOLOGY.

Puerperal Infection.

(A) CONTACT of the physician or nurse is the most frequent cause; (B) make as few vaginal examinations as possible in obstetric practice; (C) omit the anti and post-partum douche as routine practice; (D) at the first appearance of puerperal sepsis give the parturient sexual one thorough disinfection; (E) be sure not to overlook localised pelvic inflammation which may require a major operation; (F) use stimulants fearlessly, employ injections of normal salt solution, under the skin, into the rectum and intravenously, and try the administration of nuclein; (G) before employing an antistreptococcal serum, be sure that you have to deal with a pure streptococcus infection. R. C. MORRIS.

The most constant and earliest symptoms are elevations of temperature, rapid pulse and relative or absolute insomnia. FERRIS.

For the occurrence of sepsis in child-bed the attending physician must usually hold himself to blame. Practically all causes of infection are within control, and puerperal sepsis is a preventable disease.—CHAS. JEWETT. *Canad. Pract.*

Non-ligation of the Umbilical Cord.

KELLER, in the *British Medical Journal*, in advocating non-ligation of the cord, states that he has practiced it in more than 2,000 cases, and after careful examination and observation of these cases, summarizes his views as follows:

1. Ligation is unnecessary because (a) it is not required at birth of any other animal; (b) the imagined necessity to prevent hemorrhage does not exist; (c) to tie for cleanliness is superfluous; (d) it is unreasonable to consider that such an imperfection, as needs ligation, exists.
2. Ligation is in many cases injurious because, (a) it may justly be considered the cause of secondary hemorrhage; (b) by interfering with desiccation, and thus preventing suppuration, it gives rise to ulceration with not infrequent consequences of erysipelas, fungoid excrescences, etc., (c) it causes inflammation of the funicular vessels by keeping them distended with unnaturally retained blood, hindering their normal obliteration, and laying a foundation for phlebitis, jaundice, etc., By preventing a normal escape of blood and thus causing hyperemia and congestion of the portal circulation, it may lay the foundation of numerous infantile affections apparently originating in congestion of these vessels.

(3). Numerous fatal cases attributed to ligation have been recorded by the highest authorities. It can be seen in the new-born that the ligature maintains the ventricle in a state of distension, otherwise relieved by bleeding from hypogastric arteries, and this prevents renewal of the action if the heart has stopped, or hastens its stopping if it is failing.

Treatment of Ruptured Uterus by means of Gauze pa

SHOULD the rupture occur before delivery and the child escape into the abdomen, immediate abdominal section with withdrawal of the foetus, placenta, &c., and draining of the wound after thorough lavage of the abdominal cavity with a solution of sodic chlorid in water (teaspoonful to the pint) maintained at 105° F., will save the patient's life; but should the rupture occur in the lower segment of the womb, during delivery, Mr. A. W. MAYORHOBSON F.R.C.S., (practitioner) thinks the probabilities are of its passing unnoticed for some time, as the shock may

not be immediate use the hemorrhage. It is difficult to produce immediate collapse, and simple vaginal examination may not discover the rupture. Hysterectomy is scarcely practicable and the best plan is to curette and wash out the fundus of the uterus; compress the abdomen so as to force all the free blood possible out of it, after which pack the laceration very thoroughly with long strips of iodoform gauze, several yards perhaps—and apply a firm pad, held in place by an abdominal bandage, over the pubes.—*Proc.*

Advantages of Vaginal Section for Pelvic Suppuration and Circumscribed Hemorrhage.

The above are highly extolled by Dr. EDWARD NICHOLAS LITTLE, who claims that it lessens the risks attending abdominal section to which it is much to be preferred, and having for its main object the breaking up of adhesions and removal of vague pelvic pains, is unequalled as an exploratory measure for purposes of differential diagnosis, and it is a solemn fact that when PEAN, JACOBS, SEGOND and other gynecologists removed diseased uteri and pus tubes by vaginal section, they met with greater success in their more serious cases than when they employed abdominal section. To blindly follow in the wake of any group of enthusiasts is at all times injudicious and though it is not always an easy matter to decide upon the operative procedure most proper for the good of the patient, and yielding the best results, still if it is a very extensive lesion that cannot be reached *per vaginam*, it is needless to open the peritoneal cavity, while there is much less danger in operating *per vaginam* in the TRENDLENBURG position. True there are instances where abdominal section is imperative; but even in the majority of instances where vaginal section and efficient drainage are but relief not cure measures, the local conditions may be so changed that a subsequent operation for removal of the appendages and uterus would not be relatively dangerous.—*Med. Rec.*

New Method to Restore an Asphyxiated Child.

STINGER calls attention to the fact that the asphyxiation of an infant after a difficult labor, being due to a lack of oxygen, may be overcome if the blood is kept oxygenated, until the sensitiveness of the child is sufficiently restored to permit normal breathing to begin. He discovered quite by accident that this oxygenation may go on through the surface of the placenta if the latter is exposed to the air. Having had a miscarriage case at the fifth month, in which the fetus, the membranes, and the placenta all came away together, he wrapped up the specimen with the intention of examining it the following morning. Great was his surprise to find several hours later that there was still a pulsation of the heart. Life had evidently been prolonged by the aeration of the blood, which took place through the placenta. STINGER has since had occasion to test this method in the case of several full-term children born asphyxiated, and has found it to work admirably. As such cases usually follow long and difficult labors, the placenta is already separated in whole or in part, so that its removal does not present any difficulty. It is to be removed as soon as possible, its surface washed and exposed to the air, when the child will live an indefinite time, as it did in the uterus, without respiration. When respiration begins, which was not for twenty-five minutes in some of the cases, palpation in the cord will cease, and it may be tied and cut.—*Med. News.*

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

Muscular Movements and the Heart's Action.

AMONG many interesting points determined by Dr. AUGUST STRAUSS, in his investigation of treating cardiac instability by muscular exercises are the facts that even in health (1) the same exercises on different occasions and in the same individual gave varying results so that (2) the degree of force employed on different occasions must be regulated by its apparent effect and (3) though the immediate effect of the exercises was to induce well-marked diastolism or the TRAUBE-HERING curve of the pulse and exaggerated respiration indicating rhythmical action of the vasomotor centre still (4) the heart, accelerated by exercise, *very rapidly* recovers its average rate of pulsation in periods varying from 2 minutes upwards to 5 in accordance with the age and vigour of the person. All this pointing to the influence of exercise of the heart's action and suggesting its employment in cardiac therapeutics.—*Dtsch. Arch. f. Klin. Med.*

Paroxysmal Tachycardia.

WHILE admitting the frequent failures of all the remedies employed, Dr. WATSON WILLIAMS found digitalis more useful than any other drug in the intervals between the severe and prolonged attacks of paroxysmal tachycardia, which, he thinks, is due to a neurosis of the intra-cardiac ganglia, which leads to dilatation and functional disease of the heart, whose inherent rhythmicality appears to suddenly pass beyond the control of both sets of regulating nerves, in those cases where a generally enfeebled nervous system is immediately excited by some sudden loss of emotional or other energy.—*Brit. Med. Chir. Jour.*

Some Causative Factors in Ulceration of the Cornea

HAVING noticed that almost every child he treated for corneal ulcer had an irritating nasal discharge that produced eczematous condition of the skin about the nose, and thinking it quite possible that the condition of the nasal mucous membrane had a good deal to do with causing the eye trouble, Dr. FRANK EDSALL treated the nasal and eye troubles conjointly, and had such good results that he advises the routine practice of giving the nasal trouble and the corneal ulcer the same attention, as he believes that the ocular trouble is undoubtedly of bacterial origin with the infection propagated from the nasal cavity.

He also insists that all forms of corneal ulcers demand close enquiry into the refractive state of the affected eye; as the refractive most prone to cause disturbance in the nutrition of the cornea is a myopic astigmatism, although the cornea may be involved in an inflammatory affection arising from excessive demand upon the ciliary muscle, dependent upon almost any of the various refractive errors, and there is no special characteristic of this form of corneal trouble to distinguish it from other corneal ulcerations, beyond its tendency to recur.—*Ophthalm. Record.*

Bacteriology of Infantile Diarrhoea.

THOUGH our knowledge is imperfect regarding the specific agents at work, everything points to this disease being due to the changes produced by bacteria in the milk. While MACFADYEN, NENOKI, and SWINER show that the bacteria of the small intestine primarily decompose carbohydrates to produce an acid reaction which is a main factor under normal conditions, in preventing the development of putrefactive decomposition, EICHENHORN who found no specific organisms in the milk faeces he examined, thinks the diarrhoea

due to *alcoholism* and *fermentation* by *bacteria*, of which the two predominant varieties, *A. B. coli commune* and *B. lactis aerogenes*—cause fermentative, not putrefactive, changes in the milk sugar and the chief products of their action are acetic and lactic acid and CO_2 and H_2 gas. He further suggests that it is through their action on the milk and not by direct invasion of the body, that the bacteria acquire their dangerous properties on children who are subject to toxic influences that may not affect the adult.

BOOKER isolated 88 forms of bacteria from cases of infantile diarrhoea; but BAGINSKY, who did not find specific organisms in 48 cases of summer diarrhoea, is of opinion that saprophytes may produce this disease, the severe forms of which seem due to bacterial poisons developed from the proteid constituents of the food, and which VAUGHAN who has isolated from poisonous milk, a crystalline body (tyrotoxin) capable of producing symptoms resembling cholera infantum, believes that there are many bacteria which may produce diarrhoea in children by an action on the milk inside or outside of the body, there is little doubt that milk suffers a profound decomposition in hot weather than the ordinary lactic acid fermentation, and these changes may occur without visible alteration in the appearance of the milk. Even sterilised milk is not without danger and FLUGG proved that the heat of sterilisation does not kill several pathogenic bacilli. Milk therefore furnishes a better field for investigation than does the intestine, and if the living agents at work in the milk were accurately known, means could be adopted for their extinction and for the prevention of the diseases they evoke.—*Brit. Med. Jour.* 1905

Test-tube Reactions Between Cobra Poison and its Antitoxin.

WAS the title of an interesting paper read before the Pathological Society of London, by Dr. J. W. W. STEPHENS and Mr. W. MYERS, whose experiments were made with a view to ascertain whether (1) the cells of the animal body are necessary for the action of an antitoxin to make itself felt or (2) whether the antitoxin and toxin react chemically on each other, and this without the assistance of the living organism, as well as to look for other reactions between a toxin and its antitoxin *in vitro* and at Professor KANTHACK's suggestion they were led to examine.—(1) The action of cobra poison on the blood *in vitro*, (2) how CALMETTE's antitoxin affects this action and (3) whether the neutral point is the same *in corpore* as it is *in vitro* for the animal whose blood was experimented upon. After pointing out the necessity for dissolving the poison in solutions that were isotonic or only slightly hypertonic, for the particular blood under examination, they say that the hemolytic action could be completely arrested by definite quantities of serum but that while 0.1 c.c. of isotonic serum always sufficed to arrest the hemolytic action of 0.1 mg poison on guinea pigs' blood, larger amounts of poison, although completely neutralised as regarded hemolysis proved rapidly fatal when injected into animals. This leads them to the conclusion that snake poisons, being composed of two or more proteid constituents may contain, in addition to the toxic substance which is neutralised by the serum, another toxic substance which is not so neutralised by the amount requisite to prevent hemolysis. They agree that the toxin and antitoxin react chemically *in vitro*, and they summarise their results thus:—(1) Cobra poison is strongly hemolytic *in vitro* and (2) is neutralised by antivenomous serum whose action is specific. (3) This neutralisation is chemical, not cellular nor vital and (4) in certain doses the measure of this neutralisation *in vitro* is a measure of the neutralisation *in corpore* for guinea-pigs.—*N. Y. Med. Jour.*

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Care and Feeding of Premature Infants.

THE MORE premature the baby the less its power to produce heat and the greater its capability of losing heat. Hence Dr. G. F. BLACKER points out the necessity for (1) protecting such a child from light and impure air and (2) carefully guarding it from cold as well as (3). Keeping it at an equable temperature and (4). Supplying it with nourishment in an easily digestible form, besides (5) Weighing it once a day, to ascertain whether it is thriving, and (6) twice a day taking its temperature a recte as to regulate the temperature of the air surrounding it—the Lien or HARRISON's pattern preferably—admirably fulfils conditions 1, 2 and 3. As soon as a premature babe is born, it should, its face excepted, be completely enveloped in cotton wool and placed in the incubator, with an absorbent cotton pad under its buttocks to catch the feces and urine. This pad should be changed twice daily and weighed to determine the quantity of excreta passed. The window of the incubator should be covered with a dark cloth until the child is nearly full term and on no account should a premature baby be bathed until it can be taken permanently out of the apparatus. Many premature babies do well upon their mothers' milk, which should be drawn off into a BABCOX's dropper and the child given 1 to 2 drachms at a time at 3 hour intervals. If administration of food by the dropper causes vomiting, *gavage* must be resorted to. Sometimes the mother's milk, even when diluted, does not agree with the child for whom modified milk containing proteid, 0.5 per cent., fat 1.0 and sugar 3.0 per cent., must be prepared by ROTON's method and strengthened as the child grows. If modified milk cannot be had, the child must be fed upon humanised milk or condensed milk, diluted if necessary, or upon boiled cow's milk, mixed with 4 parts of water and a teaspoonful of cream to the ounce.—*Med. Rec.*

Climate or Environment as a factor in the Repair of Neurasthenia and Melancholia.

FOR the large class of sufferers from mental depression and the consequences of excessive dissipation, who refuse systematic medical treatment, but are quite willing to try a "change of climate." Dr. J. M. TAYLOR thinks environment and suitable companionship is of more importance than the climate itself. As to the advantage claimed for radical geographical changes—escape from a cold winter being the most popular and most conspicuous—he admits that the warmth and sunlight of some tropical climates afford opportunities for outing which cannot be gained, but thinks it is a question whether the removal of the season is valuable for those lacking in vascular and nervous tone, and for whom cold under suitable precautions is an invaluable tonic, while there is nothing like pleasant environment and genial companionship for the rapid and radical cure of many nervous affections. Besides which for the tens who can, there are thousands who cannot afford to go for a "change of climate."—*Bent. Med. and Surg. Journ.*

Kitchen Bacteriology.

A KÖNIGSBERG doctor, *Privat-docent* Dr. JAGGER, recently gave a course of hygiene and bacteriology for ladies, which included practical exercises in applied bacteriology, for instance, in the preparation and preservation of food by methods used in bacteriological work. At the close of the lectures, the hearers were allowed to invite the friends to an exhibition of kitchen products—some raw and some cooked—that had remained in a warm room for periods varying from five to sixteen days, and which were all found perfectly

these and other things, and "kitchen bacteriology" and "kitchen hygiene" had any complicated procedure been required to attain this result. The method simply consists in: (1) The use of vessels with well fitting, overlapping lids, instead of the inside lids used in kitchens all the world over, which allow stray bits of matter that may adhere to their rim to fall into the food; (2) avoidance of opening the vessels in which the food was kept, or where this was indispensable, careful manipulation as in bacteriological work; and (3) the use of cotton-wool as a covering. Cotton-wool lids had been specially prepared to fit the wide tops of the food vessels, they consisted of a circular disc of cotton-wool, tightly held between two metal rings, the outer of which formed the overlapping rim of the lid. It is to be hoped that Dr. JAGGE will find imitators, and that "kitchen bacteriology" may become a study with ladies. Certainly there is much room for improvement in the old-fashioned kitchen methods to which our "family plain cooks" cling with such desperate energy, and which they seem to regard with an almost superstitious reverence.—*Brit. Med. Jour.*

When may Women with Heart Disease Marry.

Dr. KIRCH said the chief points to be considered are: (1) the kind of heart disease; (2) its duration; (3) the presence or absence of compensation; (4) the general health; (5) the social position of the patient.

(a) They may marry if the disease is not of long standing and compensation is good, and the general health not undermined. They will have during pregnancy, and still more during and after delivery, many troubles due to their heart, but in by far the greater number of cases there will be no danger to life. This applies to well-compensated mitral regurgitation and stenosis, aortic regurgitation, fairly marked sequelae of pericarditis, and to muscular degeneration if not too far advanced. The patients must also be in a position to spare themselves bodily exertion as much as possible during pregnancy, to avoid mental excitement, and to have constant medical supervision.

(b) The prognosis is not so good if the patients are very anemic or nervous, or advanced in years, or if the valvular disease is congenital or acquired in childhood. In these cases the physician should advise against marriage, or at any rate point out that the disease will most certainly become worse after marriage.

(c) Marriage is to be absolutely forbidden as dangerous to life when compensation is failing, or when there is advanced muscular degeneration. In all cases where there is dyspnoea, palpitation and quickened pulse on slight exertion, or marked oedema not disappearing after rest in bed, when there is tendency to arrhythmia, scanty urine with albumin, and attacks of irregular small pulse, coldness of the extremities, nausea, dyspnoea, syncope, &c., marriage is dangerous, whether the cause of the symptoms be valvular disease, diseased arteries or cardiac muscle. Even those for whom marriage is allowable must follow certain rules strictly.

1. Coitus must not be frequent, and must be continued to the end of the orgasm, otherwise reflex heart troubles and depression result.

2. They must not have more than one or two children, as the strength of a diseased heart diminishes with every pregnancy in geometrical progression. If this rule is followed, induction of premature labour will be luckily seldom necessary, since when it is the results are very unfavourable.

THE THERAPEUTICS AND PHARMACOLOGY.

Chemistry of Diabetic Foods.

THE strictest antidiabetic diet consists of meat soup, coffee, tea, eggs, meat, green vegetables, bacon, butter and about 800 grammes (nearly 3x) of conglutin bread, which (last) is supposed to contain less than 40 per cent of that bag bean, the carbohydrates, as against the average 60 per cent contained by ordinary wheaten bread; but Professor VON NOORDEN, finds that the composition of diabetic bread is by no means constant in this dreaded constituent, which is not only much more often in excess of than below 50 per cent., but also frequently exceeds 60 per cent, while Dr. F. KRAUS, shows that while potatoes contain only 15, Jerusalem artichokes 16 and fruit, so valuable an addition to a diabetic dietary, from 4 to about 14 per cent. of the objectionable carbohydrates against the anywhere from 80 to 66 per cent. contained by gluten bread, simple cooking still farther deprives many fruits and vegetables of their carbohydrate components. Thus a raw apple that contained 11.7 per cent. of carbohydrates lost 44 per cent. when once stewed and 5.6 twice cooked and peaches holding 9.5 per cent. when raw contained only 1.8 per cent. after cooking. Of course the water in which such fruit &c. is stewed should be thrown away and it follows that it is much safer to give definite quantities of natural foods, than even limited amounts of the less palatable and more expensive specially prepared articles of uncertain composition.—*Brit. Med. Jour.*

Unexpected Effects of Bromides.

SUCH absolute belief is placed in the ability of the bromides to control the nervous system that most physicians are apt to attribute the symptoms, induced by these drugs to the primary neurotic condition of the patient. but HODGES points out that, while the potassic-salt is the most powerful and the sodic salt the least toxic of the bromides, the continued use of either or both these drugs increases the irritability of temperament, and directly induces to depression of spirits with a tendency to moderate melancholia or homicidal or suicidal impulses. It impairs the memory and the contractility of the muscles as well as irritates the gastric mucous membrane and disturbs the circulation, while it also promotes an extraordinary susceptibility to toxic effect in cases of cerebral lesions &c.—*Drug. Chic.*

Remedial Value of Veratrum Viride.

LIES in its influence on the heart, whose action it retards in acute inflammatory diseases with a very greatly accelerated pulse. BATTEN found this drug particularly useful in inflammatory rheumatism, and the early stages of measles, scarlet fever and small pox; while in typhoid fever where the heart's action was irregular, it was steadied by drop doses of NORWOOD's tincture of veratrum viride which also proved an excellent remedy in inflammatory diseases of the chest, notably acute and pleuro-pneumonia and pleurisy. If in acute pneumonia, in the congestion stage the pulse can be kept at or near the normal by this drug, it may often be jugulated or prevented from entering upon the hepatization stage. Even in the second stage of a sthenic case veratrum acts well, since it reduces blood pressure and lessens the heart's action without loss of blood, as in venesection.—*Jour. Amer. Med. Assoc.*

Calcium Sulphide as a Depilatory.

Is so harmless to the skin that it may be left on any length of time without irritating abraded surfaces even when the powder is made into a paste with water. Dr. A. W. BRAYTON, of Indianapolis calls this powder 'calcium sulphide' and says that it can be prepared by the same pro-

cess as calx sulphurata, though the usual way of producing the 'sulphate' is by super-saturating milk of lime with sulphuretted hydrogen.—*Jour. Amer. Med. Assoc.*

For Sick Headache.

DR. ALBERT C. BARNES, of the Philadelphia Polyclinic, recommends the addition of oil of cajuputi to GREENE GRIFFITH'S alkaline aromatic mixture for "sick" headache. The amended formula would read as follows:—

R. Ol. caryophylli	3 i
Ol. cajuputi	3 ij
Sodii bicarb	3 ij
Chloroform	gtt. cxx
Tr. cardamomi comp.	...	qs. ad.	3 ij

S. Teaspoonful to be taken after each meal.—*Galillard's Med. Jour.*

Successful Treatment of Tuberculosis.

CHARLES WILSON INGHAM, of Binghampton, states that, after five years' use in the treatment of all forms of phthisis, the compound given below has proved so satisfactory and generally applicable that he has made no alterations or additions to the original formula. It is prepared for hypodermic use only, sterilized oil being the solvent used:—

Iodine (chemically pure)	gr. ½
Bromine (chemically pure)	gr. ¼
Phosphorus (chemically pure)	gr. 1/10
Thymol (chemically pure)	gr. ¼
Menthol (chemically pure)	gr. ½

—*Med. World.*

Ninety per cent. of all cases are reported cured by the Iodine-Bromine compound.—*N. Y. Med. Jour.*

For Cough.

FREY recommends parenchymatous injections of the following solution:—

R. Iodoform	grs. xv

INDIAN AND ANGLO-INDIAN VERSUS BRITISH PLAGUE DOCTORS AND PLAGUE NURSES.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—All through Nature, the mother, is ready to lay down her life for her offspring from whom she takes nothing though she gives them *everything* until they are big and strong enough to fight life's battle unaided, and can return her the compliment of protecting her in her declining days or in the hour of danger. Every other Christian country looks to her own first, her mixed bloods next and lastly those she has won by the sword; but England, kind mother England, who spilled rivers of blood to abolish slavery and spent millions of sovereigns to reclaim savages from paganism forgets, or is made to forget, that but for her Indian mixed-bloods (i.e. Eurasians, East Indians and Anglo-Indians) who willingly laid down their lives in her defence, her mighty Empire in the East would have been swept out of her hands in 1857. Yet while she lavishes favors and bestows almost unlimited power on the descendants of the conquered and the mutineers, she takes everything that can be taken from the children of those very Eurasians, who helped her win and keep India, and in remembrance of their parents' brave deeds and invaluable services to her, bars them from her army, shuts even the doors of her ships' forecables against them, and ostracising them from every one of the official posts worth having, now extends the cruel and totally undeserved *memento mori eupharis* to their sisters.

I preach no sedition, though I feel the position keenly as I belong to a warrior race, whose pen, sword and brain have for generations past been *always* ready in Britain's Cause. My people piloted her mercantile and war ships through the dangerous waterways of Bengal. We backed her with our swords in dreadful, 1857, as well as placed our purses at her disposal and fearlessly wielding our pens against her defamers or detractors, furnished a large proportion of her Medical and Judicial Services. To what end? God knows. Wrested of my landed properties through State maladministration and myself hounded from pillar to post, I have the consolation (???) of knowing that my children who, though white skinned, have been born in India, can never aspire to anything and can barely hope to have sufficient to keep soul and body together when they grow up. The merchant offices will not give them work, except on starvation wages. I cannot send them to England to pass out in the Covenantated Services, because, through no fault of mine, I have not the means to do so. A Mahomedan or Hindu can enlist and win a commission; but my boys cannot, because though Indian-born, they are not Indians, and not being British-born have no claim to British privileges. If my children study medicine and pass out ever so high, they have the disadvantage of having government doctors compete against them, in private practice, by gazette notifications of counternaming medical certificates, and unnecessary charitable dispensaries that deprive the non-officials of thousands of patients, and they constantly run the risk of their claims to recognition being deliberately ignored in cases of state need, as has been done in this present

plague-punk, whose indigence and highly educated as well as experienced talent has been cruelly and criminally passed over stoningly, while British doctors and British nurses who know absolutely nothing, except in doubtful theory, of the diseases and customs of Hindustan have deliberately been imported to deal with plague and plague patients in India. Is anything more ridiculous, and yet could there be greater injustice or worse cruelty.

I am not the only father whose heart bleeds for the hard future of his children. Hundreds, yes, thousands are as similarly situated as I am. We know and feel that we are unjustly and unkindly treated. Does England know it? I think not, India is one mob of officialism which rides roughshod over us. If we complain we are boycotted and made to run the gauntlet of unnumbered woes. The so-called Inquiries or Royal Commissions on Labor, Opium, Eurasians &c., are impious farces, from which everything that savors of contradiction of preconceived official fads, is carefully excluded, or the truth as carefully occluded by meaningless verbosity, so that Parliament can see India not as India really is, but as a few interested officials choose to paint her.

And even though a large number of officials are in verity Anglo Indians or Eurasians, they will not admit it, lest by being removed from class A of the Register (where they have not the right to be) they would be denied the privileges extended to the British-born or British-educated, and come under the withering definition—"Nobody there but Eurasians and shady people of all sorts. (Eurasians are). Children of mixed blood Fathers, English—mothers, niggers. Deuced pretty creatures some of them, by-the-bye. But nobody (nice &c, respectable) goes to see *them* of course. Caste is a great thing in India. I'm not sure but the niggers are right after all about it" hurled at them by writers of the Captain FRED WHITTAKER sort, whose ideas of physical geography are particularly hazy, when they talk of reaching Bombay *within* three days by rail from Darjeeling, where they claim to have seen Rajahs driving about in four-in-hand drags. Rubbish like this is sewn broadcast among the masses of the English at Home, till the entire nation (i.e. such as have not been to India) have got to believe and the very soldiery look down on the Eurasians as "Half caste," a term now converted into so opprobrious an epithet of abuse, that when one Eurasian wishes to mortally offend another he calls him a 'Half Caste'. An official therefore who openly avows himself an Eurasian is a man of no small courage, for by such an admission he courts the enmity of his own cloth.

Look at another side of the picture, a awful though true one. Loss of caste in Indian views is forfeiture of happiness in the world to come. The moment an Indian woman marries a European her immediate relatives look upon her as spiritually and bodily DEAD. Her name is never mentioned in the home of her girlhood and her priests curse her. Who wrought this desolation. Her European husband to whom she bears children whom their paternal aunts look down upon if they are dark skinned but, perhaps, make much of if they are white. Children are apt learners. This fish and fowl business grows in them and it is no uncommon thing to have brothers and sisters disowning each other on account of "shades of color" and

often a son who has been sent to England for education and returned to this country in some official capacity, will refuse to recognise his Indian mother.

I could for the edification of Lord GLENHAMPTON (who by the way has not yet redeemed a fraction of the promises he made you last year) mention several instances of this among the immaculate *Indian Medical Service* who are mainly responsible—if not wholly so,—for the unpardonable sin of sending to England for plague doctors and plague nurses when they could easily and at much less expense, have found them among their own brothers, sisters and cousins in India. What their real reason for excluding indigenous talent is I cannot tell, unless it be, they thought it unwise to associate themselves or acknowledge direct kinship with folk who, knowing that there is no such thing as a thorough blood man or person of unmixed parent descent in the whole world, throw conventionalities to the winds, and like me are not ashamed to admit himself or herself an Anglo-Indian.

Yours &c, R. C.

CALCUTTA, 15th August 1898.

—:O:—

THE C D ACTS IN INDIA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I have read X Y Z's letter in your last issue, and it appears to me that if she had nothing of more importance to say in reply to my criticisms on the Memorial for which she and 78 other medical women are responsible, the golden rule of silence would have been the better course.

She thinks however that one of my statements is directly contradicted by Lord LISTER and accordingly his authority is brought forward to confound and crush me, that the contradiction exists only in her own imagination will not I think be very difficult to show.

In the Memorial it was stated that there were certain distinctions between venereal disease and other contagious diseases, in that, "other contagious diseases are, as a rule, easily recognised, rarely or with difficulty concealed, treatment is voluntarily sought" etc.

From these propositions I ventured to differ and said "it is manifestly absurd to state that venereal diseases are more difficult to recognise than typhoid fever."

To prove that I am wrong in this opinion, Lord LISTER is quoted as saying "In the early stages of the complaint (venereal disease) there is no general effect whatsoever produced upon the system. The person appears to all ordinary examinations perfectly healthy, and it is only by special examinations that evidence of the disease can be obtained."

This simply means that it is very difficult to recognise venereal disease *without a special examination*.

What my statement amounted to was, that after a thorough examination venereal disease was more easily diagnosed than typhoid fever.

Why X. Y. Z. should assume that my statement referred to such a barren topic as the relative difficulties of recognising different diseases *without examination*, as for instance by watching people pass in the street, I am at a loss to understand.

It will be observed that Lord Lister draws a distinction between preliminary examinations and special examinations, and to explain this it is necessary to remember that he was addressing a non-medical audience and that under the circumstances the words were proper and conveyed a special meaning. For the physician, however, no such distinction exists, every examination for the detection of disease is a special examination directed to the organ or organs diseased; if an ordinary examination is to be understood as one which carefully avoids any investigation of the affected part, then there is no such thing.

From this it is clear, not only that Lord Lister's statement does not clash with mine, but that they have nothing in common.

There is, however, another sense in which venereal disease is more easy to recognise than most of the other contagious and infectious diseases, that is by the person affected; in the majority of cases people suffering from venereal diseases are aware of it, it is the reverse with the other diseases referred to.

With respect to the questions of concealment and voluntarily sought treatment, the statements in the Memorial are true for England, they are not true for India; and as the Memorial "is wholly and solely directed to India, it is certainly misleading to argue on an English basis.

Further the favourable conditions that prevail in England are entirely due to compulsory legislation, and it does not appear to have thrown much work into the hands of the quacks as X. Y. Z. assumes it would do in the case of venereal.

A large part of the letter is taken up with exposing the difficulties in the way of dealing with venereal on precisely the same lines as the other diseases that are notifiable in England; but as it has always been considered necessary to draft a special act for dealing with venereal, which shows that there is no intention of trying to deal with it on precisely the same lines, this part is irrelevant.

To my mind the most important thing about venereal disease is that it is chiefly fostered and spread by a special, distinctive, and separate class; and that this class has, in India, become a source of danger not only to the British Army, but to innocent women and children at home. This state of things, which is nowhere denied, appears to justify the strongest repressive measures.

Such measures are more likely to succeed under the simple conditions that prevail in India, than in the large European capitals.

It is futile to deny that such measures can have any good effect, for, putting my own experience aside, I take the action of the Government as the strongest proof that the evidence before it was overwhelming in its strength, otherwise no Government would have ever faced such an unsavoury and unpopular task.

X. Y. Z. says it is interesting to put some statements of M. LECOUR'S which she quotes, beside a statement of Dr. COMMENCE, quoted by me. It may be interesting, but what the former says does not refute the opinions of the latter, neither does it prove that legislation is powerless to check venereal disease; if it proves anything it is that the administration was not quite up to its work. There is nothing to show to what extent

venereal diseases would have increased, had all legislation been relaxed.

X. Y. Z. says "there is no reason to think the state of things in Paris is any better to-day" than it was 24 years ago; but on the other hand there is equally no reason to believe that it is not.

The words "the trade of prostitution" appear in this letter in inverted commas, as if it was a quotation from my former letter, but it is not, the phrase is not mine.

I am a bit puzzled by X.Y.Z.'s personal allusions, she says that my wrath was specially aroused by one portion of the Memorial, that another made one too indignant to be civil, and that I treated the moral question with cheap sneers, now I think that any one who reads my letter will acquit me of these charges, which I consider quite unfounded and uncalled for.

I can find no evidence of wrath or indignation, and as for sneers, there are absolutely none, cheap or otherwise.

Yours &c, A MEDICAL MAN.

P.S.—In an original article which appeared in your journal on the 1st June 1898, Dr William Huntly says in the second paragraph. "A medical man begins badly. He says 79 medical ladies: the number noted in the *British Medical Journal* for 26th February 1898, is 78. It would hardly be worth while noting this, only that loose manipulation of figures is and has been characteristic of his party."

Also for accuracy and the *British Medical Journal*, the number was 79 after all, as X. Y. Z.'s letter shows, perhaps Dr. Huntly will be glad of the occasion to retract. By the way I never made use of the obnoxious word ladies.—Medical ladies!! Does Dr. Huntly think there is anything offensive in the word woman?

Yours &c., A MEDICAL MAN.

GOVERNMENT DOCTORS AND PRIVATE PRACTICE.

I.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The *Eastern Guardian* the leading Anglo-Indian newspaper of Madras, has the following Editorial on the above subjects in its issue of the 2nd July:—

The Indian Medical Association has memorialized the Government of India that "the public needs of the inhabitants of large Indian cities, more specially provincial capitals and hill stations, have materially altered during the past ten years, and that in all these centres there is a sufficiency of British medical practitioners, as well as highly-trained and fully-qualified Indian graduates of medicine, to supply the needs of the public, both European and Indian, and that, therefore, the time for withdrawing the privilege of private practice to State-paid doctors has unquestionably arrived." We summarize the views on this important matter. We know of no valid reason why a country, which can support its own tradesmen and schoolmasters, its own chemists and lawyers, should be so hopelessly unable to find employment for doctors. The very fact that private men are now to be found in almost every big station in India clearly indicates that there is work for them, though the conditions of service may not be entirely in their favor. It is in the power of Government to readjust a policy which may have been defensible years ago, but which is now entirely out of place in the present circumstances of the country. One of the objections to the abolition of the big Civil Surgeoncies is said to be that all Government servants are entitled to the services of an official practitioner, either free or at reduced rates, and they insist upon having the best men

available—a very dog-in-the-manger objection at best. There is no reason to suppose that private doctors would necessarily be had any more than the Government ones will be good. All Civil Surgeons are not clever while some are decidedly the reverse. Nor need we fear that Government servants will have to pay more, because the competition for patients in every large city will be sufficiently keen to keep fees within reasonable limits. Besides there is no reason whatever why any particular class of people should be pampered in their demands for this, that, or the other thing. The man who enters Government service now will be equally willing to do so whether he gets free medical attendance or not, so great is the struggle for existence. The same argument applies to the second objection—that if private practice were prohibited an inferior class of men would enter the Indian Medical Service. This is not so certain. Given a fair prospect in life, and we are perfectly certain there would be no deterioration in the existing personnel. Any unprejudiced individual looking at the conditions of modern life must acknowledge that very few men are in a position now-a-days to decline half a loaf because they cannot get the whole. When London M.D.s are content to act as club doctors, it is inconceivable that their sons will refuse the assured prospects of an official career in India simply because some parasites have been within drawn from it. The men who shook the pagoda tree i-years gone by, would probably have laughed at the idea that their better educated descendants would be perfectly happy under less fortunate conditions, and it is quite likely that the generation, to come will regard us with the envy as we do the one that is past, and withal be content.

Yet a third objection is that the conditions under which he hold India are such that any reduction as will be inevitable, in the numerical strength of the Indian Medical Service would be fatal from the point of view of public exigency. That there is some force in the objection at first sight we admit, but it should be borne in mind that as British rule in India grows in years, its military aspect must diminish, as civil power tends to increase. We need not be thinking of riots and mobs which concern the police more than the military, and which cannot possibly affect a technical discussion such as this, even though their frequent occurrence should serve to remind us of the want of cordial relations between the rulers and ruled. It is to the chance of real war breaking out that the objection specially referred. The obligation of the Civil Surgeon to revert to military duty whenever occasion arises would not, of course, hold with the private doctor, and this might seem a serious objection to his recognition by the Government. It would, however, only apply in the case of a large reduction in the Indian Medical Service, and not to the experimental measure to abolish Civil Surgeoncies only in the large cities of India. The Indian Medical Association does not go so far as this, for while claiming more work for the private practitioner, it leaves the Civil Surgeon precisely where he is. It seems to us, however, that if the medical administration of a district which nowhere is very onerous, can be conveniently delegated to the skilled members of the Sub-

ordinate Medical Service, it would be absurd to allow the dim shadow of a big war to interfere with an experiment from which much good might be gained; neither can we imagine that the abolition of, say, a dozen appointments will materially endanger the military needs of the country or diminish the efficiency of its war footing. Clearly the Indian Medical Association does not go far enough. The object was to find an opening for those Anglo-Indian youths whose parents, while quite prepared to give them the best available medical training to be had in India, are yet unable to send them to England. Whether they "can be utilised in the place of some of the men who now come out from Home is surely well worth an intelligent trial."

The above article gives a very fair view of the case, and I think it greatly strengthens the cause of local practitioners.

Yours &c., MADRAS.

—:O:—

II.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—While it is perfectly certain that a Government aided paper like the *Pioneer* is never likely to run down the baneful system of allowing state paid servants from doing private work for remuneration, it is a safe criterion of honesty to find a sturdy independent journal like *The Bengal Times* express its opinion on the question of "Government doctors and private practice. The following is an editorial from a recent number of the *Times* :—

"Where a field like Calcutta, or any town with a large Christian community offers a field for private medical practice, we consider it an abuse of privilege for a State-paid doctor to compete with private practice, and to try and monopolise those few crumbs, which are left untouched, by their overworked and fatted seniors. Our reasons are obvious. A State-paid officer has opportunities of obtaining introductions to families, amongst those in circumstances to remunerate his visits, which a private practitioner, unless possessed of considerable social influence, would rarely find means to utilise. He would necessarily have to work his way up from a humble class of patients, possibly, unable to offer him his orthodox guinea—or its Indian equivalent—a gold mohur—per visit. And for a long slice out of his life, he might continue to be a struggling man, living from hand to mouth. It is a question of years for a man to rise in India, however talented and skilful. And in this wise, London and Calcutta differ widely. In our British Metropolis, a mere accident has led to fortune, through a rich *clientele*, rapidly acquired by a multiplication of introductions. In Calcutta, such a stroke of good luck is so highly improbable, as to be next to impossible. Hence, a private, or non-official physician, begins his career faced by unfairly-advantaged competition, by men of assured income and connexion, and he feels handicapped to obscurity. He must, to emerge from a station in which his talents are buried, either submit to rub along upon a pittance that means barely bread and cheese to him—and not too much of either—join some fashionable physician, if he can obtain a chance, or add to his small means by some work not quite within professional prescription, although, perhaps, not actually exclud-

ed by any rule of practice. He finds himself in a false position, with merit unrecognised, nay, without an opportunity of recognition; without private resources, and with a hopeless vista of grappling with poverty, which indubitably implies a reproach, that often, to ignorant, or unreflective minds, suggests absence of capacity, for, how can a poor man, they argue, be a capable man? If capable, he would, as a matter of course, be well-to-do. This is how many argue, and it would be difficult to persuade them otherwise. In but too many positions of life, we observe this disposition to sacrifice talent, homely clad and with a light purse, to opulent noodledom, riding in a well-appointed Brougham. Thus, in all respects, a non-official competitor is forced into a different and disadvantageous starting-point, far behind his official rivals, who canter ahead unembarrassed, without an anxious thought, whilst he is fighting his way, step by step, with possibly, a sinking heart, or at least, with chilled hopes, almost despairing of an eventual position of independence. Again, a private practitioner is under another serious disability. He is in a special sense, a public servant, and is expected to be ready to respond to any summons for his aid, be it at night, or in daylight; in sunshine, or in storm. He may imperil his health and his life, and all for a patient who postpones payment of his fees, till, out of sheer disgust, he abandons his claim. Not so, a State-entertained doctor. He is a *public servant also*, but only *technically* so. He need not turn out of a comfortable bed to face a storm, he need not have a misgiving as to his fee. He may refuse to attend a call, and decidedly decline to quit home without his legitimate fee, cash in hand, is paid, before he will consent to stir out of doors. He can afford to be independent, since his Government salary suffices for his comfortable support, and his extra fees are mere windfalls whilst, to a non-service practitioner, they mean daily bread. Thus, again, his position and prospects are subject to a heavy discount, by comparison, and seeing at what odds competition with well-salaried men—official practitioners—is possible, we are clearly of opinion Government should, in all fairness, equalise them. Outside large concentrated groups of social fraternity, as in Mofussil towns, Government doctors—Civil Surgeons—have never been known to decline attendance, though perhaps, with a certainty before them that even a faint hope of remuneration could not be entertained rationally. We have seen them at patients' bedsides, day and night, not merely bestowing their skill freely, without thought of a fee, but supplying from their stores requisites for invalids, such as nourishing food and medical comforts, and wine. Humanely reckoning we have seen many a life saved through, and by, their philanthropic ministrations. There is, indeed, a life of true charity, inspired largely by noble impulses, emanating in a noble profession."

I find *The Simla News* and the *Mofussilite* siding very strongly with the above views.

Yours &c., W. C.

CALCUTTA, 4th August 1898.

THE ARMY MEDICAL STAFF IN ITS NEW COLORS. HOW DO THEY LOOK?

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The Warrant has been issued that has changed the designation of the Army Medical Staff to that of the Royal Army Medical Corps, and given its officers substantive instead of relative rank. We are informed that even

Her Majesty's interest was so far enlisted as to have prompted her to dub the Corps as Royal. There ought accordingly to be great jubilation in the ranks of the corps thus honored, and it ought to give them immense satisfaction that, by combined and persistent action they have forced the authorities to recognise the fact that changes in the corps were imperative.

I am not a pessimist, but I confess, I view with suspicion the acts of Government affecting the Medical Department of the Empire generally.

If you will permit me, I would essay a forecast of how the new Warrant is likely to operate, but before doing so, it will be instructive, I think, to take a retrospect of things medical.

When some eight years ago, the Subordinate Medical Department moved for a change of designation and an increase of salary, the old heads amongst us prophesied "You'll get the name, but not the pay." How far the prophecy has been fulfilled, your readers know.

A little previous to this, the Campdown Commission elaborated its double-barrelled and magazine rifle titles for the decoration of the Army Medical Staff. There was great jubilation then, but mostly amongst the junior officers or rather the unthinking section of them. The hated appellation 'Doctor' was to be discarded forever from the army; top-boots and spurs became very much in vogue at the morning hospital visit. TOMMY ATKINS was more frequently called to order for his non-observance of the precise form of respect due to a Surgeon-Captain, and interrogated as to whether he would speak or act in the same manner before an officer of his corps &c., &c. At times and places, even the qualifying designation of 'Surgeon' got into the habit of being dropped. I remember the amused smile of a combatant officer who entering a hospital one day asked for the "Doctor" and was informed that he would find "the Major in the office." To short serviced fitting TOMMY ATKINS, the compound titles as we all know are a perpetual source of embarrassment. The "Doctor" the "Major Doctor" the "Captain Surgeon" the "General Doctor" are shibboleths in T. A.'s mouth that he never fails to stammer over. It soon became evident to even the most junior officer of the Army Medical Staff that they had received the shell without the kernel, and a very rotten shell at that. They gained nothing and I think lost much. Assumption of the prestige of a rank that only existed on paper and excited universal ridicule, "got up the backs" of the combatants, and brought matters to such a degree of tension that the provision of the present Royal Warrant will hardly relieve, indeed is likely to accentuate. This is the retrospect, now for the forecast.

The doctors having obtained substantive rank and having been made a Royal Corps, how will they stand in the future, as regards their relations with combatant officers? A Lieutenant of the Royal Army Medical Corps becomes a Captain after three years' service, whilst it takes a combatant officer, three or four times that period to attain the same rank, and perhaps another decade and a half to attain his majority. Here is a state of matters anomalous enough to excite more than comment.

Rank carries power and influence everywhere in the Army, but what power or influence can it confer on a body

of non-combatant officers, whose value in the Army in peace time or in war must of necessity be very small? Officers of other departments, like the Engineer, Commissariat, Ordnance &c., are all combatants and should, on occasion arise, can take their places as leaders of a fighting post. The Medical Officer through no fault of his, is nevertheless unfitted to fill such a post.

The organisation of other departments is such that their officers are rarely, if ever, thrown into situations that render the precedence of rank a matter for consideration. One instance will suffice to show what I mean. A Captain commands a post or station; all the officers present are his juniors, with the exception perhaps of the medical officer, who may be senior in rank and service, but he must obey, where he ought to command.

Unlike other Departmental officers, the medical officer is brought into close and daily relation with the soldier, but his authority over the latter is virtually nil, and the soldier knows it.

Viewed from any standpoint, it appears to me that the officer of the Royal Army Medical Corps has gained virtually nothing over the officer of the Army Medical Staff, and that his future is beset with tribulations worse than those of the past. He has set himself up in opposition to a hierarchy with a prestige too firm to be shaken, too jealously guarded to be lightly attacked, and a hierarchy with a history as old as England herself and with almost absolute power at its back. Until the Medical Officer can take his place as a combatant leader, his contention to stand on the same platform as the other officers of the British Army will only be met by opposition, or at the most, by concessions that it would appear do not satisfy the ambition of the Medical Staff.

Yours &c, SUR.

—:—:—

MILITARY ASSISTANT SURGEONS, A PROTEST.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Verily we have often to be as watchful of the tender solicitude of our friends for our welfare, as of our enemies; and our friend (in your last issue) in a shortsighted attempt to keep pace with the times in demanding for us real military rank, would fain undo the sole achievement of our struggles for the last nine years.

Let us consider a moment what it is, he proposes. He would renounce our present honorable designation of Assistant Surgeon with all that it implies and the splendid history attaching to its past—for what? For that of conductor forsooth? And why? Because in his opinion, and that of a few others, the latter designation implies a solid and recognised military rank!! Pitiable delusion! I can hardly believe that he has ever given the subject serious consideration.

Why, let me ask him, should the designation of conductor any more than that of Assistant Surgeon imply any military rank? Merely because it is older! With as good reason might these same departmental conductors be indignant that they were not designated, as in the Royal Navy, Boatwains, carpenters and head cooks! Logically this is the outcome of our friend's contention.

As a matter of fact the title 'conductor' is no more a military rank than any of the others quoted. No one

could by any stretch of imagination impart a military ring to the sound.

It is common to, and therefore suggestive of, cabbles, 'Bus and Railway guards, just as ours is that of the honorable profession of medicine. As far as the Army is concerned they are each and all merely equivalents, arbitrarily fixed, on the creation of a new class in the Army, intermediate between the recognised Commissioned and Non-commissioned ranks and collectively egypt "Warrant officers"—a mere way out of a difficulty created by the necessity of gilding the soldiers' prospects without actually conferring the commission on them, when employed in responsible duties other than those appertaining purely to the 'rank and file.' But it is invariably employed now officially as a standard of comparison, I may be told. Quite so. Nevertheless merely by virtue of its more ancient date, and the greater familiarity of officers consequently with the status the term implies. Now however, all officers are fairly acquainted with the status of Assistant Surgeons as Departmental Warrant Officers, yet when a question of seniority arises a reference to a standard classification of Warrant Grades becomes necessary, and this is to hand in the old classification of Conductor and Sub-conductor with which they are familiar.

How our enemies, over whom we have so lately triumphed after a severe and protracted struggle that at one time threatened a crisis, must laugh in their sleeves at this wretched diversity of opinion among us. Well might they chuckle over the belief that they have only to give us rope enough to see us hang ourselves.

We hold an honorable designation to which we have proved our right and title. For God's sake, let no mania deprive us of it!

I cannot believe your correspondent's voice is representative of any material section of us; and it is only our unfortunate and characteristic apathy I am sure, that prevents you being flooded by indignant protests against his absurd proposals.

Yours &c, AN OLD ASSISTANT SURGEON.

—:—:—

MEDICAL SLANDERERS.

TO THE EDITOR, "INDIAN MEDICAL RECORD"

SIR,—Never before has there been such a crushing necessity for real sledge hammer hitting at certain official scandal-mongers who spitefully prostitute the prestige of their position by scandalising their non-official brethren before the patients of the latter, when they chance to come under official treatment in our public hospitals. Allow me to record two instances of dishonorable and unprofessional conduct on the part of an official in a hospital in this city.

I. A patient who had been under the care of one of the leading non-official practising physicians of Calcutta, was compelled to go into hospital because of the increasing medical and nursing fees of his case, which amounted to over fifty rupees a day. After a few days residence in the hospital, he asked the doctor if he would kindly have a consultation with his own private physician. The official doctor got very angry and said "Certainly not, do you think I am going to consult with a coolie doctor." Allow me to add that this so-called

oculist doctor is a British M.D. and enjoys a most lucrative practice in the city.

II. Another private physician had one of his cases enter the same hospital. The same official doctor when reading over the notes of the patient's case, remarked "So you were under Dr. _____'s treatment. No wonder you got worse, you should have gone to a government doctor."

That our public hospitals are badly managed, that patients resorting to them are treated with scant courtesy and marked neglect by men, who though heavily subsidised, scamp their official duties in their mad rush after private practice, are facts to which every non-official European who has unfortunately been compelled to resort to the public hospitals for treatment, is able to testify to, but that these medical officials should have recourse to the unmanly and cowardly methods which they employ to injure the professional reputation of their non-official brethren, is conduct that cannot be too publicly and too strongly denounced in the interests of the public, our hospitals and the credit of the medical profession itself.

Yours &c., E. F. G.

CALCUTTA.

A POOR MAN'S VERY HARD CASE.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Will you kindly allow me a little space in your far famed Journal, as I wish to have my case published and to see whether there is any redress for me.

I am a Military Hospital Assistant and was doing duty under Surgeon-Major E. Cretin in 14 and 131., stationed at Jhansi. On the 19th of January 1897, I was disgracefully abused by him without any cause. On bringing this to the notice of the Lt.-General Commanding the Forces, at Naini Tal, on the 14th June 1897, I was told that I could leave the Service at once on my refunding all salaries received by me since July 1891, or that I could leave on the 1st July 1898, on the completion of seven years' service, without incurring any penalty.

I accordingly at the time specified applied for my discharge, but my request was not granted. On repeating the application however, I was merely ordered to appear before a Medical Board.

The privilege leave which I was obliged to apply for owing to a very pressing private matter, and to which I was fully entitled, was also refused me. With reference to the Medical Board I fail to see any necessity for my appearing before it, my term of service having expired on the 18th July 1898, as I had already given notice. On the 15th of that month I resigned my situation, after twenty years' service.

I have also to state that I have been put to further trouble in being ordered about to various stations, on various duties, having had no less than a dozen transfers within a year. Besides this, I was not fully recompensed for my travelling expenses. For example, in the course of my last transfer from Golaghat to Kohima, I actually expended Rs. 40 for cart-hire as no coolies were available, and all I received from Government was Rs. 15 only, causing me the loss of Rs. 25, the whole of my monthly pay on a single transfer, to say nothing of my out-of-

pocket expenses on the journey. Thus I have lost both money and health, and in spite of all this, my resignation has not been accepted. I therefore most respectfully beg that you will use your way to bring my hard case to the notice of the Government of India.

Yours &c. Z. J. K.

Hospital Assistant.

MANIPUR.

PAYING THE DEAD TO ROB THE LIVING, WHO'S TO BLAME?

TO THE EDITOR, "INDIAN MEDICAL RECORD"

SIR,—From the general orders, Military Department, Simla, dated 24th June and 1st July 1898, it would appear that the medical subordinates therein promoted, lose a day's pay each as the men for whom the promotions are made, were born on the 20th and 8th September 1842, respectively, and the promotions are made from the day after, namely 21st and 9th September. Can you as any of your readers explain this error? A man born on the 20th Sept. 1842, completes his 56th year on the 19th Sept. 1897, and heretofore the promotions have been made with this in view, whence the necessity for change! Then again do the men on retirement commence to draw retired pay on the 20th and 8th Sept. or from the 21st and 9th. I take it that the date of retirement would be the date of birth, 20th and 8th, and retired pay, if so all these subordinates have lost a day's pay which goes into the government's pocket, as the men retired have been permitted to remain on for a day, *sans raison*.

Yours &c., BRIGGARD.

TREATMENT AND OPINION WANTED.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—What is the best treatment to adopt in cases of horny feet, which very often crack and bleed, and then become so painful, that the patient is unable to walk or even wear a shoe.

I have treated such cases with warm water immersion, shaving of the corns, application of KEMP's corn and wart remover, but without effect.

The last named seems to remove the corns, but when left alone for say about a month, they grow again and get as bad as ever.

I have known KEMP's corn and wart remover to effectually remove small corns on the toes.

Yours &c., MEDICUS.

BASIN, 23rd August, 1898.

Book Reviews & Medical Trade Notices.

THE DISORDERS OF DIGESTION IN INFANCY AND CHILDHOOD.

BY W. SOLTAN FENWICK, M.D., B.S., M.R.C.P.

Physician to Out-patients at the Evelina Hospital for children, London, &c.

(Publisher: E. K. LEWIS, London, pages 378, demy 8vo., Price 10s. 6d.)

THE above forms the second of a series of monographs upon Diseases of the stomach. The first part of the book is devoted to the physiology of digestion in early life, and the various diseases which are apt to arise from the neg-

part of the fundamental laws regulating infantile diet and hygiene. The remainder of the work is occupied with a description of the diseases of the stomach which are encountered during the period of childhood, while the appendix contains some account of the methods employed in the chemical examination of the contents of the stomach, &c. A copious index completes this useful work.

THE DISEASES OF THE LUNGS.

By J. K. FOWLER, M.A., M.D., F.R.C.P.

Physician to the Middlesex Hospital and to the Hospital for Consumption and Diseases of the Chest, Brompton, &c., and R. J. GOODLEE, M.A., F.R.C.S., Fellow and Professor, University College, London, Surgeon to University College Hospital and to the Hospital for Consumption and Diseases of the Chest, Brompton.
Surgeon in ordinary to
H. M.'s Household.

(Publishers: LONGMANS, GREEN and Co. pp. 715.
Price £1.5-0)

ALTHOUGH not aspiring to the position of an exhaustive treatise on the diseases of the lungs, this valuable work, the joint production of a Physician and Surgeon, presents a continuous picture of the Medical and Surgical aspects of Pulmonary disease, Bronchitis, Asthma, Pneumonia, Pulmonary Tuberculosis and the other forms of Lung Disease are fully dealt with, while the introduction of the anatomical chapter is calculated to prove very useful. The work is excellently got up, being bound in dark grained cloth, with red edges.

MANUAL OF OPERATIVE SURGERY.

By H. J. WARING, M.B., M.D., D.Sc., F.R.C.S.,

Demonstrator of Operative Surgery, St. Bartholomew's Hospital, London, &c., (pp. 661).

(Publisher: Y. J. Pentland, Edinburgh and London.)

THIS work which was written with the object of serving as a text-book for the classes in the Operative Surgery Department of St. Bartholomew's Hospital, provides a complete handbook for the use of students. For their benefit is added a description of operations which cannot easily be performed on the dead subject. Most of the illustrations—and there are over four hundred in number—have been prepared specially for the book, which, quite apart from its own excellence, has the author's name as a further recommendation.

DISEASES OF WOMEN, A TEXT BOOK FOR STUDENTS AND PRACTITIONERS.

By J. C. WEBSTER, B.A., M.D., F.R.C.P.

Demonstrator of Gynecology, McGill University Montreal, &c., &c.

(Publisher: J. PENTLAND, Edinburgh and London.)

WITH a view to give prominence to the scientific basis of each subject under consideration, the admirable work before us bestows the most careful attention to modern researches in sectional and dissectional anatomy, histology, embryology, comparative anatomy, pathology, and bacteriology, in so far as they bear on the diseases

of women. Clinical features in their widest relationships are studied, and assigned their proper proportional values, while in the case of therapeutic measures not yet thoroughly tested, extreme caution is insisted on. The illustrations from the author's original drawings, will be found to possess a high teaching value.

(1) IODOFORMOGEN; AND (2) TANNALBIN TABLETS.

(B. KUHN, 36, ST. MARY-AT-HILL, E. C.)

THE idea of combining iodoform with albumin, giving rise to a compound which has been called Iodoformogen, is ingenious and one presenting certain distinct advantages. Thus iodoformogen has little or no smell, is non-hygrosopic, and occurs in the condition of a fine powder, which it is said does not "lump." In short, iodoformogen would appear to be much superior for the purposes of dressing wounds to iodoform itself, as while exhibiting the antiseptic properties of iodoform, it permits of more uniform dusting, the grains clinging more intimately to damp surfaces than is the case with iodoform. Tannalbin is now well recognised as a useful but non-toxic intestinal astringent. It is particularly serviceable for checking diarrhoea. This is to be attributed to the fact that while it is insoluble in the gastric juice, producing no disturbance in the stomach, yet it dissolves slowly in the intestinal fluids producing an astringent effect. The compound is prepared from albuminate of tannin by exposure of the substance to a temperature of 110° or 120° C. for five or six hours. The tablets contain five grains of the compound and they afford a very convenient means of administering it.

EFFICACIOUS GERMAN PREPARATIONS.

FARBENFABRIKEN VOM FRIEDR. BAYER & CO. ELBERFELD (GERMANY).

IT is a matter of some difficulty to select for special mention any of the valuable preparations manufactured by this Company. Amongst others we may name Iodothyrene which not only contains the active principle of the thyroid gland, but also a fixed amount of Iodine compound. It has proved of inestimable value in myxœdema, obesity, psoriasis, and eczemas of sorts and may be taken with equal benefit by adults and children.

Another preparation of theirs is Iron-Somatose which is a specific for chlorosis and anæmia, as it contains in an easily soluble form albuminous substances combined with Iron.

Milk-somatose which contains the albuminous matter of milk combined with tannic acid is of great service in chronic disorders of the digestive apparatus.

There remain some other preparations of equal merit, but want of space precludes us from noticing them in this issue.

NEURALGIA.

MANY cases of this disease are due to anæmia, which is generally associated with indigestion. The employment of Kassa (Stern's Cascara Aromatic) Hæmoferum-Stern's, and Wine of Cod Liver Oil will be found of a great advantage in the treatment of this class of cases.

Solatol, pleurodynia and other forms of neuralgia yield quickly to this treatment.

Government Medical Gazettes.

GOVERNMENT OF INDIA.

To be Brig.-Surgn.-Lieut.-Col.

MADRAS ESTAB.—Surgn.-Lieut.-Col. Thomas James Hackett Wilkins, 14th July, 1898.

Surgn.-Lieut. to be Surgn.-Capt. 29th July 1898.

BENGAL ESTAB.—John Stephenson, M.B.; Frank Needham Windsor, M.B.; Walter Barrie Turnbull, M.B.; Ernest Edwin Waters, M.B.; Asner Leventon; Philip Francis Chapman, M.B.

MADRAS ESTAB.—Frederick Linton Blenkinsop, M.B.; Edmund Morris Illington; Thomas Edgar Watson, M.B.; Charles George Webster.

BOMBAY ESTAB.—Alfred Hooton; Arthur Frederick William King; Robert Fraser Standage; Andrew Armstrong Gibbs; Henry Alfred Forbes Knapton.

The undermentioned have Retired from the Service:—

Brig.-Surgn.-Lieut.-Col. David Douglas Cunningham, C.I.M., Bengal Estab. 26th June 1898.

Surgn.-Lieut.-Col. Oswald Baker, Bengal Estab. 6th July, 1898.

Surgn.-Lieut.-Col. John Francis Fitzpatrick, M.D., Madras Estab. 9th July 1898.

Surgn.-Lieut.-Col. Joseph Backhouse, Madras Estab. 1st July 1898.

Surgn.-Major L. A. Waddell, M.B., I.M.S. (Bengal), Cheml. Exam. and Prof. of Chemistry, Med. Coll. Calcutta, special leave for six months, from 21st July 1898.

Mily. Asst. Surgn. J. J. A. Brachio having passed his dept., exam., is entitled to the enhanced rate of pay of his class, from 14th Dec. 1897.

The services of Mily. Asst. Surgn. E. A. St. Romanine (Bengal), are placed at the disposal of the Agent to the Govt. Genl. in Rajputana.

The services of Mily. Asst. Surgn. P. McCarthy (Bengal), are placed at the disposal of the Govt. of Burma.

BENGAL GOVERNMENT.

Surgn.-Capt. R. Bird, Resident Med. Officer, Med. Coll. Hosp., Calcutta, to act as Prof. of Physiology, Med. Coll. Hosp.

Surgn.-Capt. F. C. Clarkson, to act as Civil Surgn. of Nadia until further orders.

Brig.-Surgn.-Col. W. H. Gregg reported his departure from India, 26th July 1898.

Asst. Surgn. J. J. A. Brachio to act as Asst. Apothecary to the Med. Coll. Hosp., Calcutta.

Asst. Surgn. Surut Lal Basu, to do super. duty Med. Coll. Hosp.

Asst. Surgn. Behari Lal Pal, Offg. House Surgn., Ezra Hosp. to do duty Presy. Genl. Hosp.

Asst. Surgn. Kali Mohun Sen, doing super. duty Med. College Hosp. to do duty, Presy. Genl. Hosp.

Asst. Surgn. Jogueswar Mukerjee, to do super. duty, Med. Coll. Hosp.

Asst. Surgn. Kasi Nath Ghosh to do super duty Med. Coll. Hosp.

Asst. Surgn. Satis Chandra De, Bhowanipur Hosp. to be Teacher of Medicine, Pathology and Hygiene, Orissa Med. School, Cuttack

Asst. Surgn. Nripendra Nath Basu, House Surgn., Eden Hosp., Calcutta, to the Med. charge, Bhowanipur Hosp.

Asst. Surgn. Mohendra Nath Das to do supy. duty, Med. College Hosp.

Asst. Surgn. I. Burnett, Mifflord Hosp., Dacca, to be Insp. Med. Officer at Mairwa, Bengal and N.-W. Ry. Saran Dist

Asst. Surgn. G. T. Milchem, Genl. Hosp. to act at the Mifflord Hosp., Dacca.

Asst. Surgn. W. Clarke, Offg. Asst. to the Surgn. Supy. Presidency Genl. Hosp., Calcutta, to act at the Howrah Genl. Hosp.

Asst. Surgn. W. Sherrington, Insp. Med. Officer, Plague Observation Camp, Mairwa, to act as Asst. to the Surgn. Supy. Presidency Genl. Hosp., Calcutta.

Asst. Surgn. H. G. C. Mills, acted as Asst. to the Surg. Supd. of the Presy. Hosp. from 31st March to 4th April, 1898

Surgn.-Capt. J. G. Jordan reported his departure from India, on furlough, 2nd Aug. 1898.

Surgn.-Capt. W. J. Rudmann acted as Civil Surgn. of Midnapore from 26th June to 4th July 1898.

The services of Asst. Surgn. Chander Kumar Dutta are placed temporarily, at the disposal of the Chief Commr. of Assam Asst. Surgn. Chuni Lal Bora, Cheml. Exam. to Govt. and Asst. Prof. of Chemistry, Med. Coll. Calcutta to be in charge of the current duties of the office of Cheml. Examiner to Govt. and Prof. of Chemistry, Med. College, Calcutta,

PUNJAB GOVERNMENT.

Brig. Surgn.-Lt.-Col. W. A. C. A. Roe, I. M. S. (Bengal), Sany. Commr., Punjab, furloughed out of India for one year, from the 18th Augt. 1898.

Surgn.-Major C. J. Bamber, I. M. S. (Bengal), Civil Surgn., Rawalpindi, to officiate as Sany. Commr., Punjab.

Surgn.-Major T. E. Mulroney, Civil Surgn. Amritsar, reported his departure from Bombay 18th June, 1898.

Surgn.-Lieut.-Col. D. O' C. Rye, Inspr. Genl. of Civil Hosp. Punjab, made over charge to Brig. Surgn. Col. W. A. C. Roe, Sany. Commr., Punjab 10th. Aug. 1898.

Surgn. Lieut.-Col. A. W. Mackenzie, resumed charge Civil Med. duties of Abbottabad, 30th July, 1898.

CENTRAL PROVINCES GOVERNMENT.

Surgn.-Col. G. Hutchinson, M.D., I. M. S. (Bengal), Admin. Med. Officer and Sany. Commr. C. P. is granted privilege leave for three months.

The services of Surgn.-Capt. A. G. Hendley, I. M. S. (Bengal), are replaced at the disposal of the Chief Commr., C. P.

Hosp. Asst. Imam Khan, Jail Hosp. Chanda, held charge Police Hosp. from 4th June to 31st July 1898.

Hosp. Asst. Surendranath Chakravarti, to do duty under Civil Surgn., Nimar.

Hosp. Asst. Surendranath Chakravarti, doing duty under Civil Surgn. Nimar, to do duty under Civil Surgn., Sangor.

Hosp. Asst. Vithal Raghoba Landa, doing duty under Civil Surgn. Jubbulpore, to Bijragogath Branch Dispy. Jubbulpore dist.

Hosp. Asst. Ashraf Husain, to do duty under Civil Surgn., Jubbulpore.

Hosp. Asst. Bapu Madho, doing duty under Civil Surgn. Raipur, to take charge of the Police Hosp., Sambalpur, from Hosp. Asst. Ganesh Parshad.

Hosp. Asst. Ahmadulla Khan was employed on Famine duty under the P. W. D. Sangor, from 1st April 1897 to 31st Augt., 1897. He did duty under Civil Surgn., Sangor, from 1st to 20th Sept. 1897, and was again on Famine duty under P. W. D. at Sangor from 21st Sept. 1897 to 16th Nov. 1897.

Hosp. Asst. Abdullah held charge, Pandaria Poor-house, Bilaspur dist., from 13th July to 8th Sept. 1897.

Hosp. Asst. Rhonda Lal, on plague duty at Sangor, is reduced to the grade of 3rd Class Civil Hosp. Asst. by order of the Chief Commr. from 31st May 1898, to do duty under the Civil Surgn. of Sangor.

Hosp. Asst. Mantasullah Khan, doing duty under the Civil Surgn. of Jubbulpore, to the Jail and Police Hosp., Mandla.

Hosp. Asst. Amin-ud-din, to the Shahpura Dispy., Mandla Dist.

Hosp. Asst. Chandra Bhan, to Sangor for plague inspn. duty.

N.-W. P. AND OUDH GOVERNMENT.

Asst. Surgn. Masha Allah Khan, Lecturer, Materia Medica and in charge of Thomason Hosp. Agra, privilege leave for one month from 3rd Aug. 1898.

Asst. Surgn. E. H. Thomas, M.B., L.B.C.P. and S. (Edin), L.F.P. and S. (Glasgow), L.M., on being relieved of the acting duty as Lecturer on Materia Medica and in charge of Thomason Hosp. Agra, is reappointed to same duty.

Asst. Surgn. Behari Lal Pande, from Sadar Dispy. at Khasi to that at Basti.

Asst. Surgn. Hara Kanta Baujeri, from Sadar Dispy. at Basti to that at Kheri.

Asst. Surgn. Tarak Nath Ghose, Sadar Dispy., Beharanpur, privilege leave for one month,

Asst. Surgn. Jogendra Prasad Sanyal, Travelling Med. Inspr., Cawnpore Circle, to Khurja Dispy. Bulandshahr Dist.

Asst. Surgn. Dalip Singh Kotwal, on Plague duty, Hardwar, to Sadar Dispy. Etah.

Asst. Surgn. Gauri Lal, on Reserve duty at Lucknow, to Plague Inspn. duty, Jhansi.

Hosp. Asst. Lakshmi Narain, Jail Hosp. Khari, held charge Sadar Disp. at that Sta. from 24th to 31st July 1898.

Asst. Surg. Shashi Bhushan Banerji, Travelling Med. Insp. Ghaziabad Circle, to Platford Insp. duty, Ghaziabad.

Asst. Surg. Chusan Singh, from Plague duty, Ghaziabad, to Reserve duty, Agra.

Asst. Surg. Gauri Lal, Travelling Med. Insp. Allahabad Circle, to Reserve duty at Lucknow.

Asst. Surg. Gobind Chandra Banerji, from Plague duty, Muttra, to that at Hardwar, Saharanpur Dist.

BURMA GOVERNMENT.

Surgn.-Capt. Kanta Prasad, M.B., assumed charge duties of Civil Surgn. Sagaing, 14th July 1898.

Surgn.-Capt. C. E. Williams, M.B., assumed charge duties of Resident Med. Officer, Genl. Hosp. Rangoon, 22nd July 1898.

Asst. Surgn. Maung Chit Tun, assumed charge Genl. Hosp. Moumein, 15th July 1898.

Hosp. Asst. Nasaral Haq, on transfer from the Genl. Hosp. Mandalay, assumed charge, Town Disp. Mandalay, 25th July 1898.

Hosp. Asst. Rajchunder, Kur, assumed charge Genl. Hosp. Mandalay, 25th July 1898.

Hosp. Asst. Maula Baksh, assumed charge Outpost Hosp. N'Krang, Myitkyina dist. 9th July 1898.

Hosp. Asst. Chowdri Mailla Baksh, assumed charge Civil Hosp. Mergui, 19th July 1898.

Hosp. Asst. Radhanath Singh, assumed charge, Mily. Police Hosp. Mogaung, 21st July 1898.

Hosp. Asst. B. B. Chukerbatty, three months' privilege leave from 21st July 1898.

Hosp. Asst. Makhan Lal Warma, assumed charge Outpost Hosp. Kynhla, Shwebo dist. 24th July 1898.

ASSAM GOVERNMENT.

Asst. Surgn. C. R. W. Bancroft, whose services have been placed at the disposal of the Chief Commr. is posted to Tura to be Civil Med. Officer, Garo Hills.

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Rs. 1 for subscribers and Rs. 2 for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTHS.

BORAH.—On the 8th of Aug., at Silchar, the wife of Surgn.-Lieut.-Col. S. Borah, I. M. S. of a daughter.

WOOLBERT.—On the 9th Aug., 1898, at Fair View, Landour, the wife of Surgn.-Major H. B. Woolbert, I. M. S., of a daughter.

MARRIAGES.

BOWIE—CHICHELE-PLOWDEN.—On the 20th July at Christ Church, Lancaster Gato, Alex Bowie, M.D., C.M., L.R.C.P.E., etc., of 40, Hartford-street, Mayfair, eldest son of John Bowie, M.D., L.R.C.P.E., to Henrietta A. Chichele Plowden, only daughter of the late Captain H. Chichele Plowden, Bengal Staff Corps.

BROWNE—BRADSHAW.—On the 21st July, at St. Giles's Church, Camberwell, S.W., Depy. Surgn.-Genl. James Browne, M.D., Bengal Army (Retired), to Charlotte (Lottie), daughter of the late Christopher Bradshaw, of Grove Park, Denmark Hill, S.E.

DEATHS.

JOHNSTON.—On the 24th July, at his residence, Edendariff, Cheltenham, Surgeon-General William Johnston, M.D., late Madras Army, aged 81 years.

MURRAY.—On the 27th July, at Cloughbane, Sheringham, John Murray, M.D., Surgn.-Genl., aged 88.

BEATSON.—On the 29th July, at Cromwell-road, Earl's-court, Surgn.-Genl. John Fullerton Beatson, M.D., C.I.E., aged 81 years.

CARDEW.—On the 17th Aug., at Murree, of meningitis George Schuyler Cardew, Major. R. A. M. C. son of the late George Schuyler Cardew, Insptr. General of Hoops, Bengal Army.

JELOVITS.—On the 25th August, at 8-30 P.M., at 84, Durrantollah Street, Sophia, the dearly beloved wife of Dr. T. L. Jelovits, aged 63 years. Bombay and American papers please copy.

WALSH.—On the 13th of August, at Berhampur, Bengal, Mary, the wife of Surgeon-Major J. H. Tall Walsh, of typhoid fever.

NOTICES TO CORRESPONDENTS.

P. C. (Yeotmal).—We shall always look upon you as a most valued helper and associate.

W. M. O. *Provident Fund*.—Surgeon-Captain Wade has not yet submitted a statement of account of the Fund, nor has he handed over the monies to its credit to the Treasurer of the Indian Medical Association as he is in duty bound to do. Surgeon-Major Hodgkins, the Treasurer, is at present away on leave, on his return, it is hoped that Surgeon Captain Wade will immediately make the necessary transfer of documents and funds.

A. F. F. (Daman).—Thanks for your article and note which will receive attention in our next issue.

D. F. (Nagpur).—Kindly send in an appeal to the President of the Indian Medical Association, backed by a printed and attested copy of your testimonials. Give a detailed statement of your services as an Assistant Surgeon; and if possible, obtain letters from a few Medical Officers who know you, recommending your appeal. The Council under such circumstances will be pleased to support your case.

B. S. R. (Duggavati).—The title Doctor as a prefix, can only legitimately be used by medical men and women possessed of the degree of M.D., or M.B. It is however a title that is courteously allowed to all medical men and women who hold diplomas, other than university degrees.

J. H. M.—Your paper meets with attention in this number.

W. W. B. (Landour).—Your query is already answered in this issue.

B. P. (Dehree on Sone).—For the treatment of mercurials, try arsenic internally and inunctions of zinc ointment.

R. S. (Goonia).—We have received no intimation concerning medical subordinates recommended for promotion and other honors for the Tirah campaign.

D. D. (Jhansi).—Arm yourself with written testimony concerning your abilities and character, and the Council of the Indian Medical Association will be pleased to assist you in any way in its power.

Eden Hospital.—The note made on the slip given to the out-door patients you refer to, is absolutely incorrect, the patient was subsequently, within twentyfour hours, carefully examined by two practising physicians, who totally disagree with the opinion expressed in the note.

Deo Lal.—A further reference has been made to the Indian Medical Association by the C. P. Government on your case. Will you kindly forward at once to the Secretary, Indian Medical Association, a printed copy of the whole of the papers, which were submitted to Government regarding your appeal.

G. E. C. Civil Assistant Surgeons do not belong to the Apothecary class and they have never been so designated. There still exists a class of Civil Apothecaries in Madras, but this appellation will soon be abolished.

A. M. (Kashmir).—Many thanks for your valuable paper. It will appear in our next number.

Hospital Assistant Ram Dhari Sinha, Medical Officer, Civil Hospital, Abu Road, Rajputana, wishes it publicly known that he is not L.M.S., but L.T.M.S., (Patna).

ORIGINAL ARTICLES

NOTES FROM CLINICAL RECORDS OF THE
KASHMIR STATE HOSPITAL.

By DR. A. MITRA, RAJBAHADUR, L.B.C.P., L.R.C.S., F.C.S.

Chief Medical Officer, Kashmir.

Reported by PANDIT ANAND KOUL,

Personal Assistant.

(1895-96).

I. MEDICAL AND GYNECOLOGICAL.

In Kashmir the medical cases are now varied. Fevers and pneumonia take the lead. Of acute specific fevers, remittent fever is the most common. Three cases of typical typhoid were treated, one being a hospital assistant in Gilgit Transport Service. Four cases of small-pox were treated in the isolation ward of the Srinagar Hospital. Three children suffering from diphtheria were treated and all three died. Whooping cough often occurs in epidemic form; two such epidemics were observed during the year. Malarial fevers are by no means uncommon in July and August. Of constitutional diseases, rheumatism, acute and chronic, takes the lead. Purpura is a very common disease in Kashmir. It often occurs in epidemic form, and village after village is attacked with it. Many die from it. Diabetes is not common though I have met with many serious cases. With the generally used carbohydrate food one would perhaps expect greater prevalence of this disease but it is by no means so. Diseases of the throat are very prevalent, specially in Srinagar. Of respiratory diseases, acute croupous pneumonia is very common in winter. It is very fatal in Punjab. Pleurisy is also common. Phthisis is the one disease which is by no means common in Kashmir. Though a cold country, dwelling houses in Kashmir are generally very well ventilated, having several windows and openings. A large portion of the population live in boats. People generally lead an active outdoor life. The high altitude of the valley and its bracing mountain air are also factors which combine to make the Kashmiris comparatively free from tubercular lung diseases. Most of the cases, however, that I have seen, were among Zenana women who are shut in closed houses and take no physical exercise of any kind. The disease, however, is not uncommon among the Dogra sepoys, who coming from a hot country prefer to shut themselves up in barracks which are low and not well ventilated. Cardiac diseases are often met with. Digitalis and strophanthus yield the best results. Both mitral and aortic diseases were found yielding to digitalis. Dropsical cases in very advanced stages are received in Srinagar from the districts. The result of treatment is often satisfactory but more often not so. Endocarditis from gonorrhea and pericarditis from rheumatism are often met with. Asthma is a common complaint in Kashmir. One typical case of thoracic aneurism was met with during the year. Acute gastritis and enteritis are often met with. Dysentery is very common. Results with *ipocassuana sine emetine* were not encouraging. Diarrhoea is very common in summer, specially during the fruit season. Enlargement of the spleen among Kashmiris is not often found, while with the Punjabis and hillmen coming to Kashmir it is a common complaint. Renal diseases are

common. Bright's disease, disease of the spinal cord, general paralysis of the insane and other nervous diseases are frequently seen in Kashmir. Such diseases are mostly of syphilitic origin. I believe myxodema is by no means rare in Kashmir. Skin diseases of all kinds are frequently met with. During the year the proportion, of nervous, urinary and gynecological cases treated, to the total has remained identically the same as that of last year, the proportion of admissions of patients suffering from general diseases and diseases of the alimentary system has risen, that of the respiring diseases fallen, the last is no doubt due to the mild winter of 1895-96. Pneumonia did not appear with anything approaching the severity reached last year. In one gastric case autopsy was held. The seats of the perforating ulcers were, one in the middle of the anterior surface of the stomach the size of a 4 anna piece, and another of the same size in the posterior wall about the middle of the lesser curvature. In one case the ovary was removed for cystic growth with success. Exploratory incision was made in one case of salpingo-ovariitis in which the patient died. Minor gynecological operations of various kinds were performed. Pessaries were used in a large number of cases of displacement. A pessary was so favourite a mode of treatment that it was always paid for by the patient.

II. SURGICAL.

Chloroform was administered 564 times with no untoward results. For this great credit is due to House Surgeon, Amirbakhsh. Strictly aseptic methods are adopted in the Srinagar Hospital, and to this is due the satisfactory result in the treatment of surgical cases. I now use nothing but carbolic and for dressings zinc-oxydide & mercuric. Bone diseases afford a large number of cases for resection and gongzing. Tumours of various kinds were removed. Several amputations were done. Piles were very successfully treated. One case of strangulated hernia was operated on successfully. In a case of traumatic paraplegia I ventured to perform laminectomy, but the result was not satisfactory, though the life of the patient has been saved. In ophthalmic surgery, cataract and minor operations for pterygium trichiasis were done. For cataract iridectomy is done as a rule, though in some cases of soft cataract that procedure was dispensed with. I do not believe in SPANTON'S method for the radical cure of hernia. This operation was formerly done in Kashmir in large numbers. Many of these cases now come back as bad as before. In one such case I have recently done MITCHELL BANK'S operation. The sac was exposed and separated from the surrounding part, a ligature was applied round its neck high up. The sac below the ligature was removed. The inguinal ring was closed by silver sutures and left in position. Lateral lithotomy was performed in one case of stone. Several cases of severe head injury were received. In one, trephining was done for compression. Another case in which the brain protruded through a fractured skull, recovered.

(1896-97)

MEDICAL & SURGICAL.

1. During the year under report, 15,002 cases of venereal diseases were treated. I observe that venereal diseases are increasing in Kashmir, but a large number of cases now come under treatment in the earlier stages.

2. Rheumatic and skin affections mentioned in the report probably also include cases of venereal disease, though both these classes of diseases are very common in Kashmir.

3. As usual a large number of chest diseases were treated in Kashmir during the year. I am glad to record that with one exception all cases of acute lobar pneumonia recovered. Quinine in frequently repeated doses answered best. External application of creosote was tried in several cases for the reduction of temperature. The result was varying in some cases, among others in the case of one of our hospital assistants it proved very efficacious. Terebene was found to be a useful antiseptic expectorant. Guaiacol was largely tried.

4. I had to treat a large number of cases of heart disease, mostly cases with failing compensatory symptoms with dropy. Digitalis proved most useful, and with but one or two exceptions relieved them wonderfully. Diuretin was tried and proved efficacious in two cases, also caffeine, but the cases were few indeed that did not respond to digitalis.

5. I had a case of angina pectoris of pronounced type in a Bengalee compositor belonging to the Jail Press. He took ill on the road, and was so bad that he had to be carried to the hospital. Nitrite of amyl relieved the pain and a subsequent course of iodide was prescribed. The pain has not recurred.

6. Facial paralysis is very common in our out-door dispensaries. I noticed a case of facial paralysis with acute poliomyelitis. The lesion appeared to be nervous rather than myopathic. It bore some resemblance in distribution to the facio-scapulo-humeral form of muscular atrophy in infancy first described by DUCHENNE. The facial paralysis was complete. Febrile twitchings were present. I find facial palsy often connected with rheumatic causes and in such cases salicylate of soda acts like a charm.

7. I tried thyroid gland in some cases of goitre, which is a common disease in the Tral Tehsil in Kashmir, with no result whatsoever.

8. The months of June, July and August were marked by a great number of admissions into the medical ward of cases of fever, diarrhoea and dysentery. In March, April, November and December, pneumonia cases predominated, while in the winter months rheumatic cases, sore throat, bronchitis and pleurisy flourished. During the year affections of the respiratory organs have been rather over the average. The number of cases of acute and sub-acute rheumatism was nearly the same as that recorded last year.

9. A larger number of cases of *phthisis pulmonum* was treated during the year under report than before. The cases were all Punjabia and Gurkhas, sepoy and others. Tubercular disease of the larynx was present in two cases. In six cases out of 9, the disease was incipient and seemed to be arrested by treatment.

10. I do not think I had any case of typhoid, but I had several cases of remittent fever with diarrhoea.

11. There were 2 cases of appendicitis treated in the medical wards. They were cured without being transferred to the surgical ward.

12. In two cases the skull was trephined for depressed

fracture with very good results, and in another the mastoid was drilled for chronic suppurative discharge.

13. Chloroform was administered in 395 cases with no untoward results. One case took as much as 2 ounces and yet surgical anaesthesia was not produced. More chloroform was not given and the contemplated operation for haemorrhoids had to be abandoned. Strict antiseptics is observed in the treatment of surgical cases.

14. In some cases of wounds, sulphur was tried as a surgical dressing, but the result was not found satisfactory.

15. There was an epidemic of whooping cough in Srinagar during the year. Besides the usual remedies the following were used:—

(a) Bromoform.

(b) Ext. Castine Liq.

16. Three cases of diphtheria occurred in my out-practice. Two were treated with antitoxin received from Burroughs Wellcome and Co. All ended fatally. In two, pure sulphite of magnesia was insufflated.

17. Three scirrhus of the mammae were removed. One case we have lost sight of, but in two others recurrence has taken place. In one case I tried to follow the technique recommended by HALSTED.

18. It will be seen that only eleven cases of poisoning were treated during the year—only half the number recorded last year. There was no death from snake-bite.

19. The fatal cases in the surgical ward are thus accounted for—

(a) One case in which trephining was done for depressed fracture. The patient was admitted late, the pressure symptoms were pronounced and signs of meningitis supervened. The patient died from meningitis.

(b) Tracheotomy was performed in a child aged 5, in a late stage of malignant or diphtheritic tonsillitis. Patient was much cyanosed before operation.

(c) A case of chronic pleurisy with empyema in which incision was made. Patient was in a very low state and died of exhaustion, quite independent of the operation.

(d) A case of strangulated hernia died two hours after the operation. The case when admitted was moribund.

(e) Amputation above the knee was performed for a chronic suppurative disease of the knee-joint involving the whole of the tibia and extending down to the ankle. Before the operation the patient was in a very bad state with fever and abundant putrid discharges from the knee. In operation lay the last hope of life, but the patient died of exhaustion after eleven days.

(1897-98.)

I. SURGICAL.

1. The following interesting cases of injury of the skull were treated during the year:—

(a) A man was wounded on his head by a sword cut. The scene of attack was within a few hundred yards from the hospital. He, together with another man who was wounded in the lower jaw, and a woman, whose neck was totally severed, was brought into the hospital immediately after the injury. The patient was not fully conscious when he was brought into

the hospital, and was bleeding freely. On examination there was found a curved C shaped cut over the right parietal bone, $4\frac{1}{2}$ inches long. The bone was cut and the edges overlapped, the membrane was severed and the brain was found slightly protruding. The bleeding was first attended to. The depressed portion of the bone was removed by a chisel and strict aseptic treatment was observed. The result was, the patient left the hospital 27 days after, with a perfectly healed wound, and resumed his usual work.

(b) A mason fell from the roof of the Palace where he was working and sustained a fracture of the skull. It was a depressed fracture of the occiput with a central point of maximum depression and might have been termed a star-shaped depression. Symptoms of compression were pronounced and trephining was therefore performed. The patient was 40 days in the hospital and left it perfectly cured.

(c) Two cases of fracture of the base of the skull one following a blow on the head and another caused, by a fall, were treated. In one case, portion of the brain matter was found in the nose, and in another there was hemorrhage from the extended auditory meatus. Both cases proved fatal.

(d) A Punjabi ekka driver was admitted into the hospital in an unconscious state, having been thrown from his ekka near Pattan. Over the right parietal eminence was a jagged lacerated wound, beneath which was a depressed portion of bone. Trephining was performed, but the patient died 3 days after with symptoms of meningitis. In the necropsy the brain was found severely lacerated. There was a large quantity of extravasated blood over the right hemisphere.

2. A case of complete division of the lower jaw by a sword cut at the right-angle of the mouth running down obliquely to the ramus, was treated by wiring of the fragments by copper wire. The wound healed without any difficulty and the patient can now use his jaws freely.

3. Four cases of fracture of lower jaw, one of them caused by a native barber during the process of tooth extraction, were treated by splints and were cured. In these cases gutta-percha splints were used. I tried to use an interdental wire splint in one case but it did not prove satisfactory.

4. Seven cases of spine injury were treated, 2 contusions, 2 incomplete fractures, 2 fracture-dislocations, 1 undefined injury of the spine. Of these, 2 cases of fracture died in the hospital. The cases of contusion were cured: the other cases were removed by the friends of the patients, who at the time of leaving the hospital had all the spinal injury symptoms. The great difficulty in these cases was to keep the beds clean. They could not be kept in the general ward owing to the foul smell of urine.

5. One case of strangulated hernia in a sepoy was operated upon, but proved fatal. Twelve cases of hernia were reduced by taxis. Several cases of infantile hernia were seen.

6. A large number of internal piles were treated principally by incision by WHITEHEAD'S method.

7. There were three operations for cancer of the breast, in one the axillary glands were removed. I have 2 cases under observation, and in both there are signs of recurrence. An unusual case of scirrhus was seen involving both mammae, the whole of chest extending as far up as the neck, and as far down as the umbilicus.

8. In one case of congenital absence of the rectum, laparo-colotomy was performed. The pelvis was depressed and the proctodæum absent.

9. Castration was performed in a case of diseased testicles through syphilis. The testicle on removal was found to be a disorganized mass, infiltrated with pus.

10. Syphilis is responsible for fully 30 per cent. of our cases in the surgical ward. There are to be seen the primary lesion and its various manifestations, the secondary stage and its effects on the skin, the glands, the mouth, the throat and the eye. Then all the serious phenomena of the tertiary stage are seen in the bones, sclerosing osteitis, gummatous affection of the periosteum and medulla and necrosis. The infantile population suffer largely from protean lesions of inherited syphilis.

11. Carcinomatous growths over the abdomen and thighs were treated in large numbers. These are caused no doubt by the constant irritation of the live charcoal, used by the Kashmiris in an open wicker-cased pot called Kangri.

12. Nerve stretching has proved efficacious in severe and obstinate sciatica.

13. Disinfectants and Dressings.

(a) Iodoform is the most reliable agent in the treatment of wounds.

(b) In major operations, zinc-o-cyanide gauze and wool are the best.

(c) Irrigation is still practised and is found very useful during operation in keeping up a general asepsis.

(d) Glutol is a very useful healer of recent cuts.

(e) Chrystia is a very good substitute for gutta percha.

(f) There were no fatalities from chloroform. In two cases death was imminent, but inversion, injection of ether, together with artificial respiration saved life. Inversion, if early practised, is more useful than any procedure.

14. A larger number of cases of the diseases of the eye were treated during the year than the previous year, as being 11,381 against 8,227. It is satisfactory to note that with only one exception all my cataract cases yielded very good results. In eye operations strict antiseptic precautions are taken. Instruments are sterilized and antiseptic solutions freely used. Several cases of glaucoma were treated with myotics and iridectomy (done peripherally) and the result was fairly satisfactory. The disease was in many cases checked by the early use of a half per cent. solution of eserine.

II. MEDICAL.

1. The principal diseases treated in the medical ward were fevers, chest complaints, rheumatic and nerve diseases. Heart diseases, and cirrhosis of liver are also very common. Most of the heart cases seek treatment when compensation begins to fail, and treatment then generally fails to give satisfactory results. Tuberculosis in the lungs is not common among the Kashmiris most of

the cases treated being sepoys. Diabetes and kidney diseases are common, but locomotor ataxy, progressive paralysis of the insane and various neurotic disturbances, due to syphilis, are commonly seen.

2. The number of cases of acute lobar pneumonia admitted during the year, was much lower than during the previous year, and was in fact, the smallest number recorded since 1948.

3. There was an epidemic of influenza during the months of February, March and April. Forty-three cases were admitted suffering from the disease or from its sequelae, and 148 cases were treated for it in the out-patient department. In the indoor ward, only one patient died with pneumonia. Severe headaches, bronchitis, rheumatism and pneumonia were the principal complications. I found antikamnia very useful in the neuralgia of influenza.

4. One case in the medical ward was transferred to the surgical side, for resection of the rib for empyema.

5. One case of appendicitis proved fatal.

III. MEDICO-LEGAL.

Several cases of medico-legal interest were received during the year, among them the following are noteworthy :—

1. A case of death from gun-shot injury. The whole of the left parietal was fractured to pieces.

2. Complete section of the neck in a woman caused by a sword-cut.

3. Death from fracture of skull in two cases by blows from thick sticks.

4. Death from fracture of skull in a child, alleged to have been caused by the child being thrown forcibly on the floor.

5. Severe injuries by hot iron in a girl aged 12 with forcible coitus resulting in peritonitis and subsequent death.

—101—

THE URINE : CLINICAL TESTS : METHODS, AND SIGNS. *

BY A LOCKHART GILLIESPIE, M.D., F.R.C.P. ED.,
Medical Registrar, Edinburgh Royal Infirmary.

1. CASTS.

THE significance applicable to the presence of albumin and casts in the urine is regarded by PORTER (*Phila. Med. Jour.*, April 2, 1898, p. 587) as represented by the following :—

1. "Serum albumin." can no longer be regarded as a single proteid occurring in the urine.

2. The epithelium of the renal tubules excretes the various proteids passed in the urine.

3. That from these proteids the casts are formed.

4. That there are two classes of casts, one signifying structural alteration in the renal excretory mechanism, the other not doing so.

5. That casts without albumin are not so frequently found as albumin without casts.

6. That casts (not essentially co-existent with organic diseases) may be detected in almost every sample of urine centrifuged.

7. That a study of the kind of proteid and the size and forms of cast excreted in the urine, enables a diagnosis to be made with exactness as to the condition of the renal glands.

Further details of the correlation between the different forms of proteid and casts must be obtained from the original paper, as the subject is too widely treated to yield itself to brief abstraction.

(Berrie in the *Med. Rec.* N. Y., for January last year, called attention to the great frequency with which renal casts can be discovered in the urine, should the centrifuge be regularly employed. In fifty apparently healthy prisoners he detected casts in thirteen, albumin in twenty. He quotes SHATTNELL's 297 cases, arranged by decades from 20 years old to 90, and yielding from 23 to 100 per cent. of the urines with either albumin or casts, although apparently free from kidney disease.)

Litten (*Wein. klin. Wchnschr.*, 1891), as far back as 1891, pointed out that centrifugation of the urine demonstrated the presence of casts in cases believed, after application of the ordinary tests, to be absolutely free from any such bodies.

BARD (quoted in the *Centralbl. f. innere Med.*, Leipzig, 14th May, 1898) considers that granular casts vary with the intensity of the parenchymatous renal inflammation; if this is acute, the casts are consistent and opaque; with lessening acuteness the granular casts are fewer and more transparent. The diameter of the casts increase *pari passu* with the severity of the disease. After subsidence of the inflammation the casts become hyaline. Amorphous, colloid-looking casts denote the presence of sclerosis, and secondary atrophy following upon acute conditions.

Casts of a purely epithelial substructure seldom occur in parenchymatous nephritis, but betoken far more strongly some toxic irritation, leading to simple desquamation or inflammatory change of the epithelial cells. If, in assured cases of parenchymatous nephritis, no granular or colloid casts can be detected, although albuminuria still persists, it must be taken that the original inflammatory process has subsided, and that the proteid leakage is rendered possible by solutions of continuity between the epithelial cells.

HAINES and SKINNER (*Journ. Am. Med. Assoc.*, N. Y. 29th Jan. 1898) describe a new method of detecting the presence of casts in the urine. The older method of subsidence, and the later method by the use of the centrifuge, have each their advantages and disadvantages. Subsidence alone allows of the use of large amounts of urine, the centrifuge only of small quantities; subsidence often fails to give, the centrifuge always gives a compact precipitate. Combination of the two methods, as devised by the authors, leaves little or nothing to be desired in the detection of casts. They pour 250 c.c. or more of the urine into a sterilised glass percolator, add a gramme or two of chloral hydrate dissolved in a few c.c. of distilled water to retard decomposition (? fermentation), cover with a glass plate, and set aside for eighteen or thirty-four hours. Then the lower portion, containing any sediment, is drawn off through the ordinary tube, which opens into the bottom of the percolator, and is centrifuged. (The combined use of subsidence and centrifugation is by no means original, and has been practised

* Reproduced from the *Edinburgh Medical Journal* by request.

as of self-evident value for some time in this country; sedimentation being allowed to occur in tall vessels, and the precipitate pipetted off into the centrifugaliser tubes.—A. L. G.)

2. TO OBTAIN THE URINE SEPARATELY FROM BOTH KIDNEYS.

In the same number of the journal last referred to, HARRIS describes and figures an instrument by which the excretion of the individual kidney can be separately obtained from persons of either sex. It can, in truth, seldom prove of value in medicine, but reveals important facts as to the *status præsens* of the kidney on whose neighbour it is proposed to operate. The instrument is in the form of a double catheter in a common sheath, each catheter separately moveable longitudinally. The proximal end is curved in a similar way to a male sound, while the distal end is curved in the same way and in the same plane, indicating the exact position and direction of its prototype. Where the distal curve meets the straight portion, the two catheters pass through the tube wall, and are connected with separate bottles, both of which can be exhausted by one rubber-air-pump. Apart from this apparatus is a metal lever, 24 cms. long, with a laterally flattened, curved end. After passage of the compound tube in the ordinary way, each catheter is rotated longitudinally, the proximal end of the covering tube pointing outward and backward, as revealed by the distal extremity; the angle subtended posteriorly by the catheters becoming equal to about 120° to 140°. Pressure now exerted by the lever *per vaginam aut rectum* raises the floor of the bladder in the middle line, and produces two miniature drainage areas, with a watershed between, so that the water supply from the ureter of the one side forms a rivulet quite apart from that of the other.

The descent of the water is facilitated by gentle aspiration. Each exhaust bottle now receives the unmixed excretion of the corresponding kidney, and the condition of these organs can be diagnosed with confidence.

3. PEPTONES AND ALBUMOSES IN THE URINE.

BANG (*Deutsche med. Wchnschr.*, Leipzig, 1898, No. 2) points out that the method of HOFMEISER and SALKOWSKI for detection of the presence of albumoses in the urine is open to fallacy from the very similar reaction given by urobilin, and proposes the following clinical method, which has the merit of considerable simplicity. To 10 c.c. urine 8 grms. ammonium sulphate are added, dissolved with heat if necessary, and the mixture briefly brought to the boil. It is then centrifuged for a half to one minute, the precipitate separated from the supernatant liquid, and rubbed up with 97 per cent. alcohol. The alcohol removes any urobilin, while, should the remainder, dissolved in water, boiled, and filtered, answer to the biuret test, albumoses or peptones are present. A remote cause for further fallacy is given by hæmatoporphyrin, but the pigment may be removed by the addition of chloride of barium and filtering. SALKOWSKI (*Berl. klin. Wchnschr.*, 1897, No. 17) and HARTOGH (quoted *Centralbl. f. innere Med.*, Leipzig, 14th May 1898, from an *Inaug. Diss.*, Freiburg, 1897), after extensive investigations, show that urobilin is frequently mistaken for peptone and albumoses in the urine because of its reaction to the biuret test.

LENOBEL (*Wien. klin. Rundschau*, 1897, No. 27, quoted *loc. cit.*) points out an important point with regard to albuminous urines, which also contain proto-albumoses. Proto-albumoses isolated from the urine, has a very strong action in preventing the coagulation of albumine in the ordinary methods used in practice.

HAAK (quoted *Schmidt's Jahrb.*, Leipzig, 1898, Bd. lii.) employs the addition of an amount of absolute alcohol five to ten times the volume of the urine, and extraction of the precipitate, formed after twenty-four hours, with boiling water.

ROSIN (quoted *Centralbl. f. d. Grenzgebiete d. Med. u. Chir.*, May 1898) records the case of a woman of 36, with head and back ache, or debility. The urine gave a large deposit with HELLER's test, and contained casts and thickened epithelium. In spite of the absence of all the general signs of acute, chronic, interstitial, or parenchymatous nephritis, the case apparently was one of Bright's disease; after three weeks, when the patient had not been relieved from her symptoms by iodide of potassium and milk diet, it was found that the urine contained no albumin, Heller's test gave a dense, opaque, white ring, but this cleared up on heating, and reappeared on cooling, beginning first at 58° C. to precipitate, at 72° C. to disappear again. The patient died, and was found to have been suffering from sarcomatous growths in many of the ribs.

4. DIABETES.

STERN (*Med. Rec.*, N. Y., 21st May 1898) has devised a small, neat, and, from the description, a sufficiently accurate apparatus for clinical work, to facilitate Robert's fermentative estimation of dextrose in urine. Its essential feature consists of two glass tubes, one wide to contain 100 c.c., the other narrow for 50 c.c. of urine. The tubes are united together by a solid glass curved tube, and stand upright on a wooden pedestal. In the narrow tube 50 c.c. of urine are placed, and a urinometer is put in, the whole being covered with a cap. Into the broad tube 3 or 4 grs. of yeast and 100 c.c. of urine are introduced, and another urinometer employed, the stem passing through a metal adjustable cap. After twelve to fifteen hours the difference in the readings will indicate the loss of sugar, 1 equalling 0.2196 grm. dextrose per cent., or 1 gr. in a fluid ounce.

Several papers have been published in connection with the diagnosis of diabetes, by means of the appearance presented by the red blood corpuscles, after staining with various aniline dyes, such as methylene blue 1 per cent. for one or two minutes, Congo red, and Ehrlich-Biondi's fluid. Each of these differentiates between healthy and diabetic blood, by the colour or absence of colour produced (Bremer, *Centralbl. f. innere Med.*, Leipzig, 7th June 1897, and 2nd April 1898; Löwy, *Med. Wchnschr.*, Paris, 1897, p. 539; Marie and Goff, *Semaine med.*, Paris, 5th May 1897; Baduel and Castellani, *Settimana med. d. Sperimentale*, Firenze, 1898, No. 10).

5. ALBUMEN.

HUSCH (Wien. med. Wchnschr., 1897, No. 34) points out the possibility of there being a frequent fallacy attendant on HELLER's test. In concentrated urines, when the acid has been so added as to form a distinct line of conjunction with the urine, a cloud is formed from the urates present, which vanishes on heating, and which can be

hindered by previous dilution. The author found, in most urines that he tested, a similar cloud entirely independent of the concentration of the urine or the quantity of urates. Unlike the first (and unlike proto or hetero-albumoses, it may be added—A.L.G.), this cloud does not completely disappear on heating, while dilution of the urine increases rather than diminishes it. This he considers to be due to nucleo-albumins. Should a urine contain the ordinary coagulable proteids, excess of urates, and these nucleo-albumins, the coagulated and precipitated substances may be perceived to form three rings in place of the two hitherto accepted. The albuminous ring or cloud, forms the lowest of three in the test tube; over it comes a clear zone; then the opaque ring of urates, in which the author's power of vision enable him to detect a denser portion, also ring-like in form, which consists of a layer of coagulated nucleo-albumins.

Further, JOLLES (*Wien. med. Wochenschr.*, 1897, Bd. xlvii. S. 22) shows that in cases of pseudo-leukaemia, a milky precipitate falls on addition of acetic acid, which, after solution in carbonate of sodium, is not brought down by saturation with magnesium sulphate. This body he recognises as nucleo-histone.

7. URIC ACID.

RINGLES (*Wien. med. Bl.*, 1897, No. 21) describes a method of estimating uric acid by volumetric measuring of the gas evolved by the addition of dilute but still strong nitric acid to the urine. It would be superfluous to mention here the details of the separate factors necessary for calculating the proportion of uric acid; not only the pressure of the atmosphere and the temperature of the air have to be reckoned with, but the tension of the steam, given off by the urine when boiling, accounted for. A very simple method, as the author remarks, but bristling with rather too many aims for the practitioner unacquainted with anything beyond the rule of three.

TUNNICLIFFE and ROSENHEIM, in the *Brit. Med. Journ.*, London, for 4th February of this year, advise the use of piperidine as a reagent for the estimation of uric acid. This body forms soluble salts with the acid. To estimate the actual amount present, the uric acid in 100 c. c. is precipitated with ammonium chloride, the ammonium salt split up by hydrochloric acid; the uric acid thus obtained washed free from hydrochloric acid and tested with a solution of piperidine added from a burette; 0.425 grm. piperidine equals 0.84 uric acid.

7. RENAL PERMEABILITY

ACHARD and CANTAGNI, (*Gaz. hebdom. de med.* Paris, 1897, tome xlv. p. 37) inject hypodermically 0.05 grm. of 5 per cent. solution of methylene blue, after the bladder has been emptied, and get the patient to pass urine a half, one, two, three hours and so on. The first appearance of a green tinge, or abstraction of the blue after shaking with chloroform, normally begins in half-an-hour, the amount in the urine increases for three or four hours, and does not entirely disappear until from thirty-five to fifty hours have elapsed. In disease of the kidneys, the reaction appears much earlier. The conditions leading more especially to this earlier elimination are found in functional kidney diseases, and in diffuse, acute, or chronic affections of the renal interstitial tissue. The authors regard the method as one capable of affording much infor-

mation in cases where there is albumin in the urine but no casts, or *vice versa*. BARD (*ibid.*, 1897, tome xlv. p. 42) fully corroborates the conclusions of these authors, who again return to the question, as especially concerned with cases of congestion brought on by nephritis (*ibid.*, 1898, No. 16). The test here again fulfilled anticipations, and, moreover, was found to constitute a valuable clinical method of testing the condition of the renal tubules, quite independently of changes in the diet or in the environment.

—:O:—

THE BEST METHODS OF SURGICAL STERILIZATION.*

By EDWARD BOECKMANN, M.D.

Consulting Surgeon, Chicago, Great Western Railway,
St. Paul, Minnesota.

WHILE surgical sterilization is open to improvement and does steadily improve, it is to be regretted that the best methods of attaining this desirable end are matters of dispute among the three principal schools. Thus while (1) the English school teaches chemical sterilization which means the destruction of non-spore bearing pyogenic bacteria only, the (2) German school advocates the extermination of all surgical bacteria, spore-bearing or not, pyogenic or not, by the aid of heat, and (3) the French school aims at both surgical and bacteriological sterility.

If the Englishman is right, his method is certainly the quickest and the simplest, as all that he requires is a cold solution of carbolic acid; but the German, if he is right, has the sympathy of the majority of Surgeons and needs sterilizers for boiling water or for ordinary steam which the Englishman has no use for. If, however, the Frenchman, with his expensive and cumbersome high-pressure sterilizers be the only one who is really right, surgical sterilization will never become popular outside of hospitals.

In surgical work we aim not only at sterility but also at atoxicity or cleanliness, and while it is of some importance to remove chemic impurities of all kinds by washing, scrubbing, scraping and shaving and to secure at least three-fourths sterility by mechanical sterilization, we must also insist upon complete destruction of our real enemies; as the surgical failures through imperfect sterilization are invariably due to sepsis *i.e.* to the action of pyogenic, not spore-bearing bacteria. And though we have once or twice heard of a patient dying from anthrax or tetanus, where do we ever hear that a patient succumbed to tubercular infection or vibrio septicæ through faulty sterilization?

The real question is:—Will killing the less resistant pyogenic bacteria suffice (English) or is it necessary to destroy and remove all known surgical bacteria and their spores (German) or must bacteriologic sterility (French) be obtained?

CHEMIC STERILIZATION.

Has for its stronghold not surgical sterilization, but antiseptic surgery, which forgiving many minor surgical sins and glossing over gross mistakes cripples, without destroying bacteria, thus giving nature time until the chemicals are disposed of in the organism, to organize the defence and prepare for the offensive.

* Read at the Fourth Annual Meeting of the American Academy of Railway Surgeons at Chicago: Ill. and specially reported for the *Indian Medical Record*.

Looked at as antiseptics, chemicals are of great value, but from a germicidal point of view their action in surgical sterilization is very limited, and though nobody denies that certain chemicals are germicidal in proper concentration; still they have no immediate action and the bacteriologist has not as yet been able to definitely determine the germicidal action of any given solution on pure cultures of surgical bacteria, as it is impossible in most instances to eliminate the chemical before the test thread or whatever is employed is transferred to the culture medium.

Under the best of circumstances chemic sterilization is not only very slow but it is also injurious to our surgical instruments and materials and unpleasant to the surgeon, as well as even dangerous to the patient.

THERMIC STERILIZATION.

Is more complicated and more expensive than chemic, as fire and apparatus are necessary; but what little we lose in money is more than gained in time, since thermic sterilization acts in as many minutes as the chemic does in days, and those who prefer antiseptics to asepsis cannot possibly object to asepsis itself which they can easily and readily supplement with antiseptics whenever they may choose to.

Boiling water is the first, last and best sterilizing agent in surgery, and steam ranks next, while hot air is effective only when maintained for hours together in the neighbourhood of 300°F; but the mixed method of mechanical and thermic sterilization combined with judicious antiseptics best recommends itself to all surgeons.

SKIN STERILIZATION.

Cannot be effected through the entire thickness of the derma, whose surface must be so well prepared by shaving, washing, scrubbing, scraping and brushing, that scraping will not develop any cultures.

In cleansing the skin mechanically it is but common sense to use the warmest and cleanest water possible, and to shave off any hair that may come within the field of operation.

After the first series of shaving, scraping and thoroughly washing with soap and hot water, is over, (1) the English saturate the surface with turpentine and again scrub with soap, and a mixture of 1 in 20 carbolic and 1 in 500 sublimate solutions; but the Germans dry the part with sterile gauze after which they saturate it with 80 per cent. alcohol and brush it over with 1 in 2000 sublimate solution; the French use ether in place of alcohol.

The turpentine, alcohol or ether is employed to further mechanical disinfection by dissolving impurities of various kinds and helping to remove grease and fatty matters from the skin; but turpentine is not only the cheapest and most

convenient of the three, but it is also the best as in return for removing its impurities, it varnishes the skin and covers up the bacteria more perfectly than does lanolin, though if lysol is going to be the antiseptic employed it must be used before the impregnation with turpentine, as it takes no effect when the skin is varnished.

The operator cannot be too careful of the absolute cleanliness and almost perfect asepsis of his hands, and the knife ought to be cleansed anew (or a fresh knife used) after the skin has been cut through, while the best method of surgically sterilizing the skin is:—(1) shave the operation field, (2) with a stiff sterile brush and plenty of hot sterile running water scrub the skin for several minutes, (3) cleanse the nails, (4) repeat the scrubbing using lysol, sublimate, carbolic acid, permanganate of potash or other antiseptic solution, (5) dry the skin with sterile gauze, (6) impregnate it with turpentine and (7) remove the oil with sterile warm water or a mild antiseptic solution. It ought to take 10 minutes to do all this.

STERILIZATION OF INSTRUMENTS.

While the English School merely immerses the instruments for two or three hours (before the operation) in a 1 in 20 carbolic acid solution, the German boils them for 5 minutes in a one per cent. sodium carbonate solution, and the French includes prolonged boiling in 0.5 per cent. potassium carbonate solution, dry heat and a variety of other methods.

The French are extravagant in their sterilization of surgical instruments and while they speak of surgical they really aim at bacteriologic sterilization. Some boil in the presence of potassium carbonate while others use boiling oil, vaselin, glycerine and such like. But these methods are superfluous and must give way to the German method (of boiling the instruments for a few minutes in weak alkali solution) which is simple, convenient, absolutely reliable, and can be done during the time the skin is being prepared for operation.

Many find that boiling water makes the instruments dull and rusty. This is true; but if rain or distilled water to which a few drops of Liquor Potassæ have been added, be employed, and the instruments not immersed till the water is boiling nor kept soaking for more than 2 to 5 minutes, they come out bright, clean, sharp and aseptic, and will not rust readily. Rusting can further be guarded against by wrapping the cutting instruments up in dry cotton.

Whenever thermic sterilization can be used, it is imperative to choose it in preference to all other methods on account of its mathematical accuracy; though where it is not practicable chemicals may be substituted for it, as they are better than nothing.

In hunting for a safe quick chemic method, the very much over-rated agent formalin was brought to the front

too conspicuously ; but time will show that though it may stick a long while to articles exposed to its action and thus give an exalted idea of its sterilizing superiority, formalin has no real advantage over carbolic acid or other chemicals.

DRESSINGS.

The Englishman sterilizes his dressings by the aid of carbolic acid, corrosive sublimate or other antiseptic solution, with subsequent wringing out in weaker solutions or sterile water before application ; but as the oozing from the wound precipitates the chemicals the dry dressings sold by the manufacturers in containers of guaranteed chemical sterility are a great humbug, in spite of the well-meant efforts of the manufacturing house to make them reliable : more especially as dressings, sterilized by chemicals, are reliable only when they are conveyed directly from the antiseptic fluid to the wound.

The German places his dressings, already thoroughly cleansed by washing and drying, in a steam sterilizer so built that the steam extending from above and escaping below expels all air, and at the same time permeates every particle of the articles placed in it. The whole process takes 30 minutes and the dressings are conveyed directly from the sterilizer to the wound.

To keep sterilized dressings ready for use all the time, BLOCH's method is the most practical and the simplest. The gauze wrapped up in a double layer of filtering paper (readily penetrable by steam, which ordinary paper is not) is tied, marked and put into the sterilizer where it is thoroughly steamed and afterwards perfectly dried. And so long as the covering of filtering paper remains dry the contents of such packages will remain sterile. Any one can unroll the outer layer, and the surgeon picks out the inner which contains the gauze, ready for use.

The French system of Autoclave (i.e., high-pressure steam) sterilization would be the acme of perfection, were it not that besides being expensive and cumbersome the autoclaves are stationary apparatus that answer admirably for large hospital practice ; but do not give the dry dressings that can be obtained in sterilisers made after the German principle.

SUTURES AND LIGATURES.

Are of various materials, but as examples of inabsorbable and absorbable suturing and ligating materials we shall take silk and catgut.

Silk being capable of remaining for almost any length time in strong antiseptic solutions of repeated boilings without detriment, the English school allows it to soak for a few days in 1 in 20 carbolic acid solution, while the German sterilizes it by steam or by a boiling ; but the Frenchman who is just as extravagant in his treatment of silk as in his sterilization of all other articles, boils his silk first in filtered water, then antiseptic solutions and finally steams it in the autoclave.

Catgut can neither be boiled nor steamed though it can be submitted to gradually raised dry heat of 230°F.

without deterioration and can be sterilized by a variety of chemicals ; but it requires days and weeks for the antiseptic to accomplish the same purpose that heat can produce in a few hours.

Thus while the Englishman soaks his catgut for at least a week in carbolic acid solution, the German sterilizes it with various chemicals and the Frenchman by exposing it to dry heat for several hours.

As aseptic catgut sterilized by dry heat takes a clean Surgeon to handle it successfully since it is a good culture medium for bacteria, the problem of the future is to impregnate catgut with a non-irritating antiseptic which will remain with it until the last fibre is absorbed : When this is attained, and not till then, can we speak of ideal catgut.

DISCUSSION.

DR. JOHN E. OWENS, who mentioned some post-operative fatalities which were directly traceable to infection from the material employed for suturing and ligating, cautioned against the use of commercial catgut and strongly advised the surgeon *himself* to see to the proper sterilization of ligatures and sutures that he uses.

DR. ARTHUR D. BRYAN believed that catgut could be thoroughly sterilized by a number of different methods which did not however assure primary wound-healing if the suture employed was catgut, which does sometimes contain irritating and toxic substances which may produce suppuration or which may contain some pathogenic germ capable of producing conditions resulting in suppurative changes : This, because no surgical operation is absolutely aseptic. He recounted his experiences with the various methods chemical, &c., of sterilizing catgut sutures, and said, that if we accept the fact that no wound is sterile, we would find that the factors which produce suppuration are many times chemical, not necessarily the germs themselves, because we always have them present, but other added factors among which are tension, tension produces necrosis, unremoved blood clots and dead or mutilated tissue, infection from the intestinal tract, a syphilitic or scrofulous diathesis, low health, diabetic symptoms &c. He pointed out that a clean incision unites much more readily than one in which we have tearing and gross tissue and concluded a lengthy though very interesting speech by pertinently remarking. "There are many other factors that are as important almost as the reduction of infection to a minimum, which is certainly all we can ever accomplish in the field of operation."

DR. R. HARVEY REED, then told the meeting, that he had noticed that in infected wounds the infection only extends to the integument and down to the deep fascia. He was in favor of pyoktanin catgut because pyoktanin stained the catgut blue throughout when properly saturated rendering it easy to tell, before using the

suture, whether the suture was fully sterilized or not. He objected to chromicized catgut because it was stiff like wire and was less easily sterilized and absorbed with more difficulty than the pyoktanin catgut which was soft, pliable and quickly absorbed when employed as buried sutures. He did not think infection, when it did occur, was due to pressure or to infection from the suture employed, for if it were, it should also extend, which it does not, to the peritoneum which the suture often penetrates and includes in major operations, as in abdominal sections; and he found it was possible to have infection from outside, no matter how carefully applied or how aseptic the dressings. He tried to avoid this by using buried (*sterilised*) sutures of catgut, kangaroo tendon and silk-worm gut, but as in many instances where the sutures reached the surface, infection took place from without and worked down and inwards in spite of the sterilized materials, he now avoids stitch abscesses by employing silk for exposed and silk-worm gut for buried sutures, and dresses the wound with antiseptic dressings to prevent the entrance of germs from the surface following up the suture and producing an infective centre.

Dr. J. P. LORD thought that better results would be obtained if instead of putting the sutures so far apart as they do, surgeons took greater care to make the tension uniform and not to expect too much of any one suture.

Dr. L. E. LEMEN remarked that post-operative suppuration was chiefly, if not wholly, due to pressure necrosis induced by passing the stitches through the entire abdominal wall and including so much tissue in the stitch.

Dr. W. J. GALBRAITH believed more serious results were produced by the improper insertion of sutures than by the surgeon's knife, as *all* wounds, no matter how carefully the asepsis and antisepsis are carried out, contain more or less infective material and if a suture were applied too tightly it caused strangulation which promoted inflammation and tissue destruction, thus furnishing a suitable culture field for greater development of existing bacteria. Although he did not believe it possible to use any preparation of suture material without evil results, he had secured better results from catgut than from anything else.

Dr. W. W. GRANT stated his greatest dependence on chromicized catgut (as prepared by Mr. LISTER) which he imported from London and placed in 5 per cent. carbolic acid solution, shortly before using it.

Dr. N. SEEN stated that since their adoption of the modification of HOFMEISTER's formalin preparation of catgut (for a detailed account of the method see *Indian Medical Record* Vol. XIV, page 204 under ideal catgut sterilisation). Several of the hospitals in the United States had done away with the evil results and had noticed no stitch abscesses.

FIFTEEN YEARS' OBSTETRIC PRACTICE IN CALCUTTA.

By JAMES R. WALLACE, M.D., F.R.C.S.I.
*Fellow of the Obstetrical Society of London,
formerly Resident Surgeon to the Eden Hospital
for Women and Children, Calcutta, &c., &c.*
(Continued from Vol. XIII., page 231).

THIRD FIVE YEARS' SERIES.

IN the annexed tabulated statement I record the *third five years' series* of obstetric cases which embraces a total of 350. In the *first five years' series* I recorded 199 cases or a percentage of 8.31 labors attended per mensem. In the *second five years' series* I recorded 304 cases giving a percentage of 5.6 labors per mensem. In this *third series* I record 350 cases or a percentage of 5.6 labors per mensem. Of these 134 were natural labors, and in every instance I was pre-engaged to attend these cases, and in each case labor terminated favorably to both mother and child.

GENERAL ANALYSIS of the 350 cases shows that 197 were primiparæ, the oldest of whom was 37 and the youngest 15 years of age. Of primiparæ, 106 required the use of forceps, of multiparæ, 68 were so treated, 49 in their second labor, 9 in their third labor, 9 in their fourth labor, 3 in their fifth labor, 1 in the seventh labor, and 1 in the eleventh labor. There were 6 *twin* labors, 1 in a primiparæ, 1 in a second labor, 1 in a third labor and 3 in fourth labors.

PRESENTATIONS. The table shows the following:—Head 282, Breech 34, Arm 18, Face 12, Foot 11. Among these were 6 twin births, of which 7 were head and 5 breech. The Funis presented with the head in 2 cases and with the foot in 1. Of the 350 cases only 134 ought rightly to be classed as Natural Labors, i.e., the head presenting and labor being completed within twenty-four hours without difficulty or complication of any kind. At least 60 per cent. of the Head Presentations were of the Left Occipito Anterior variety.

INSTRUMENTAL INTERFERENCE:—Forceps 158, Podalic Version 18, Cephalic Version 1, Incision of Os prior to effecting delivery 10, Craniotomy 1, Blunt Hook 1.

ANALYSIS OF FORCEPS CASES:—Forceps were used in 158 cases for the following reasons:—For Tardious Labor (due to inequality of either the head of the child as compared with the vaginal passage, or *vice versa*) in 58 cases, Rigid Os in 34 cases, Uterine Inertia in 19 cases, Puerperal Eclampsia in 2 cases, for Obstructed Face to Pubis in 12 cases, for Obstructed after-coming Head in Breech Presentation in 7 cases, Narrow Pelvis in 11 cases, Hydrocephalus in 1 case, Puerperal Mania in 1 case, for Exhaustion or other unfavorable symptom, such as fever, sepsis etc. threatening danger to both mother and child 14 cases.

DR. WALLACE'S THIRD FIVE YEARS' SERIES.—Tabulated Statement of Midwifery Practice in Calcutta for Fifteen Years.

NOTE.—E. stands for European, A. I. for Anglo-Indian, A. for Armenian, J. for Jew, H. for Hindu, M. for Mohammedan, and B. for Burman.

*1 was taken ill 18th August and was absent from work up to 17th October.

A MIRROR OF PRACTICE.

A CASE OF DIPHTHERIA SUCCESSFULLY TREATED BY THE TOPICAL USE OF CITRON JUICE.

By ASSISTANT SURGEON E. S. PUSKONG,
Station Hospital, Lucknow.

THE patient was a Bengalee girl, aged 12. The history given was a feeling of indispotion for a couple of days previous, extremely dull and apathetic, with discomfort about the left side of the throat, the girl imagining that this was due to a prick from a fish bone, an accident which was supposed to have happened while eating some fish a few days before—she seemed extremely hungry and stated that she would be well if she could only swallow.

Clinical Features.—At the first glance it looked like a case of mumps, so intense was the cellular infiltration of the neck on both sides, with collateral swelling of the cheeks and floor of the mouth. I found the tonsils enlarged and congested, the posterior pharynx being completely hidden from view, the soft palate was also much congested and tumefied.

The diphtheritic membrane was seen to stretch from the soft palate over the left tonsil, but its posterior extension could not be gauged owing to the inability to see beyond the presenting surfaces of the tonsils. Breathing was natural—Temperature was 102° F. Pulse even at this early stage (3rd morning) was weak and fluttering. Very little difference took place for the first three days under treatment, on the fourth day however the throat was more open to view, the tonsils having become somewhat smaller, and I managed while swabbing the throat to remove a great portion of the membrane, without violent effort. Citron Juice was now used to swab the throat with.

On the 5th day, I found that the right tonsil which up to this date was clear, with the exception of a very small speck on its anterior surface, was now covered with the diphtheritic membrane. Temperature still ranged between 102° & 108° F. with a little muttering delirium during the night. Treatment was persevered in, with the result that on the sixth morning nearly the whole of the throat was clear. I also noticed a peculiar nasal twang about the voice, and when swabbing the throat a slight muco-purulent discharge exuded from the left nostril. This led me to suspect invasion of the posterior nares, there was slight embarrassment in the breathing which caused great anxiety, I however still employed the same line of treatment with the pleasing result that the next day while the girl was blowing her nose, which she had been advised to do several times a day, numerous large strips of membrane came away, all nasal symptoms for a time subsiding with the exception of a slight serous discharge.

On the 9th day, the posterior pharynx could be clearly seen, though the throat was still studded with small islands of membrane, especially on either side of the uvula and behind the anterior pillars of the fauces. Temperature still ranged between 102° & 108° F.

The temperature continued high owing to the forma-

tion of a left parotid abscess, which I afterwards opened and drained, when it gradually fell to normal.

On the 12th day, there was a muco-purulent discharge from the right nostril, this time with a feeling of pain and discomfort about the region of the nasal bones, and slight difficulty in breathing, but in a couple of days, the muco-purulent discharge gave place to a simple serous one. Temperature still between 101° & 108° F.

On the 17th day, I opened and drained the parotid abscess. The child was now convalescent, having so far escaped with but a slight post-diphtheritic paralysis of the soft palate.

Treatment :—

R	Tr. Feri. Perchl.	m℥.
	Quinin Sulph.	gr. iv.
	Potass Chlor.	grs. viii
	Tr. Aconiti	m℥i.
	Aque.	ad ℥i.

T. D. Until complete disappearance of the membrane.

R	Acidi Carbolic	℥i.
	Camphoræ	grs. 20
	Ol. Oliv.	℥i.

To be applied locally every 2 hours.

Inhalation every hour during the day till the fourth day when the throat was found sufficiently open to use this Gargle.

R	Acidi Carbolic	℥i.
	Ol. Terebinth	℥i.
	Aqua. Bull.	oj.
R	Gly. Acid. Carbolic	℥iv.
	Gly. Acid. Borici	℥vi.
	Aque.	ad ℥i.

Sig. A small quantity to be used as a gargle frequently during the day with equal quantities of warm water, as warm as could be borne. Citron juice was ordered to be dropped into the nose every 2 hours, and the following nasal injection was used several times a day.

R	Acid. Borici	℥iv.
	Boracis	℥vi.
	Aque.	ad oi.

Sig. Use with equal quantities of warm water.

Gentle stimulation was adopted from the onset, 5ss. of brandy being given every 2 hours, this being replaced by Coca-wine, half a wineglassful three times a day when convalescence was established.

Remarks.—Though the diphtheritic virus is superficial and in the membrane itself, and does not extend into the subjacent mucosa, yet I cannot help but applaud the now nearly lost sight of, yet once highly praised treatment by citron juice.

I cannot help but praise the juice, for though the membrane for the first two days had stopped all apparent growth under the application of Carbolic Acid and Camphor, yet there was no sign of separation although the swab was applied with some force on these occasions, until the third day when I resolved to try citron juice in combination, with the result that on the fourth day I was able with ease to remove a great portion of it.

FATAL DIARRHŒA DUE TO ASCARIS.

By SURGEON-MAJOR R. E. WEAFFER, I. M. S.

Dakra Doon.

The patient, a child ten years of age, was sent to the local Municipal hospital for treatment of diarrhœa. The patient looked very ill. The eyes were sunken, the pulse small and thready, the face shrunken and anxious. On inquiry I learned that she had passed that morning four or five watery motions, and along with her motions, one big round worm. Had it not been for the presence of this worm, I would have treated it as a case of diarrhœa. But this single worm pointed to no other conclusion than that this diarrhœa was set up by worms. Acting on this diagnosis, I gave her one two-grain powder of santonine, and in addition, a stimulant mixture to brace her up. Next morning she passed two worms. The medicine was continued, and she passed the following day nine worms, the day after nine worms, the next day 28 worms, then 31, till in 8 days she passed 111 worms, the diarrhœa was kept under control by suitable astringents, but she gradually got worse, and died a week later, considering the number of worms passed, merely 111, it is no wonder that this set up an irritation which brought on the fatal diarrhœa. Whether the diarrhœa was due to quite a distinct cause and that the worms did not contribute to the affection are questions which I leave to the decision of the reader, (from Dr. MITRA's paper in the *Boston Medical and Surgical Journal*, December 5, 1896.) BRAITHWAITE'S Retrospect of medicine. Vol. CXIII, January to June 1896, p. 88.

Remarks.—Worms are an occasional cause of diarrhœa in children. One of the most constant signs is the passage of a quantity of jelly-like mucus with the motions, while at the same time the bowels are disordered and the general health is unsatisfactory. Such are the chief symptoms, which are however, by no means positively distinctive of worms. A leucorrhœal discharge from the genitals may also occur in children, as a result of the irritation caused by worms, especially by thread worms. The malady mostly occurs in greatly enfeebled lymphatic and scrofulous girls from six to fifteen years of age, and may be more or less profuse, and of a yellowish-white colour, adhesive, sometimes glueing the surfaces of the vulva together. The child does not experience any pain or inconvenience, and the complaint, in simple cases, is unattended with any external signs of injury or inflammation.

COBRA-BITE TREATED WITH TOBACCO ASH : RECOVERY.

By TRICAMALL MAYANLALL, C.M.S.

In Medical charge, Bilara Dispensary, Marwar.

WHILE attending to the roof of her house on the morning of the 7th July 1898, TIVER, a hindu female, aged 23 years, was bitten on her right wrist by a cobra. The wounds bled pretty freely but as the woman was in a semi-conscious condition when brought to the dispensary at about noon, her face was freely drenched with an infusion of neem leave for nearly 15 minutes. This rallied her somewhat and at 1-P.M., she was sufficiently conscious to complain of feeling drowsy and asked us to not disturb her.

Quarter, of an hour later she was made to swallow 60 grains of tobacco ash—the residue obtained by smoking tobacco mixed with treacle and certain aromatics and consumed in a hooka or Indian pipe—and this was repeated thrice, at half-hour intervals ; but at 2-10 P.M., she vomited a quantity of clear watery matter and an hour later sat up saying she felt less drowsy, though there was a good deal of nausea and headache.

She was given some neem leaves to chew and the tobacco ash reduced to 20 grain doses at 45 minutes intervals till 7-P.M., when the giddiness left her and she was given some milk to drink.

At 10-P.M., she was given her last dose of 20 grains of tobacco ash—making in all 360 grains—and kept on milk diet for the remainder of the night during which she was not allowed to close her eyes. No further treatment was necessary and the woman left the dispensary, (well) on the morning of the 8th July.

I have successfully used tobacco ash in five other cases and would like to learn whether any of my confrères has had a similar experience; but a curious feature in this case was, that when the woman chewed the neem leaves at 2-P.M., she said they tasted sweet, though at 4-P.M. she found they had their natural bitterish taste.

CARBUNCLE ASSOCIATED WITH DIABETES.

By ANTHONY FR. FERNANDES, C.M.S.

Daman, Portuguese India.

ON the morning of the 15th July ultimo, I was called to see a Mahomedan gentleman. I found him in fever, 102-2 accompanied with ague, headache etc. Thinking this a mere febrile attack I treated him accordingly with satisfactory results. On my third visit the patient drew my attention to a painful spot in the dorsal region, and at the same time complained of frequent micturition. I found the spot complained about of a dull red colour, intensely painful and tender to the touch, about an inch to the right of the inferior angle of the left scapula. I ordered extract Belladonna mixed with glycerine to be smeared over the part and a linseed poultice applied over it and the morning urine to be sent to me for examination. The result of which was, Sp. gravity 1085, reaction acid, and distinct traces of sugar.

The tender spot in a few days became very inflamed and the pain unbearable, but the patient would not allow any incisions to be made. Ultimately suppuration took place, the pus being discharged from several mouths. Carbolic acid, 6 m. was now injected, iodoform dusted over the part and a charcoal poultice applied. This was continued until the discharge became nominal in quantity. The mouths all closed with the exception of one, which healed in a few day's time—micturition was now almost normal and no sugar was to be found in the urine.

Indian Medical Record.

16th September 1896.

PLAGUE IN INDIA. THE PLAGUE CASES IN CALCUTTA IN 1896.

PROFESSOR W. J. SIMPSON, M.D., Late Health Officer of Calcutta, in his address on "Plague in India," delivered before the British Medical Association at Edinburgh, reiterates his opinion that a number of cases of true plague occurred in Calcutta in 1896, as follows.

"That a disease, such as plague, may exist in a mild form for a long time before it manifests itself, either in its more virulent type, or in a local outbreak of considerable dimensions, may be gathered from the occurrences in Calcutta. The facts briefly stated are that the Shropshire Regiment which distinguished itself in Hong Kong, in cleansing plague-infected houses, lost three of its number in that colony from the disease, while double that number were attacked. From that time the regiment at intervals suffered in small groups from fever accompanied by glandular enlargements. This illness they brought with them to Calcutta, in January, 1896, and then other drafts of soldiers, who had never been to Hong-Kong, but who were brought in intimate association with their affected comrades, were attacked with a similar malady. At first the disease was diagnosed * * * as malarial fever with bubo, and ultimately the cause was registered as unknown. Some medical officers considered it to be a new disease; one of the medical officers was attacked in June of 1896, and the glands of the groin, axilla and neck were affected. In October, 1896, besides an imported case of illness from Bombay with fever and glandular enlargements, a number of cases occurred in Calcutta, but with symptoms of a more acute form, and of less duration than the cases in the Shropshire Regiment, which was still continuing to get fresh cases. There was fever, white-coated tongue with red tip and edges, congested eyes, dull intellect and glandular enlargements, mostly in the groin; children and young adults were chiefly affected. An adult who was affected and died, had all the typical symptoms of plague. From experience gained later in Bombay and Poona, I have not the slightest doubt that two other suspected cases which proved fatal, were cases of plague, and that the other cases of fever with glandular enlargements were benign plague, more severe in its character than some seen by me in Bombay and Poona. A peculiarity of these mild cases was that in some, a bacillus similar to the bacillus of plague was found in the blood. It could not be cultivated, however, unless, as it seemed to me, large quantities of blood or serum was drawn. In one portion of the town, somewhat later, there was a glandular and very fatal illness among rats whose organs were filled with diplo-bacilli, similar to the plague bacilli. Sick rats left their holes and slowly hobbled about or reared, apparently in a dazed condition. As many as 100 affected rats were counted in a small grain depot in one day. The houses were treated as plague infected, a campaign was waged

against the rats, and evidently with success, for the epidemic among the rats ceased. It is necessary to state here that my views regarding the nature of this glandular sickness among the inhabitants was not held by a higher authority, and that isolation of such cases was considered unnecessary. On the other hand, my further experience convinces me that the medical men who agreed with my views were right in their diagnosis, while some of the microscopical specimens sent to KITASATO elicited the opinion they were probably plague bacilli. It is a question, therefore, that ought to be very carefully inquired into. In connection with the occurrence of such cases in Calcutta, and their nature, the Report, dated 16th July 1897, of Dr. M. J. ROSENAU, the Californian Quarantine Medical Officer to the supervising Surgeon-General of the United States Marine Hospital Service, which I came across the other day, is interesting. It is as follows:—

"National Quarantine Station, Angel Island, California, 16th July, 1897.

"Sir,—I have the honour to report the British ship Annie Maud, one hundred and forty-three days from Calcutta, was placed in quarantine to-day for disinfection. A short while after leaving Calcutta one of the crew was taken ill with swellings in the axilla, groin and elbow, and died. Two more of the crew suffered with buboes, from which they recovered.

"Very respectfully, M. J. ROSENAU, Passed Assistant Surgeon, U.S., M. H. S."

One other point is deserving of notice, viz., that in 1897 there was an epizootic outbreak in Calcutta among cattle in the same locality in which the rats had died some months before, and though it was called rinderpest at the time the symptoms differed somewhat from the ordinary cases under that name, and *post-mortem* examination showed a very congested and enlarged condition of the mesenteric glands."

It is very improbable that this *quæstio venata* will ever be definitely settled to the satisfaction of all concerned.

PLAGUE RESEARCH AND ADMINISTRATION.

Professor SIMPSON's remarks on these subjects are very apt and appropriate. They have a special value coming from one who is intimately acquainted with the country and the way its Medical Services are organised.

The facts stated are merely trite commonplaces in India, but we fancy they must have had the ring of startling novelties in Edinburgh.

"Most of our knowledge concerning plague is in a fluid condition, principally because, it is a new disease to the present generation of medical men, and because the opportunities afforded for its study in India have not been taken sufficient advantage of. In fact, they are great opportunities lost. Good work has undoubtedly been achieved by the different Foreign Commissions sent out by the several European Governments, and by the Scientific Committee appointed by the Government of Bombay in corroborating and adding to the researches of KITASATO on the bacillus, but the essentially English method introduced by SIMON and his contemporaries and which is continued with such excellent results by the Local Government Board in England has not been applied—I refer to the regular and systematic investigation of plague by special and thoroughly trained medical

officers, case by case and out-break by out-break, including all the circumstances connected with each, and combining with this research laboratory work. This ought to be done, no matter what is the cost, for at the most it can only be insignificant to the losses which India is being now subjected to. It was reckoned that Bombay at the time of the height of the plague lost £100,000 a day. Over 100,000 persons have died of the plague in Western India. The other day I heard Lord REAY declare that plague is the most important problem that the Government of India has to deal with. There can be no doubt that this is so politically as well as socially, and I would plead for the inhabitants of India, and for the sake of those who have commercial and social interests with her, and for the sake of humanity, that every effort which science and money can afford should be made to learn more about this disease.

This is impossible under the present arrangements, owing to India possessing no trained sanitary service. This is a subject I dwelt on very fully in 1894 at the Indian Medical Congress, and there was a resolution of the Government of India that such a service was to come into existence in the year 1900. The plague has probably upset the arrangements intended to have been made before such a service can be established, the first arrangement being the education in sanitary science in medical schools of the members of the proposed service. Plague has emphasised the absolute necessity of this service and the utter helplessness of India to combat disease without such a trained service. I divide the medical part of a sanitary service into three branches—(1) the administrative, (2) the investigative, and (3) the scientific—which should be in close connection with one another, and in large towns should form parts of one large department. Broadly in England, the administrative is represented by the local health officers and their subordinates, the investigative by the medical inspectors of the Local Government Board, and the scientific by the laboratory researches made into the causes of disease in connection with special investigations of either the medical inspector or local health officer.

In the absence of a proper sanitary service in India, laymen had to direct the operations against plague in Western India, and in a number of instances soldiers had to be employed for house-to-house inspection. Apart from the fact that it is impossible to turn men suddenly into well-trained sanitary inspectors, there was in this arrangement always the risk, among a highly imaginative people, unaccustomed to see the military in their houses, of considerable alarm being created, which would be intensified by the wildest rumours; while it was certain to give a handle to the many political agitators, who were only too ready to seize every opportunity for brewing discontent and mischief. However suitable the system might be for a military station, it could not be adopted for Indian towns generally. The policy which has kept the military apart from the people, except in cases of riot and other exceptional instances, appears to be one on a very sound basis. Plague no doubt is an exceptional event, but it is too much connected with the domestic habits of the people to be dealt with except by agents to whom they are accustomed. To the members of the British Medical

Association, as well as to those accustomed to the methods adopted in England with regard to epidemics, the system of placing the control and direction of an infectious disease into the hands of laymen must seem extraordinary. The following extract taken from one of the despatches published in one of the blue books in 1897, will serve to illustrate the system. It is as follows:—In view of the rapidity with which plague was spreading in the Satara district, a committee under the presidency of the Hon. Mr. SPENCE, and comprising the following officers, Mr. LELY, I.C.S. Mr. R. A. LAMB, I.C.S. Mr. A. C. LEGAN, I.C.S., and Lieutenant-Colonel J. W. WRAY, all of whom have had wide experience of plague measures, was appointed to devise measures for the prevention of the spread of the disease." I am sure the exceptionally able and distinguished administrators on this Committee, and who belong to a Government which is splendidly organised in other respects, would be the first to acknowledge that an organization composed of laymen is not fit to deal with epidemic diseases. The system can only be excused under the exceptional circumstances of there being in the country no properly trained sanitary service whose duty would be to control epidemics. A native and European sanitary service is needed to protect the civil population against the invasion and ravages of disease, just as a European and native army is required to protect them from the invasion of foreign armies.

Later on in the epidemic, by the despatch of Army medical officers and Indian medical officers from other parts of India, and by the sending out of a large contingent of medical men from England by the India Office, a nucleus of an administrative department was formed. But with reference to the Army medical officers, and the Indian medical officers, it was only robbing Peter to pay Paul, for many districts requiring European medical officers were denied of them. As a matter of fact, without plague duties, the medical officers of the Indian Medical Service have for many years been overworked and are not sufficient in number for the ordinary duties which have been assigned them and have a well-founded grievance in their inability to obtain the leave and furlough due to them. If we now turn to the second part of a sanitary service, namely, the investigative branch, consisting of a body of highly trained men whose sole occupation is to search out the causes of an epidemic and inquire personally into the manner in which it spreads among the inhabitants, it is found that no such branch exists in India. From the foregoing it will be seen that two of the most important branches of a sanitary service in India have still to be formed.

As regards the scientific branch, the Government of India and the Government of the North-West Provinces have been fortunate in possessing for some years past the services of Surgeon-Lieutenant-Colonel D. D. CUNNINGHAM, and Mr. HANKIN. Two laboratories, however, in a vast country like India, do not meet its requirements. Moreover, for the past eighteen months Professor CUNNINGHAM's laboratory has been closed, owing to his retirement and there being evidently no one to take his place. When the plague broke out in Bombay the Government of India very wisely requisitioned the services of M. HAPPEL, who was on a visit to the country pushing forward his

anticholera inoculations. And in a short time M. HARRIS announced his brilliant discovery of a new method of combating plague. This discovery was not, I would point out, made suddenly after the Government of India requested him to go to Bombay and provided him with a laboratory, but it was the result of many years' work in the laboratory, beginning at least ten years previously from the time M. HARRIS directed his attention to anticholera inoculations. I mention this because there is a disposition in some quarters to consider laboratories expensive luxuries, unless some discovery of the first magnitude is speedily made.

The Government of India has always been imbued with the great importance of establishing laboratories in India, but the state of finances has invariably blocked the way. This difficulty, however, disappeared in a most charming and unexpected manner in 1897, when a number of the Princes in India expressed their desire to commemorate the sixtieth year of Her Gracious Majesty's reign by establishing a Health Institute for India, which should have M. HARRIS as its first director.

The spontaneity of the offer and the generosity with which it was made was enhanced by the peculiar appropriateness of this royal memorial to our beloved Empress Queen, whose reign has been so distinguished for the advances made in scientific and preventive medicine. The Princes were anxious that the site should be chosen and the foundation of the Health Institute laid on the day of the Jubilee. Owing to delays over which possibly the Government of India had not full control, in consequence of its plague and famine work, the auspicious day was allowed to pass, and no foundation stone was laid. Everyone acquainted with India will know the importance of an auspicious day. It is the symbol of success and good fortune.

Exciting events follow quickly on each other in India and crowd out the preceding. War in this case, with its distractions and expenses, burst out in the North-West Frontier, and the golden moment was lost for the establishment of a magnificent Health Institute, which, while serving as a noble monument of the loyalty and liberality of the Princes, would at the same time be for India a landmark in the Victorian Era. Let us hope, however, that the check, however regrettable, is only of a temporary nature, though it requires a sanguine mind to overlook the fact that delays mean new interests arising, a certain amount of chagrin, and the imperilling of a noble project.

A similar fate, owing to similar causes, appears to threaten the Pasteur Institute of India, for which Rs. 77,000 was collected over two years ago, and a site offered by the Punjab Government. A letter from the Committee of Management of the proposed Pasteur Institute was addressed, over eighteen months ago, to the Government of India, asking for their sanction to this site. At a recent meeting of the Committee the members had to adjourn because no reply had been received to their letter.

I have given these instances, not because I think the Government of India unfavourable to these proposals, but as illustrating the fact which is too familiar with

those interested in sanitary progress in India, that under present arrangements, even the most important sanitary matters cannot have the attention paid to them which is necessary, and that the only remedy is a properly constituted sanitary service, similar to that which I drafted in my address in 1894, and which was approved of then by the Government of India.

As regards plague in India, it appears to me that the disease has come to stay, at least for a considerable time and it is consequently important on this ground alone, quite apart from other reasons, that a trained sanitary service should be established, and while doing all that is known to check its ravages, it is also necessary to systematically investigate and study the disease from every point of view, which cannot be done without laboratories and a specially trained service."

—:O:—

THE SIXTEENTH MEETING OF THE COUNCIL OF THE INDIAN MEDICAL ASSOCIATION.

IN accordance with Notices issued by command of the President, the Sixteenth Meeting of the Council of the Indian Medical Association was held at its Office, 50, Park Street, Calcutta, on Tuesday the 23rd August, 1898 at 6 P.M.

Present.—Dr. LAL MADHAB MUKERJI, Rai Bahadur, (President, in the Chair). Drs. J. G. ANDERSON, H. W. JONES, K. G. SIKKAR, RAKHAL DAS GHOSH, and J. R. WALLACE.

Business.—(1). The Notice calling the meeting having been read, the Minutes of the last regular meeting of the Council were read and confirmed.

(2). The Secretary laid on the table letters on the subject of Medical Education and Medical Examinations in India from the Director-General, Indian Medical Service, the Director of Public Instruction, Bengal, the Director of Public Instruction, Bombay, the Director of Public Instruction, Madras, the Registrar of the Bombay University, the Secretary to the Government of the Punjab, and the Secretary to the Government of Madras. The letters placed on the table all gave evidence of sympathy and appreciation with the efforts of the Council except the letter from the Government of Madras, which indicates the irritable and hostile spirit of the Medical College Council of Madras in its treatment of the representation of the Indian Medical Association. In view of the fact pointed out in the letter of the Director of Public Instruction of Madras that "The First Examination in Arts is now the general education test for admission to the L. M. S. Examination," and in view of the statements made in Surgeon-Major-General C. SETHNA's communication to the Madras Government, that the improvements made in Madras are quite recent and are in accordance with many of the recommendations of the Council of the Association, the Council regards the Resolution of the Madras Medical College Council as not only wrong, but absolutely uncalled for. For the satisfaction of the local medical profession it is deemed proper to insert the correspondence of the Madras Government.

MEDICAL EDUCATION AND MEDICAL EXAMINATIONS IN INDIA.

G. O., No. 336, Educational, dated 7th June, 1898.

Read.—the following letter from J. B. WALLACE, Esq., M.D., F.R.C.S., Secretary, Indian Medical Association, to the Chief Secretary to the Government of Madras, dated Calcutta, 20th May 1898 :—

Here follows the letter of the Council as it appeared in the *Indian Medical Record*, of 1st June, 1898.

Order.—No. 338, Educational, dated 7th June, 1898.

The foregoing letter from the Indian Medical Association will be referred to the Director of Public Instruction and the Surgeon-General for any remarks they may see fit to offer.

(True-Extract) G. S. FORBES, *Secretary to Government.*
To the Director of Public Instruction and Surgeon-General.

READ—also the following papers :—

From Surgeon-Major-General C. SITHORPE, O.B., F.R.C.P.I., Surgeon-General with the Government of Madras, to the Secretary to Government, Educational Department, Ootacamund, dated 11th July 1898, No. 286-Tour.

With reference to G. O., No. 338, Educational, dated 7th June 1898, I have the honour to submit the following remarks.

2. Many of the remarks of the Indian Medical Association are based on its experience of the condition of Medical Education in Northern India, and do not apply to Madras.

3. It will be seen from the *revised* Madras University By-Laws 192 to 237 and from the schemes for the re-organization of the Medical College and schools *now before* the Government and partly disposed of in G. O., No. 654, Educational, dated 22nd October 1896, that all possible steps are being taken to improve the tone of medical education in this Presidency, and that the Government is doing its best to look after the interests of the public by upholding the standard of medical education. Such important reforms can only be introduced gradually if they are to be appreciated and accepted by the public.

4. Considering the varying standards of education in India, I feel some diffidence in giving an opinion as to whether it will be possible to carry out the reform suggested by the Association, *viz.*, uniform standards of preliminary examination, of education and of professional examination throughout the whole Indian Empire.

5. As regards the proposed formation of a Medical Council to exercise disciplinary powers similar to those of the General Medical Council of Great Britain, the idea is undoubtedly an excellent one, but it appears difficult to put it into practice. The Council in India would as a matter of necessity be composed exclusively of Government servants, as there are so few medical men outside the Government Service who would be worth being placed on it. Such a Council would not in my opinion be of much advantage. It will, I think, serve the purpose in view, if the universities are given disciplinary powers over their graduates.

6. The Association's remark that "unfortunately in

this country at the present day the tendency is to lower and not to elevate the standard of medical education" is hardly applicable to Madras. As shown in the preceding paragraphs, the tendency is otherwise in this Presidency. We have no private schools which grant their own diplomas. Such a system is certainly pernicious and ought not to be tolerated—in fact no schools should be allowed to spring up except under the supervision and approval of the Educational Department as advised by the Chief Administrative Medical Officer of the Government.

7. It is not a fact that in Madras the Matriculation opens the way for the L. M. and S. degree. Candidates for this degree are now required to have passed the First Arts Examination before entering on their medical studies.

8. I agree with the Association that there should be uniformity in the degrees granted by Indian Universities by adopting the same nomenclature. In Madras a Degree in Sanitary Science has also been instituted, which the Association does not apparently seem to be aware of.

9. As regards the Military Assistant Surgeon class, students for this grade in Madras are educated almost to the L. M. and S. standard. A few years ago a trial was made, with the sanction of the Government of India to stop eleemosynary education and to recruit the department from amongst private candidates possessing the L. M. and S. degree of an Indian University, but as the scheme did not succeed, a reversion had to be made to the old stipended pupilage system.

10. The Madras Hospital Assistants are not educated in the vernaculars. Sometime ago there was a Local Fund school in Nellore which trained some of its men in the vernaculars for local work, but the school has since been abolished and the requirements of the district board are now met by the Medical Department. The system in force in Madras practically meets all the recommendations of the Association in this respect.

11. With reference to the appointment of professors to teach special subjects, Government is aware that great care is exercised in selecting the *best men available* and that no nomination is made unless it is jointly recommended both by the Surgeon-General and the Director of Public Instruction.

From the Hon'ble Mr. D. DUNNAN, M.A., D.Sc., LL.D., Director of Public Instruction, To the Secretary to Government, Educational Department, dated Madras, 22nd July 1898, No. 7974.

With adavance to G. O., No. 338, Educational, dated 7th June 1898, referring, for my remarks, letter from the Indian Medical Association, Calcutta, on the subject of reform in medical education and medical examinations in India, I have the honour to subjoin the resolution of the Medical College Council on the above reference.

"The Council being of opinion that the Indian Medical Association is a body in no way representative of medical opinion in India or even in Calcutta, and in view of the fact that Dr. WALLACE's letter contains such glaring inaccuracies and misstatements (especially as regards the standards of professional education and examination in Madras), consider that no useful purpose would be subserved by detailed discussion of the points raised in Dr. WALLACE's letter."

2. In these remarks of the Council I fully concur.
ORDER—No. 498, Educational, dated 11th August 1898.
Recorded.

No. 498, Educational, dated 11th August 1898.
(True Extract)

H. TRENMENHERE, *Secretary to Government.*

To the Surgeon-General.

„ Director of Public Instruction.

Editor's Table.

GOVERNMENT OF MADRAS, EDUCATIONAL DEPARTMENT.

LETTER FROM H. TRENMENHERE, Esq., I.C.S.,

Secretary to the Government of Fort St. George.

To

THE SECRETARY OF THE INDIAN MEDICAL ASSOCIATION.
Sir,

I am directed to acknowledge the receipt of your letter, dated 20th May 1898, and to forward herewith a copy of G. O., No. 498, Educational, dated 11th August 1898, for your information.

OOTACAMUND,
11th August 1898.

I have &c., F. J. WILSON,
For Secretary to Government.

After full discussion of the above subject it was *Resolved*:—That the Council of the Indian Medical Association hereby expresses its disapproval of the action of the Madras Medical College Council, as being improper, prejudiced and misleading, and that such action is calculated to injure the cause of higher medical education and to further damage the reputation of the medical educational agencies employed by the State of India.

Resolved, that further reasonable time be allowed for replies from the various Governments and that in the event of failure to obtain satisfactory action from the authorities in India, the Secretary be empowered to move the India Office and the General Medical Council of Great Britain in this matter.

(3) MONOPOLY OF PRIVATE PRACTICE BY GOVERNMENT DOCTORS.

The Secretary placed the following letter having reference to the above subject, upon the table.

FROM THE SECRETARY TO GOVERNMENT, N.-W.P. & OUDH.

TO THE SECRETARY, INDIAN MEDICAL ASSOCIATION.

Dated Naini Tal, 13th August 1898

Sir,

I am directed to state that the Government of India has forwarded to this Government a copy of your communication dated the 21st May 1898, and of its enclosures, containing the suggestion that in large cities and hill stations Government Medical Officers should be prohibited from engaging in general and family practice as apart from purely consultative practice. The suggestion has arisen out of the correspondence on the petitions sent to the Government of these Provinces by certain private British Medical Practitioners in Mussoorie for the abolition of the post of Civil Surgeon at that station, or his being debarred from private practice. I am to inform you that the Government of India has duly considered the matter and finds no grounds for interfering with the orders of the Government of the North-Western Provinces and Oudh which were conveyed in the Secretary's

letters, Nos. 441-V-310B, and 169-V-310B, dated respectively the 8th July 1897 and 28th February 1898.

I have &c., W. H. N. IMPRY,

Secretary to Government, N.-W. P. and Oudh.

After due discussion of the above subject it was decided that the Secretary do now appeal to the Secretary of State for India, and that arrangements be made for questions to be asked in Parliament in relation thereto.

(4). THE IMPORTATION OF DOCTORS AND NURSES FROM ENGLAND FOR PLAGUE DUTY IN INDIA.

After due discussion of the above subject the following resolutions were proposed and carried unanimously:—

Resolved—That the Council of the Indian Medical Association have viewed with considerable anxiety and alarm the policy of the Bengal Government in importing from England, medical men and nurses for plague duty in this Presidency, when local talent of suitable quality was so largely available.

This policy has resulted in a decided hardship to medical men and nurses in this country, who are in every way qualified for such duties, and the Council feel that it has just ground to complain against the action of the Government. They further desire to point out that such a policy, while inflicting a grievous wrong on local talent, by placing an unmerited brand of inferiority upon medical men and women educated in this country, not only stamps the system of Government medical education in India with the stigma of incompetency, but renders still more tangible and real the disabilities under which the Domiciled European and Indian Communities labor under the present system of Government.

If the plea be raised by Government that it was necessary to import English medical and nursing labour because of its superiority to locally-trained labour, the Council feel that this plea only still more strongly emphasises the position which it maintains, that State medical education in India is an admitted failure and demands reform. The Council from a public stand-point desire most emphatically to state that the importation of British medical and nursing labour for Plague duties, was absolutely unnecessary; and the utilization of outside talent, in view of the fact, that the men and women so employed were without experience of tropical diseases, of the languages, customs and social and religious prejudices of the people of the country, was a serious mistake, involving, as it does, the unnecessary expenditure of large sums of money in the passage to and fro of the persons so engaged by the India Office, the payment of large salaries, such as in no case would be paid to locally-trained labour, and the continued expenditure of large sums on such imported agencies, whether employed or unemployed.

Resolved—That the above Resolution be forwarded to the Bengal Government, the Plague Commission, and the Government of India, with a covering letter.

(5) DEATH OF DR. K. N. BAHADHURJI, M.D. LONDON.

The Secretary reported the death of Dr. KAIKHUSBOO NUSHERWANJI BAHADHURJI, which took place on Monday the 18th August at Malabar Hill, Bombay, from typho-malarial fever after a short illness of ten days. Dr. BAHADHURJI was born on the 2nd November 1860 and so was only 38 years of age when he died. He was educated in Bombay

and in London and took the degrees of M.D. and B.S., of the London University. He served as Honorary Physician to the Jambetjee Hospital and Professor of Pharmacology in the Grant Medical College. He did much important public work for reforms in the medical services and in the local medical profession of India. He was President of the Bombay Medical Union and also of the Medical and Physical Society of Bombay. He did excellent work in the recent plague epidemic in Bombay. It is believed that the severe physical labor he undertook in connection with plague work and in the management and control of a special plague and fever hospital which he personally organised, was the immediate cause of constitutional break-down which brought on fever and his untimely end. His funeral was attended by thousands of his own countrymen and fellow townsmen and by almost the whole body of the local medical profession of Bombay.

The Council unanimously adopted the following resolution:—The Council of the Indian Medical Association most deeply mourns the sad and untimely death of Dr. K. N. BAHADURJI, and records its sincere esteem of his brilliant talents and of his zeal and devotion to the best and highest interests of the medical profession of India. It recognises in his unfortunate death the loss of a brother who was a leader among his brethren, by virtue of exceptional merit and of a blameless character. The Council desires to express its earnest sympathy with his bereaved relatives, to whom it requests the Secretary to forward a copy of this resolution.

With a vote of thanks to the Chair the proceedings were closed.

MEDICAL EDUCATION IN INDIA.

THE REPLY OF THE MADRAS MEDICAL COLLEGE COUNCIL TO THE INDIAN MEDICAL ASSOCIATION.

It is fortunately not often that we have to deal with such an unsatisfactory, misleading and autocratic official communication, as that which emanates from the Medical College Council of Madras, in reply to the letter of the Indian Medical Association on the subject of Reform in Medical Education, which was addressed to the Chief Secretary of the Government of Madras, on the 20th May, 1898. The full text of the Government Letter in which the College Council's offensive paragraph is embodied, is published in this issue, in the Association's Report.

The Madras Medical College Council's reply is couched in the following terms: "The council being of opinion that the Indian Medical Association is a body in no way representative of medical opinion in India or even in Calcutta, and in view of the fact that Dr. WALLACE's letter contains such glaring inaccuracies and misstatements (especially as regards the standards of professional education and examination in Madras), consider that no useful purpose would be subserved by detailed discussion of the points raised in Dr. WALLACE's letter."

It is a striking commentary on the small amount of interest that is taken in the subject of medical reform, that the Government of Madras should be content to accept this reply as it stands, without further inquiry or explanation of any kind.

It is curious too, that the Medical College Council should be put in the position of pronouncing judgment upon their own case, though at the same time it must be remembered that the remarks of the Indian Medical Association, far from being directed mainly at Madras, touched only in the briefest manner on the system of medical education prevailing there.

No wiser method could be devised for white-washing government systems and government officials than the far too common one of referring all controversial questions for the decision of the very officials, whose department or conduct is the subject of dispute.

An excellent example of this occurred not long ago in Calcutta, when the notoriously unsatisfactory condition of the European General Hospital rendered a Government inquiry imperative. What was the surprise of every one to find that the President of the Court was the Head of the Hospital, and that for members he was thoughtfully provided with the majority of his staff?

That inquiries of this kind cannot be impartial, goes without saying.

But to return to the College Council's reply, we first note as strong evidence of the prejudice underlying it, the fact, that not content with confining themselves to their proper domain, Madras, they *ultra vires*, go out of their way to make it more or less comprehensive for the whole of India.

The reply contains two statements and an expression of opinion; 1. That the Indian Medical Association does not represent medical opinion in India or even in Calcutta; 2. That the letter of the Association is full of glaring inaccuracies and misstatements, and the opinion is expressed that no useful purpose would be gained by discussing it.

Now these two statements we must characterise as misleading and false. With the first we shall deal presently, the second we will consider at once.

From the way this statement is worded, it is evidently intended to convey the impression that there are a large number of inaccuracies and misstatements in the Association's letter, and that these inaccuracies and misstatements not only relate to Madras, as is specifically stated, but more or less to the whole of India.

As we have said, the College Council were not asked to reply for the whole of India, and nothing but prejudice or pique on their part could have induced them to bring in this side allusion, in support of which, they do not bring forward one particle of evidence.

In as far as Madras itself is concerned, we turn from the vague statement of the College Council to the letter from Surgeon-Major General C. SIBTHORPE, C.B., which precedes it, to discover what support there is for this sweeping charge of inaccuracy, and to our astonishment we can only find one point on which the accuracy of the Association's letter is impugned.

It appears that the Association was wrong in stating that the matriculation opens the way to the L. M. & S. degree, and that the First Arts Examination is necessary.

Here is the whole ground for the accusation of inaccuracy. But when we further find that this change is a recent innovation, one of many which have been adopted, we think we are justified in saying that the accusation

for all practical purposes falls to the ground, and that it should never have been made.

Surgeon General SIRTHORPE's letter is for the most part pleasant reading. It shows clearly that the necessity for reform has been fully recognised in Madras, and that steps have been taken in that direction. Far from opposing, it forms the strongest justification of the action that has been taken by the Association.

From it we learn that schemes for the re-organization of the Madras Medical College and Schools have been drawn up and partly disposed of that "all possible steps are being taken to improve the tone of medical education in this presidency."

That "We have no private schools which grant their own diplomas. Such a system is certainly pernicious and ought not to be tolerated."

That with regard to the Hospital Assistant Class, "the system in force in Madras practically meets all the recommendations of the Association in this respect."

Yet in spite of all this evidence of their own activity, all this evidence to show that the question of reform in medical education has pressed upon them and won their earnest attention, the College Council go out of their way to stultify themselves, and to declare that the very subjects to which they have devoted so much time and consideration are unworthy of being discussed!

Surely only prejudice or pique could have led to such a wrong-headed statement.

It would have been more courteous and more truthful if the College Council had openly acknowledged the importance of the subjects dealt with in the letter of the Indian Medical Association, and pointed to the steps already made by them in this direction.

With reference to the question of the formation of a body comparable to the General Medical Council to supervise education and protect the public from the dealings of unqualified persons, we regret that Surgeon Major General SIRTHORPE should have disfigured his remarks by such an egotistical and wantonly insulting statement as that, "there are so few medical men outside the government service, who would be worth being placed on it." It would have been better for him if he could have concealed his personal prejudices and proclivities under a more suave exterior. It hardly becomes Dr. SIRTHORPE as the head of a large educational system, to thus decry the value of his own teaching, by boasting of its incapability of turning out good men.

He might remember that good teachers make good scholars.

The statement is however too obviously false and one sided to be worth refuting at length.

"Such a Council" he says, "would not in my opinion be of much advantage. It will, I think serve the purpose in view, if the universities are given disciplinary power over their graduates." Yes certainly they ought to have this power, but how would that effect the numerous diplomates of the private schools which are constantly on the increase, and how could it tend to suppress the unlicensed practitioners?

These points are unexplained!

The Council, we note, says that the Indian Medical Association does not represent medical opinion in India or even in Calcutta. Such a statement is very easily made, and is only what might have been expected from such a body as the Madras Medical College Council.

It is obviously equally easily and more truthfully denied and disproved. A glance at the latest Annual Report of the Association would prove the utter worthlessness and falsity of this statement. The enormous list of the Association's Membership, and the fact that this list embraces every section of the local profession, is the best refutation of this prejudiced assertion.

Of course the Association does not pretend to represent the opinion of the limited number of medical men holding official positions in the Commissioned Government Services; they are well able to look after themselves, but it is their very exclusiveness and their lack of sympathy with all their non-official brethren that has called into existence, and made necessary, such a body as the Indian Medical Association.

There is a large number of private practitioners throughout the length and breadth of the land, a body of men that is increasing in size and importance every day, whose interests are put on one side, and whose prospects are thwarted; it is this body of independent private practitioners and the members of the Local Medical Services, which the Association claims to represent, and the questions it takes up, are taken up and pushed forward, solely in their interests and in the best interests of the public.

CONTRA-INDICATIONS FOR THE BICYCLE.

MOST medical men, says the *International Medical Magazine* whether cyclists or not, will agree with E. B. TURNER when he asserts that the following conditions form absolute contra-indications to cycling: (1) pregnancy (2) menstruation, (3) the three months following parturition, and (4) before the age of seven years. Further, the morbid states of the heart, lungs, kidneys and brain, which contra-indicate other forms of muscular exercise, will also preclude cycling. Most writers are agreed that acute pelvic inflammation, recent displacements of the pelvic organs, fibromyomata, ovarian cysts and hæmatoceles form distinct contra-indications to cycling but it may be well here to give the list of gynecological troubles which Fauquez (12) has drawn up and in the presence of which the exercise must be abandoned. It is as follows; (1) amenorrhœa, in connection with pulmonary phthisis, cancerous affections, diabetes and organic diseases of the heart or kidneys; (2) metrorrhagia, or excessive menstruation, (3) inflammation of the uterus and its appendages, acute metritis, painful chronic metritis, hæmorrhagic or purulent endometritis, salpingitis, ovaritis, salpingo ovaritis, perimetritis, pelvic cellulitis, and pelvic abscess, (4) pelvic hæmatocele, and uterine fibroids during the hæmorrhagic period; and (5) in vulvitis and vaginitis before complete cure has been effected. With regard to certain other gynecological affections, such as minor degrees of prolapse, chronic pelvic inflammation, subinvolution, and uterine retroversions and anteversions, medical opinion is not yet fully formed; in instances such as these named, the gynecologist ought to make a complete survey of each individual case, and form his own opinion thereupon. This, however, seems to be certain: that women wearing a well fitting pessary are not debarred from cycling. Women of advancing years, especially if near the menopause, should be extremely careful with regard to this form of exercise.

CURRENTS AND NEWS

TREATMENT OF RABIES BY THE INJECTION OF NORMAL NERVE SUBSTANCE.

THE following is the full text of a very important note by M. V. BARRIS of Bucharest which was recently read before the French Academy of Science at Paris.

"In 1889, I observed that persons bitten by rabid animals who were subjects of neurasthenia, epilepsy or melancholy, were, after undergoing Pasteur's treatment, partly cured of these diseases also. From this observation I endeavoured to treat cases of neurasthenia, melancholia, and epilepsy by injections of nervous substances, especially with the spinal cord of sheep and rabbits.

My regretted friend CONSTANTIN PAUL declared to the Academy of Medicine at Paris in February 1892, that he was convinced of the good effect of these injections which he described as the procedure of Professor BARRIS.

Applying this process himself at Paris, he had obtained a series of remarkable results, which he lost no time in communicating to the Academy of Medicine, while I on my side published my results in the *Deutsche Medicinische Wochenschrift*.

The illness and death of my friend having interrupted the clinical study of this procedure, it is only recently that its study has been again taken up in a scientific and experimental manner.

I had already suspected that the nerve substance ought to possess to a certain extent the power of combatting the infections which attack the nervous system and especially the nerve cells. Thus on examining the different organs of animals immunised against rabies, I showed that the antirabic substance in those animals only existed in the blood and nervous system, especially in the cerebro-spinal fluid.

I then showed that at a certain time the blood contains antirabic substances, while the nervous system does not.

In localising the lesions of rabies in the nerve cells of the bulb and of the spinal marrow and in considering the virulence of the grey matter in this disease, I was led to admit that the virus of rabies was localised in these cells and that these lesions and the symptoms of rabies stand to each other in the relation of cause and effect.

In 1889, I discovered the property which the serum of immunised animals possesses in the cure of rabies, and as I wanted to antagonise experimentally the action of the virus of rabies and the antirabic serum, it was necessary to find out the source of the latter.

As it had been demonstrated for tetanus that the tetanus toxin is attracted to the same nerve cells, and that these cells secrete an anti-tetanic substance, it was foreseen that the nerve cell by means of this important function and by its stability should have the power of resisting direct attacks from the virus of rabies.

In these cases it is necessary to suppose that the normal nerve cell contains, or secretes a substance, which up to a certain point can oppose the rabic infection.

I have therefore tried to prevent or cure rabies by my method, that is by the subcutaneous injection of a certain quantity of the nerve substance of the bulb and spinal marrow of healthy animals. First I tried in collaboration with M. BINGHAM, if we could paralyse (neutralise) the virus experimentally with the nerve substance, but while we found that one part of the blood of dogs, which was most highly immunised, could paralyse up to 50 parts of the virus, one part of the bulbar substance from a sheep or a rabbit did not succeed in paralyzing one part of the virus. And even 10 parts

of the bulbar substance had no appreciable effect upon one part of the fixed virus.

However, experimenting with M. BINGHAM, I succeeded in obtaining a decided action, preventive or curative, with the nerve substance against the virus of rabies, by means of using a sufficiently large quantity of the nerve substance and not too strong a virus.

Thus on inoculating, by trephining, dogs with a virus obtained from rabbits after two days passage, and treating three of the dogs for ten days with daily injections of 5 grammes of an emulsion obtained from the spinal cord of a healthy sheep, the control animal died on the 15th day of rabies, one of the treated dogs died on the 30th day of rabies and the other two recovered.

In repeating this experiment upon four dogs treated alike, only one recovered; but, in commencing the injections three days before the cranial infection with three dogs, and in infecting a control animal at the same time, the last succumbed to rabies on the 18th day, while the other three recovered.

As two months have elapsed since these experiments were carried out, they may be regarded as conclusive.

With rabbits the results have been much less decisive, which is explained by the fact that it is rarely possible to save these animals, even by PASTEUR'S method if the treatment is begun after trephining.

We are continuing these interesting experiments, under altered conditions of infection, but we are anxious to publish these preliminary results which prove, that it is possible to antagonise rabies by injections of nerve substance derived from the bulbs of sheep, which are healthy and previously untreated.

By the results obtained by WUNDERMANN and TAKAKI, in tetanus, as well as those obtained by VIDAL, MARICATIDIS, etc., in strychnine poisoning, as well as by the results above mentioned, my procedure of treating certain maladies of the nervous system by the injection of the normal substance of the bulb of sheep has acquired a solid experimental basis.

Further our experiments have proved, that the substances contained in the bulb and which antagonise the infection of rabies and of tetanus, act upon certain toxins, certain alkaloids, certain poisons differing in character, in such a manner that there can be no doubt that my procedures may have a beneficial action in different nervous diseases of a toxic or infectious nature, as well as in those diseases in which favourable results were obtained by CONSTANTIN PAUL and myself.

PRESENT POSITION OF VACCINATION.

THE following remarks were made at the Annual Meeting of the British Medical Association at Edinburgh by the President, Sir T. GRAINGER STEWART, MD., LL.D., F.R.S.

With scarcely a dissentient voice the medical profession recognises the transcendent value of vaccination. A Royal Commission laboured for many years and at last reported unequivocally in favour of that treatment. But with a determination which would be admirable if it were not so disastrous, a comparatively small group of men set themselves to opposing and maligning the process, belittling its advantages and magnifying and multiplying the slight risks which attend it. To these a considerable section of the English public have given heed rather than to the medical profession—I speak advisedly of English public for, as Mr. BALFOUR has pointed out, the public of Scotland remains loyal to medical opinion. But from the attitude of certain districts in England it comes about that the greatest discovery in practical medicine, although it had its native home in Britain, is less efficiently carried out here

the most important parts of the Continent. In Germany compulsory vaccination has practically disappeared; there has been no death since 1874 in the whole of the vast German army since vaccination was made compulsory. In 1855 and 1857 Acts were passed for compulsory vaccination in England. These Acts have been the constant object of attack by the anti-vaccination propaganda. The Vaccination Commission was a result of these attacks. It included active opponents and active supporters of the process, with some members who were understood to take up the inquiry without any definite pre-formed opinion. After seven years' labour they gave in their report. By a majority of 11 to 2 they found that vaccination was a valuable preventive of small-pox; that the process could not be safely abandoned and replaced by other precautions; and that while some alleged dangers are real, they are in truth unimportant in relation to the extent of vaccination work done and are diminishing under the better precautions of the present day. More than a year elapsed before legislation was attempted and the Bill was introduced of which the third reading occupied the House of Commons to-day. That Bill contained good provisions in the way of postponing the date of compulsory vaccination of infants, providing for the treatment being carried out at home, the supplying of calf lymph, and taking advantage of Dr. COPEMAN'S valuable discoveries regarding the special security afforded by glycerinated lymph. But the Bill made one disastrous omission. It proposed nothing in the way of revaccination. Now, experience has proved that the protection afforded by the process requires to be renewed from time to time and has amply shown that here, where it has been tried in many ways, as well as in Germany, where it has been since 1874 compulsory, repetition of the process secures an almost absolute immunity. It is in my opinion, and I am sure in that of almost the whole profession, profoundly to be regretted that the Bill contained no proposal in regard to revaccination. It is grievous to think that we lag behind and are deprived of securities which would be of such value and might so readily be obtained. But if this was a disastrous omission the Bill as it leaves the House of Commons shows another defect, for in the course of last week's debate it was decided that "no parent or other person shall be liable to any penalty under the Vaccination Act 1867, if he satisfies two justices in petty sessions that he conscientiously believes that vaccination would be prejudicial to the health of the child."

"The first remark that I would make is that this clause admits the status of the "conscientious objector" and gives him rights and privileges. An analysis of conscience is always attractive to a Scotsman, but I refrain from attempting to forecast how the process would work out either in regard to that of the "conscientious objector" or those of the justices of the petty sessions. But the right of a person to act according to his conscience is one, which a democracy is bound to protect. Only whenever it is distinctly proved that the result of conscientious objections is really dangerous to the well-being both of the individual concerned and of the community, the community is, in my judgement, entitled to set aside the conscientious objections and to insist upon obedience. The Commissioners, who acted as a jury for the nation in this matter, are satisfied that the abandonment of vaccination would inevitably lead to formidable evils. It seems, therefore, to me that the plea of conscientious objection affords no logical ground for resistance to the law. The second remark which I would make is to inquire what the term "conscientious objector" might be made of cover. This is no easy task, but it is safe to say that it would in-

clude a great deal more than the mere conscientious objector should be. And when a man has been so educated, we may say that conscientious objections springing up in early years. In questions of education they might make themselves heard. In regard to the payment of taxes conscientious objections, if once admitted, would no doubt spread with great rapidity; and in regard to sanitary laws, the liquor laws, and many other subjects so conscientious examples might soon assert themselves in somewhat startling ways. But apart from speculative opinions let us see what different parties are saying about the practical result of the clause. Mr. CHAPLIN, who did his best to stand to his ground, says that the administration of compulsory vaccination in the future will be absolutely impracticable and no Ministry will be able to enforce it. Many share his opinion and regard the outlook as gloomy in the extreme.

"I wish that the Legislature would boldly accept the principle that as it is mainly guided by the opinion of lawyers as to legal questions, by those of soldiers in matters military, by practical seamen and engineers in matters concerning their department, so in medical questions they would look for guidance to the medical profession, and give effect to its matured opinion. Then we should have less difficulty about the question of vaccination, or that the treatment of scurvy, or the prevention of the risks attending certain callings, such as those that expose the workers to lead poisoning or to poisoning by phosphorus, and we would soon find the Statute Book enriched by further beneficent enactments which would save multitudes of lives and immensely diminish sickness and suffering."

SUB-SOIL DRAINAGE AND PUBLIC HEALTH.

AN important addition has been made to our knowledge of the influence exerted upon health by the condition of the soil, in a paper entitled, "The effects of Drying of the Soil upon the Public Health of Buenos Ayres," by Dr. JAMES T. B. DAVISON which appeared in the *Lancet*, of August 6th.

The diseases investigated by Dr. DAVISON are tuberculosis, pulmonary, laryngeal, and mesenteric, tetanus, and pneumonia, broncho-pneumonia and pleuro-pneumonia.

With reference to Tuberculosis his results tally with those obtained in the early sixties by Dr. BUCHANAN in England and Dr. BOWDITCH in America, that drying the soil diminishes the prevalence of tuberculosis. In Buenos Ayres in the years tabulated, from 1873 to 1896 inclusive there was a steady fall in the mortality caused by this disease from 3.8 to 1.6 per 1000.

The fall in the mortality from tetanus was equally steady, but much more extensive, for while in the years 1873 to 1876 we find the death-rate ranging from 2.5 to 4.2 per 1,000 in 1884, '95, and '96 it has been reduced almost to the vanishing point, viz. 0.2 per 1,000.

The conditions are different however when we come to Pneumonia, for in this case the mortality has increased, "the drying of the soil and sub-soil in Buenos Ayres has been the means of increasing the mortality from pneumonia." The increase has been from about 1.6 to 2.6 per 1000, the mortality is marked by great irregularity from year to year.

On this part of the subject Dr. DAVISON says, "regarding pneumonias, the relation between the increase of this group of diseases is too evident to be ascribed to mere coincidence. Several have been the observers who in different countries have noted this relation, but their conclusions have been impugned and sometimes with statistics which have been gathered monthly. The question is yet *sub judice*. The statistics which I adduce in this paper have the value that they cover an epoch of a quarter of a century, and they

have been made which cannot be taken into account in which the results of the observations were carried out separately in the different elements, so that the effects of these upon the public health could easily be observed. Changes in the subsoil take place with great slowness and their effects upon the public health are likewise slow and prolonged. In order to study accurately the relation between subsoil and public health years and not months must cover the periods of observation."

In this paper it is to be regretted that we are not furnished with any precise means of estimating the relative dryness of the soil from year to year, and are told nothing about the depth of the subsoil water either at the beginning or end of the period, or during any of the intervening years; this omission, regrettable as it is considering the importance of the subject, was no doubt unavoidable as it is highly probable that no records were kept.

The conclusion that the soil did become drier from year to year is based, not upon any actual estimation of its dampness or otherwise, but upon the fact that from the time works were constructed for carrying off the excessive rainfall, we are told that "the city was provided with sanitary and other works destined to remove its rainfall. These sanitary works were not all constructed at the same time. This construction was carried out in these periods and this has made possible the appreciation of the effects produced separately by each of the several sanitary factors which were brought into activity."

This is a very rough basis for accurate observation, but when the question of subsoil water is concerned anything better is rarely attainable.

Measurement of sub-soil water levels hardly comes within the province of the physician, and other people do not as yet appear to have thoroughly learned their value, it is for this reason that the influence of soil dampness upon health is so imperfectly understood.

It should be the duty of every large town and city to keep accurate measurements of the sub-soil water levels, as well as of the various meteorological phenomena, so that they may be at hand when their evidence is required in any investigation into disease.

AN ANALYSIS OF PLAGUE CASES IN CALCUTTA.

AN interesting analysis of the cases of so-called Plague which occurred in Calcutta up to the 18th of August, has been published by Mr NALIN BIHARI SINGAR, a Municipal Commissioner of Calcutta.

This report serves to corroborate many of the statements and arguments which have from time to time appeared in our Editorials on the subject.

On the 18th August, the disease had been in Calcutta for 18 weeks, and during this period, cases were returned from 20 out of the 25 Wards into which the city is divided. It is thus seen that the disease is spread broad-cast over a considerable area and not limited to any particular locality.

The total number of cases returned in the time specified was 210, of these 174 died, 29 recovered and 7 were still under treatment. Yet out of these 210 cases it is stated that "hardly a single case is clearly traceable to contact with another, a fact which makes one extremely sceptical as to the contagious character of the disease such as it has appeared in Calcutta." It is also noted that there are only 10 premises which show the occurrence of more than one case in each.

Full particulars are given of the cases that occurred in each of these 10 premises, and it is clearly shown that the theory of infection is altogether inadmissible or extremely improbable.

and the author denies the greatest cause for the occurrence of which he has carried out his appointed task.

So far everything tends more and more to bear out the doubts we expressed from the very beginning as to the accuracy of the official diagnosis. The Plague, if plague it be, has come in such a questionable shape, it has left behind it so many of its usual characteristics and presents so many anomalies, that the tendency to question its identity is growing stronger every day.

"The most striking fact," we read in the analysis before us, "in regard to the present outbreak of plague in Calcutta, is that although the disease has been in our midst for 18 weeks, the total number of attacks has been only 210, while in Bombay, Karachi, and Poona, during the same period of 18 weeks, from the detection of the first case, the numbers were 4,123, 3,456 and 2,224, respectively."

The reason usually assigned for this difference, by those who are interested in keeping the city within the meshes of the plague regulations and the other disabilities it at present enjoys, is that the season was unfavourable.

This excuse is based on evidence altogether too unsubstantial to be worthy of a moment's credence. Absolutely no case has been made out in support of the contention that the occurrence and spread of plague are closely connected with, and largely influenced by meteorological conditions.

It is most discreditable that we should be constantly told to wait until next cold weather to see whether the present disease deserts its present sporadic form and becomes epidemic, as if this were the only test which the Government of the country has in its power to employ for the identification of true plague.

At the end of his report, Mr NALIN BIHARI SINGAR gives us a carefully constructed chart, showing by weeks the number of cases, number of deaths, temperature, barometric pressure, humidity and rainfall. We cannot however trace any connection between these atmospheric conditions and the number of cases. In fact the two weeks in which the greatest number of cases occurred, viz, the last week in April and the first week in July are utterly unlike each other in their various meteorological phenomena.

GONDAL ADMINISTRATION REPORT FOR 1897-98.

It affords us considerable pleasure to be able to review so highly satisfactory a Report as the one before us. The Independent State of Gondal has an area of 1024 square miles, a population of nearly 300,000, and an annual revenue of about Rs 15,00,000, while the tribute paid amounts to Rs. 1,10,721. It is interesting to note that its enlightened Ruler, Sir BHAGVAT SINGHJI, M.D., F.R.C.P., L.L.D. the Thakoor Sahib and his Rames were both in England (or rather Scotland) during the Diamond Jubilee celebrations, and that besides taking part in the loyal demonstrations His Highness was fortunate enough to be the recipient of the order of G. C. I. E. at the hands of Her Majesty, concerning which the *Lancet* had some commendatory remarks at the time. Three of His Highness' children are enjoying the best education at Home, the Heir-apparent making satisfactory progress with his studies at Eton, while the younger son and a daughter are doing the same at the Scottish capital. The young Princess had to undergo for the second time a surgical operation on her neck, with a hopeful result we are glad to learn.

The past year has been one of continued progress. The building of the Grania College is all but completed, along with the Principal's bungalow, and a large sum has been

The Government of Bombay have been very anxious to see that the health of the town of Gondal was maintained, while a large sum was expended in the construction of a railway line, and an extensive place of land reclaimed for a horse-breeding paddock. Although the State experienced no failure of harvest, Relief works were opened during the time of general scarcity, and the needs of the poor were relieved in a variety of ways. It is worthy of note that the total gross revenue increased by about one lakh, with a corresponding expenditure, the latter being mainly due to relief works and grain compensation. The Police are to be congratulated on the breaking up of a notorious band of outlaws, the ringleaders of which were killed.

Consequent on the resurgence of the Plague in Bombay, the swiftest and most energetic precautionary measures were adopted at Gondal. Temporary sheds were erected, the Durbar buildings were whitewashed. Passengers arriving by Railway and travellers by ordinary roads were examined, and those who came from infected places were segregated for ten days in Observation Camps. Passengers and their luggage were disinfected and all this with the most satisfactory results. Since the creation of the Gondal Health Department, the sanitation of the town has been receiving the greatest attention.

The number of births registered in the town of Gondal, exclusive of still-born, was 650 against 557 in the preceding year; of these 356 were males and 294 females, against 285 and 273 respectively last year. The birth rate for the year was 42.8 per 1000 population, against 35.3 last year. The total number of deaths during the year was 572 against 462, giving an increase of 110, and a death-rate of 37.25 against 30.1 in the preceding year. The excess of mortality is attributed to the prevalence of malarial fevers. During the year the greatest number of deaths (69) occurred in November and the least (26) in March, while in the previous year the largest number (87) occurred in July and the least (20) in March.

There are two Hospitals and four Dispensaries—one of these a Travelling Dispensary in the State. The total number of patients treated during the year was 47,742 against 49,856 in 1896-97. Of these 1,541 were in-door and 46,201 out-door patients, as contrasted with 1,631 and 47,825 respectively in the year previous. Of the in-door patients 1208 were cured, 160 relieved, 68 discharged otherwise and 58 died, giving a ratio of 3.4 deaths per cent of the total treated or 0.5 per cent more than in 1896-97. The daily average sick was 71.86 (59.90 men, 8.76 women and 2.7 children) as compared with 65.68 in the previous year. Of the out-door patients, the majority attended personally, while some were represented by friends, and the daily strength was 419.74 against 399.62 in the preceding year. The total number of beds available was the same as last year, viz. 101 (79 for males and 22 for females). Of the total in-door and out-door patients treated, there were 22,185 men, 8,924 women and 16,690 children. Distributed according to castes there were 32,490 Hindus, 14,440 Mussalmans, 98 Parsis, 132 Native Christians and 582 other castes.

Indeed not only H. H. The Thakoor Sahib himself, but the worthy Dewan, Mr. BANAJI MEHWANJI, and the energetic Health Officer, Dr. HARI BHOGAJI, alike deserve to be warmly congratulated on the state of things which has led to so excellent and readable an account of their stewardship.

The following statement of the number of cases of Plague treated at the Hospital for venereal diseases of the Bombay Army, from 1860 to the latest available returns. They are abstracted from Parliament Returns 825 of 1868; 274 of 1894; 133 of 1895; 140 of 1897; and [C—6559] of 1897.

Year.	Admissions per 1000.	Remarks.
1860	309	
1861	395	
1862	376	
1863	341	
1864	348	C. D. Act of 1864, applicable to 11 places, but scarcely applied at all.
1865	341	
1866	321	
1867	350	C. D. Act of 1866, applicable to 12 places, but in very partial operation.
1868	345	
1869	318	
1870	301	
1871	301	
1872	302	
1873†	177	
1874	146	C. D. Acts of 1866-69, applicable to 15 places, and in full operation.
1875	139	
1876	146	
1877	158	Statistics 1878-1879 unreliable. See note below.
1878	175	
1879†	179	
1880	246	
1881	246	
1882	246	
1883	260	
1884	271	C. D. Acts suspended.
1885	275	
1886	267	
1887	258	
1888	224	
1889	212	
1890	212	
1891	197	C. D. Acts abolished.
1892	201	
1893	195	
1894	182	
1895	174	
1896	158	

† Statistics for 1873 to 1879 are officially stated in Parliamentary Paper 509 of 1894 to be unreliable, owing to the issue of an Order by Lord CARDWELL, October, 1873, which is said to have resulted in "concealment of disease to avoid loss of pay." It was cancelled 27th November, 1879.

The above figures are illustrated by the following diagram:—

In the face of these figures, how is it possible for anyone to maintain that the C. D. Acts were of any advantage in diminishing disease?

VENEREAL DISEASE IN INDIA

During the debate on the Indian Budget in Parliament, Mr. JAMES BRIDGES asked the question and got a reply from the Secretary of State for India, who said the hon. member must recollect that when the present Government came into office they found a most remarkable and almost incredible state of things. A certain body of ladies and gentlemen, with the desire of promoting social purity and public morality, had actually contrived in their zeal that it should be enacted in India that venereal disease should be the only disease which should be exempted from the regulations applicable to all other contagious diseases. The condition of things seemed to him absolutely intolerable. He had always looked on this not as a military but as a national question. They had to promote the health of the people. They had a magnificent army in India—an army capable of great performances. It must not be forgotten that during the past two years our soldiers in India had distinguished themselves on the frontier and elsewhere. These soldiers were all more or less young soldiers and when the *Warren Hastings* transport was in danger, many of these young soldiers stood for hours in a sinking ship and not one of them moved until every woman and child on board was removed. Therefore, he said, they were young men full of chivalrous instincts towards the weaker sex, and he did think it was an absolute disgrace that a condition of things should be allowed to exist in India whereby this superb army should become a sewer for the transmission of the worst of contagious diseases. They thought it was necessary to try to do something to mitigate the ill effects which had existed, and what they proposed was simply to put venereal disease on exactly the same footing as other contagious diseases. He expressly laid down certain conditions which should not be infringed. As a natural consequence of their determination they had to repeal the Act which prevented this disease from being put on the same footing as other contagious diseases. He had taken the utmost care to test the accuracy of the figures relating to India and he could assure the hon. member that there was indisputable evidence to show that the removal of all regulations had largely increased the disease in India and that its intensity had also been greatly augmented. Certain reforms had been suggested and adopted relating to inspection and to measures for preventing the concealment of disease. Again, memoranda had been issued by the Commander-in-Chief, both in India and at home, impressing upon regimental officers the necessity of giving good advice to young soldiers, pointing out the evil consequences which ensued from giving way to vicious habits and directing that in the recommendations for promotion care should be taken to see that those selected were free from vicious habits. It would be seen, therefore, that not only had he kept faith in everything he had undertaken to do, but he had gone even beyond it. He looked upon this question as one of national importance and one which must not be looked at from a purely political point of view. He believed the regulations which had been laid down could be justified from every aspect, that they were in accordance with the Christian precept which exhorted them to heal the sick, and that they were dictated by the common principles of humanity.

THE SECTION OF TROPICAL DISEASES.

AT THE MEETING OF THE BRITISH MEDICAL ASSOCIATION AT EDINBURGH.

THE 66th Annual Meeting of the British Medical Association was remarkable for the fact that for the first time it included a Section of Tropical Medicine. Dr. MANSON who delivered the inaugural address had no difficulty in showing

that there were plenty of people who, by instituting the new department and so making that new section with increase in interest from year to year.

Dr. MANSON pointed to three classes of functions which the new Section ought to fulfil.

First the attention and organisation of the five or six thousand British practitioners who, more or less directly, are interested in tropical practice.

Secondly, the improvement of Education in tropical medicine.

Thirdly, the discussion of the problems of tropical disease.

Dr. MANSON then briefly alluded to some of the subjects which particularly required elucidation, and to some of the latest theories that have been propounded.

The following papers were read in the Section on Beriberi by Dr. CONOLLY NORMAN (Superintendent, Richmond County Asylum, Dublin).

On Pellagra, by Dr. SANDWITH (Cairo).

The cause of Yellow Fever, by Inspector-General TURNBULL, R. N.

Dr. THOMSON (Ceylon) discussed the treatment of cholera, and Dr. MANSON showed diagrams and specimens of the Malaria parasite.

Professor W. J. SIMPSON, Late Calcutta Health Officer read a paper on Plague in India.

A paper by Professor W. M. HAFKINS and Surgeon-Major BANNERMAN I. M. S. on the Testing of the Plague Prophylactic in Plague-Stricken Communities in India was read.

Surgeon-Colonel DIMMOCK, I.M.S. gave an account of the Measures adopted for Dispelling Plague in Bombay, and some more plague literature was contributed by Surgeon-Colonel ARNOTT.

The following message was sent by the Section to Surgeon-Major ROSS I. M. S.

That the Tropical Disease Section send a message of congratulation to Surgeon-Major RONALD ROSS in Calcutta for the excellent work he has done, and is doing, in connection with the extra-corporeal life of the malarial parasite, and thank Dr. PATRICK MANSON for his careful exposition of ROSS' work, and for the part he played in conjunction with ROSS in bringing about the important results stated in Dr. MANSON's lecture."

Altogether the Section, if it is not responsible for anything very startling, may be said to have opened very satisfactorily.

BACTERIOLOGICAL LABORATORIES IN INDIA.

WE take the following from the *Lancet*, as it will interest our readers, being written by our worthy Health Officer, Dr. J. NIELD COOK:—

SIR,—In a recent issue of the *Lancet* I read the following:—

"When the recent outbreak of plague occurred at Calcutta it was a matter of obvious importance that the exact nature of the disease should be determined with the least practicable delay. Happily for the Government of Bengal, the services of M. HAFKINS were available and he was able to report, as the result of a bacteriological examination, that the outbreak was due to true bubonic plague. We have heard a great deal about the establishment of bacteriological institutes or laboratories in India; now here was an occasion in which a bacteriological laboratory in Bengal would have been of the greatest use, and we are glad to notice that the *Englishman* of Calcutta has called attention to the subject."

"The credit of the Municipal Commissioners of Calcutta be it said that, on the representations of the late medical officer of health, Dr. SIMPSON, they provided and equipped a bacteriological laboratory, so that I was able to work out my first case of plague bacteriologically. I obtained the bacillus in pure culture and sent two agar slopes to Professor HAFKINS in Bombay for confirmation of my results, as I was advised that Government would not take the responsible

was of assuming the city an infected area without the opinion of a surgeon. The post-mortem examination was absolutely typical of plague. I know of no other disease which produces such pathological features—large hemorrhages extending from an affected femoral gland up into the abdomen behind the peritoneum and half way down the thigh, and petechial hemorrhages on the heart and other viscera. I made cultures from the gland, spleen and heart's blood. From the cultures I inoculated two guinea-pigs subcutaneously in the thigh. Both died four days later with buboes and hemorrhages and I got the same bacillus in culture and under the microscope from them. I also obtained it growing in stalactites from ghee (clarified butter) floating on the surface of a flask of bouillon. So I had pathological microscopical, and cultural proof, which was further supported by the clinical history I had obtained, before I heard from Professor HAFKIN. I may add that my investigations were closely followed by Surgeon-Colonel T. M. HENDLEY, C.I.M., Inspector-General of Civil Hospitals, and Surgeon-Major H. J. DRYDEN, F.R.C.S., Eng., Sanitary Commissioner, who were satisfied with the accuracy of my results."

VENEREAL DISEASE IN INDIA.

SAYS the *British Medical Journal*—"The General Order as to means for checking venereal disease among British troops in India issued by the Commander-in-Chief in India was laid on the table of the House of Commons, on August 9th. It was founded upon Lord GEORGE HAMILTON's well-known despatch, and according to the summary of its contents which has been published in the *Times* it does not appear to contain any novel points. Officers are advised to exercise their influence in the cause of morality, and it is justly added that soldiers listen with attention to those, and it might have been added only those, whom they respect and who can speak to them from the standpoint of higher education, of blameless life, or of technical knowledge. The famous idea of giving didactic instruction takes form in the suggestion that selected combatant and medical officers should be invited to deliver lectures to the men on the moral and physical degradation which is almost certain to result from misconduct. It is impossible to feel very sanguine about the success which is likely to attend this propaganda. But it may do some good, and it certainly ought to be honestly tried. The medical profession undoubtedly has a duty in this matter, and probably there is no officer to whom the men would more readily listen on such a subject, without false shame and bravado, than to the soldier doctor, when once they have got to know him. The present rate of invaliding is a scandal to the army, rank and file, and the recommendation that men who are again and again admitted for fresh attacks of local venereal disease should be subjected to all the restrictions of discipline will be approved by everybody, only there must be no confusion on the head. A man who is admitted for fresh manifestations of the constitutional disease acquired perhaps long before, should not be penalised, otherwise there will be a temptation to conceal the facts. This would be a misfortune, and would have the inevitable result of increasing permanent invaliding, for thorough and long continued treatment is above all things necessary in syphilis. It is to be hoped that this aspect of the question will be kept well in view."

THE HEALTH OF THE FRENCH ARMY SINCE 1892

Attention to sanitary details has left its mark upon the death-rate of the French Army, the years 1896 and 1897 show the lowest figures yet reached.

Small-pox has almost completely disappeared owing to the rigorous application of vaccination and revaccination. In 1876-1877-1878, there was an average of 1000 cases with 100 deaths, since 1894 the mortality has fallen below 10. In 1896 there were 56 cases with 3 deaths, and in 1897 58 cases with one death.

Typhoid Fever—The mortality shows a rapid decrease 1.82 per mille in 1898 to 0.95 per mille in 1896. In 1897, it was 1.05 per mille, the rise was due to the epidemics at Marseilles, Nice and Ostrera.

Diphtheria—The mortality has diminished to a large extent. The number of cases has fallen from 10 per cent in 1888 to 6.1 per cent in 1897. The number of deaths in the last three years, 1895, 96, 97, was 24, 19 and 16 respectively.

Tuberculosis—Is the most deadly disease in the Army, it alone causes more than a fifth of all the deaths.

In the following table is shown the annual death-rate from tuberculosis from 1872 to 1897 inclusive.

Year.	Death-rate p. 1,000.	Year.	Death-rate p. 1,000.
1872	8.97	1895	6.15
1873	8.68	1896	6.41
1874	8.49	1897	5.90
1875	10.55	1898	6.09
1876	10.05	1899	5.99
1877	8.14	1900	5.81
1878	7.56	1901	6.77
1879	7.39	1902	5.59
1880	9.46	1903	5.25
1881	7.80	1904	5.29
1882	7.88	1905	6.08
1883	6.92	1906	4.56
1884	6.12	1907	4.56

PLAGUE IN THE DECCAN.

In Hubli there were reported 2,079 cases and 1,742 deaths up to the 25th August.

In the Belgaum collectorate five talukas have been attacked namely, in Belgaum 12 villages, in Ohikodi one village, in Samppoon 4 villages and in Khanapore six villages.

In Bangalore there were seven deaths up to 29th August. Some panic prevailed and the troops had to be called out to disperse the mob.

The following are the statistics of the Bombay Presidency for the week ending August 26th. Bombay, 175 cases and 165 deaths, Kurrachee, 20 cases and 10 deaths, and Poona, three cases and one death.

In the districts—Broach, 64 cases and 35 deaths, Surat, 80 cases and 57 deaths, Thana, 244 cases and 181 deaths, Ahmednugger, three cases and three deaths, Nasik, 74 cases and 57 deaths, Satara, 114 cases and 81 deaths, Sholapore, 42 cases and 34 deaths, Ratnagiri, one case and no death, Belgaum, 617 cases and 472 deaths, Dharwar, 885 cases and 664 deaths, and Kurrachee, nine cases and eight deaths.

In the Political Agencies—Baroda, 186 cases and 95 deaths; Kathiawar, 179 cases and 108 deaths, Kolhapore, 155 cases and 121 deaths, Cutch, 70 cases and 55 deaths, Sacuin, two cases and two deaths, Akalkot, 33 cases and 26 deaths, and Bhor, 48 cases and 49 deaths.

Total, 8,094 cases and 2,215, deaths, The total mortality up to date exceeds a lakh, the exact number being 100,483.

PLAGUE IN BOMBAY.

The increase in the death-rate from Plague in Bombay continues, and is being watched with considerable uneasiness.

The following table shows the course of the disease during the last 17 weeks.

Week ending—	Mortality	Week ending—	Mortality
10th May	118	12th July	53
17th "	107	19th "	63
24th "	101	26th "	69

This looks as if the disease was waking into activity again, and though it has not as yet attained to a decided epidemic character, it may be on the very eve of doing so.

This compares badly with the record of the two previous years when the plague remained quiescent for about six months. The quiescent period this year has hardly lasted three months, while the death-rate has been constantly much higher than it was last year.

The reasons for this are not apparent, but it would certainly appear as if climatic conditions had not quite so much influence as it has been the fashion to believe.

RAPID CHANGES IN SANITARY APPOINTMENTS IN CALCUTTA.

IN our last number we had to record the transfer of Surgeon-Major BANNERMAN from the post of Special Health Officer of Calcutta and the appointment of Dr. FETTERER in his stead. We have now to report the installation of Surgeon Captain C. R. M. GREEN, F.R.C.S., L.R.C.P., L.S.A., and D.P.H., into this important position. Dr. GREEN qualified in 1885 and obtained the Sanitary Certificate of D. P. H., in 1895, that is just two years ago. We are not aware that Dr. GREEN has done any "special" work in sanitation, but his academic qualifications entitle us to hope that hygienic matters in Calcutta ought to be well served at his hands.

A PLAGUE CONSIDERATION FOR THE MUNICIPAL GOVERNMENT.

At a recent meeting of the Calcutta Municipal Council, Mr Chunder Ghose asked the following question:—

"Having regard to the difference of opinion that is being expressed in the papers and by the people as to the existence of plague in epidemic form in Calcutta, will the Chairman and the Health Officer be kind enough to say if rate-payers and other people who have left the town or who have sent their families and children out of town in consequence of several scares, may be advised to come back in our midst?"

The Chairman stated that the Health Officer considered this to be a matter for private judgment. In his opinion people might be advised to return and to bring back their families and children.

LONDON EXAMINATION RESULTS FOR THE R.A.M.C. AND I.M.S.

The following is the list of successful candidates for commissions in the Royal Army Medical Corps at the recent examination in London:—

Marks	Marks.
F. Warren 2558	G. W. G. Jones ... 2183
J. E. Hodgson ... 2617	J. W. H. Houghton 2117
H. P. W. Barrow ... 2603	H. S. Taylor 2101
M. H. G. Fell 2611	A. L. Scott 1991
T. C. Lauder 2415	J. W. Lenke 1969
J. G. Gill 2292	R. H. Lloyd 1935
W. B. Winkfield ... 2268	D. E. Curme 1892
G. E. Goddard 2211	G. M. Goldsmith ... 1848

The following gentlemen were successful candidates at the competitive examination for the Indian Medical Service held in London on 5th August and following days:—

Marks	Marks
Leicester, J. C. H. ... 3,179	Parker, L. E. L. ... 2,336
Innes, H. 2,858	Ross, T. F. 2,316
Willmore, W. H. ... 2,660	Walker, I. N. 2,278
Hutchinson, L. T. E. 2,604	Kemp, D. O. 2,274
Waller, A. E. 2,553	Roberts, V. H. ... 2,259
Hudson, C. 2,523	Robinson, J. H. ... 2,215
Fleming, A. M. 2,469	Groube, G. P. T. ... 2,131
Craddas, H. M. 2,460	King, G. 2,095
Weinman, E. F. 2,452	Atal, P. P. 2,091
Ward, F. L. 2,411	Pearson, W. McM. 2,027

THE JUNIOR STAFF OF THE CALCUTTA COLLEGE HOSPITAL.

The present incumbents of the residential appointments at the Calcutta Medical College Hospital are Surgeon Captain Robert Bird M.D., Lond. F.R.C.S., Eng. D.P.H. Camb a gentleman with a brilliant academic record, the son of an old I.M.S. Surgeon, who is Resident Surgeon and Physiologist to the College, Surgeon-Major C. H. Evans, M.B., B.C. (Camb. M.R.C.S. and L.R.C.P., Lond. who is Resident Physician and Pathologist to the College, and Surgeon Captain ('R' Stevens, M.D., Lond. F.R.C.S., Eng. L.R.C.P., Lond. who is Resident Surgeon at the Eden Hospital for women and children. He is the son of an old Civilian and is one of our distinguished Anglo Indians. The Calcutta Medical College and Hospital can therefore boast of a most excellent staff of junior officers.

HIGH MORTALITY IN MADRAS

The mortality returns for Madras, show that the mortality in Madras last week was even greater than was the week before. The number of deaths have reached the still more appalling total of 592, as against 575 of the previous week, and the rate rose from 68 to 67.9 per mille per annum in 1890, when the unsanitary condition of Madras excited so much agitation. The total number of deaths for the two corresponding weeks were 408 and 438, respectively.

THE SEALDAH HOSPITAL.

The new female ward attached to the Campbell Hospital is now nearly completed and will probably be opened in November. The ward is over 300 feet in length and 50 in breadth, and it is capable of accommodating 150 patients. It supplies a want which has been sorely felt for many years, and will tend to keep the main building less congested than at the present moment, when it is made to accommodate hundreds of patients more than it was originally estimated to hold. It is owing mainly to the exertions of the present Deputy Super-

tendent, Mr. Cecil M'Nair, who, despite shortly, that this hospital has been so well looked after. He will be greatly missed on his retirement.

SHORT ITEMS AND PERSONALITIES.

Mr. A. A. Boon who has taken the Degree of Bachelor of Science of the university of Edinburgh is an Anglo-Indian and a son of the late Military Assistant-Surgeon H. Boon, and a brother of the late Surgeon-Captain P. H. W. Boon, I.M.D. He received his early training at Bishop Corrie's Grammar School and was a distinguished pupil of that well known institution during the regime of the Rev. A. W. Atkinson, M.A.

Miss Margaret Goddes, who has had the distinction of being the first woman upon whom the degree of M.D. was conferred by Edinburgh University, followed up the receipt of this honour by marriage. Two or three hours after the brilliant young lady had been "capped" in McEwan Hall by Sir William Muir, she was taking the principal part in the wedding ceremony at Free St. Andrew's Church, Edinburgh. The bridegroom was Mr. Douglas Chalmers Watson, M.H.

"Surgeon.—" I.M.S., writes to the *Englishman* as follows:— "If Reuter is right, as I am afraid he is, in stating that men of the I. M. S. are to get the new titles, please give us the credit of at least not having asked for them. Our fault has been that we did not protest against them. The people at home seem to think that the I. M. S., is the same as the (late) A. M. Staff, which it is not."

The services of Surgeon-Captain C. R. M. Green, Officiating Civil Surgeon of Howrah, have been placed temporarily at the disposal of the Chairman of the Corporation of Calcutta. Surgeon-Captain E. H. Brown, Civil Surgeon of Purnea, officiates at Howrah; Dr. J. A. Fink, Officiating Civil Medical Officer of Bhagalpore, going to Purnea.

Miss L. E. Sykes, M.D., who is in charge of the Lady Dufferin Hospital at Lucknow, appears, by the skilful treatment of the cases under her care, to have made herself generally popular among the native community there. The *Akhbar-i-Ajmal*, a leading Mahomedan paper published in Urdu, at Lucknow, writes in the highest terms of the skill and attention with which she treats the sick.

Surgeon-General Churchill, Officiating Principal Medical Officer, Bengal Command, proceeds home on three months' leave. Colonel Prince, R.A.M.C., officiates. It is believed that Colonel Catherwood, now in England is likely to get the permanent appointment.

The Sanitary Commissioner, Bombay, has applied for the sanction of Government to depute Surgeon-Captain E. C. L. Arun, Deputy Sanitary Commissioner, Sind District, Mysore, for the purpose of acquainting himself practically with the methods of preparing inoculated lymph for vaccination.

It has been decided to hold a big Indian Medical Service dinner at the Chalet, Simla, on the 19th instant, on which date the new Warrant should arrive. The Officiating Director General will preside. The names of intending participants are to be sent to Surgeon-Major Duncan.

Surgeon Captain E. Harold Brown, I.M.S., one of our distinguished Anglo Indians—V.D., L.R.C.P., and S. Edin. L.M.S. (Bombay) has been appointed to temporarily fill the coveted civil surgeoncy of Howrah.

Surgeon-General Cleghorn, Director-General, Indian Medical Service, will not return to India. Surgeon-General Harvey, who is acting, will probably be confirmed as his successor.

The following officers came to Calcutta for the purpose of undergoing a course of operative surgery at the Medical College:—Captain V. McDonald, R.A.M.C., Lucknow, and Captain W. J. Trotter, B.A.M.C., Sittapur.

The Secretary of State has confirmed the decision of the Government of India that officers of the Indian Medical Service holding appointments outside the cadre of that Service, shall be seconded when such employment lasts for more than a year.

The Royal Warrant granting Military rank to the members of the Indian Medical Service, together with a despatch explaining the reason for not forming the service into a corps should reach India by the mail due in Bombay on the 17th instant.

Surgeon-Captain Fullerton, I. M. S., Bengal, acts temporarily as Personal Assistant to the Principal Medical Officer, Bengal Command, *vice* Surgeon-Captain French, who vacates on promotion to Surgeon-Major.

A district Court Martial held at Mian Meer finds First Class Assistant Surgeon Clement Bower Boodrie, Indian Subordinate Medical Department, guilty of drunkenness when on duty. The accused is reduced to the second class.

Surgeon-Captain J. C. S. Vaughan, Deputy Sanitary Commissioner, Western Bengal Circle, has been appointed to act as Civil Surgeon of Burdwan, during the absence, on leave of Brigade-Surgeon-Lieutenant-Colonel W. H. Gregg.

The question of reopening the Cantonment Lock Hospitals is, it is believed, at present under the consideration of the Principal Medical Officer, Her Majesty's Forces in India.

Assistant Surgeon I. T. Mitra has been transferred from Mayo Hospital, Jypore, to the permanent Civil Medical charge of Beawar Dispensary, Rajputana.

Surgeon Colonel Kalipada Gupta, Bengal, has been offered an appointment as Chief Medical Officer by the Nepal Durbar.

Dr. Hayes having resigned the appointment of Planters' Doctor to the Maran District, the Medical Committee have have resolved to advertise for a successor.

The 4th Session of the Congress for the study of Tuberculosis in men and animals met at Paris on the 27th July 1898, under the Presidency of Professor NOCARD of Alfort.

Dr. LAWREN has reported to the Nizam's Government that the outbreak of plague in Sholapore is serious.

Dr. Bhagat Ram Sawhney, M. B. &c., &c., has been appointed Chief Medical Officer, Jammu.

Furlough on medical certificate for five months is granted to Surgeon-Major G. H. Fink, I. M. S.

There are three Anglo-Indians among the London successes for the I. M. S.

Members of the Indian Medical Association who have not yet received their membership certificates are requested to apply for them at once to the Secretary.

Members of the Indian Medical Association who have not received a copy of the Third Annual Report of the Association, or previous Reports, are requested to apply for them at once to the Secretary.

Members of the Indian Medical Association whose subscriptions are in arrears are requested to forward their dues to the Treasurer without delay.

On and after the 1st October, all communications for the Indian Medical Record whether for the Editor, Proprietor or Manager, should be addressed to 36, Park Street, Calcutta.

THE RESPONSIBILITY OF MEDICAL EXPERTS. THE CASE OF DR. MELOCHN BY DR. PAUL REILLM.*

THE case of Dr. MELOCHN is of such an interesting, not to say sensational character, and has attracted such universal attention, that we think the following admirable and full account of it by Dr. PAUL REILLM cannot but be of interest to most of our readers. It comes at an opportune time when public attention has been more than usually attracted to the medico-legal aspect of medicine, and it bears upon some of the most important and difficult questions which may at any moment confront the practitioner, regarding the duties and responsibilities of Medical Service in the cause of Justice.

Dr. REILLM's article runs as follows: In the year 1875, Professor LORAIN wrote thus to a Medical Expert who had sought his advice, "I think that Justice, in its no doubt legitimate zeal attaches too much importance to our reports, and lays upon us too large a share of the responsibility. We should be careful not to merit the charge of excessive zeal to which we may sometimes exposed."

As for the value which the general public and those who instruct it through the Press, set upon our opinions, we would be wise not to attach too much importance if we value our own comfort."

The following are the circumstances which led to the above expression of opinion.

A certain Dr. D—was ordered by a Justice of the Peace to make an examination of a woman who was accused of infanticide. He summed up his conclusions thus.

1. The uterus of the accused B—appears to have undergone a considerable enlargement through the development in its cavity of some product which may have been a pathological tumor, but which was more probably a fetus.
2. This "product" must have been expelled, and if a fetus, probably before full term.
3. It is impossible to fix the exact date of this expulsion, three weeks at least must have elapsed and probably much longer.

Two days afterwards the body of the infant was found, and Dr. A—who on the occasion examined the woman and made a *post-mortem* examination of the fetus, stated in his report that she must have been delivered within one month.

The President of the Court of Assize thereupon reflected severely on Dr. D—finding it strange that he could only fix a *probable date*, while his colleague fixed the *exact date*.

The result of this uncalled for censure was that the Press indulged in an attack on Dr. D—into the details of which we need not enter.

The President of the Court exceeded his rights; in questioning the report of our confrère he appeared to cast doubts on his ability and professional honesty; he doubtless thought his carefully worded opinion too favourable to the accused, and in finding fault with it he went very near accusing him of neglecting his duty, and avoiding his due share of responsibility.

This case stands alone; but for some years past medical jurists, like other medical men have found themselves regarded with suspicion by the public and they have seen their reports however impartial, attacked and disputed.

This is a matter of small moment and as LORAIN advises, too much importance should not be attached to it, it is however more serious to find publicity given to dissensions between medical men, which have lately arisen over matters of expert opinion?

As DECHAMBERN says, the Medical Confraternity should be united by a profound sense of the nobleness of the Art which they exercise in common, and by respect for their mutual dignity.

Up to 1897 the question of the responsibility of the expert had never been raised except in the Press, and matters of this description had never come before the judicial bench. It was under the following circumstances that such tribunals were called upon to express an opinion upon these questions, which possess the highest interest for the whole medical profession.

* Translated from the "Annales D'Hygiène Publique et de Médecine Légale" July, 1898.

On the 18th March 1896, Dr. MELOCHÉ, formerly "interne" of the Nantes Hospital, and physician at Saint-Nasaire was commissioned by the *Juge d'Instruction* to examine a widow named BILLY, who was believed to have aborted.

The doctor examined the accused, but as he had not the instruments necessary for a complete examination, especially neither speculum nor stethoscope, he beforehand informed the magistrate that it would be necessary for him to repeat the examination the following morning.

As Dr. MELOCHÉ was about to examine the woman, she informed him that, on the 15th March, a quantity of blood and clots had come away, but that she had seen nothing that resembled a child. She further pretended that the catamenia had always been regular, and that she had not been pregnant.

Dr. MELOCHÉ was about to leave the Magistrate's room when the latter summoned him to state if the result of his observations afforded a strong presumption of recent accouchement. Placed at a disadvantage by the question, he replied, that he thought that the woman he had examined had been recently delivered.

This reply was immediately entered in the proceedings and an order of imprisonment was executed against the widow BILLY.

Two days later the expert made a fresh examination. In the interval the woman had had some hemorrhage and he was able to state in his report that the neck of the uterus and the walls of the vagina were slightly blood stained.

Auscultation and palpation of the abdomen revealed neither the sounds of the heart, the movements of the fetus, nor ballottement.

As the result of these two examinations Dr. MELOCHÉ drew up the following report which was consigned to the Record Office of the Tribunal of Saint-Nasaire, the 1st April, 1896.

I the undersigned doctor in medicine of the Faculté of Paris, commissioned by M. J. JULES BATILLAT, Magistrate of the Court of first instance of Saint-Nasaire, in accordance with an order dated 18th March 1896, proceeded to Campton the same day in connection with an infanticide, which had been committed there by a widow named BILLY.

This woman was suspected by her neighbours of having aborted secretly on the 15th March. All the witnesses, examined on the 18th March, stated that this woman had been perceptibly large with child, but that since the 15th March her abdomen had decreased in size in a marked manner.

The woman did not deny that the size of the abdomen had diminished, but she attributed this to a large quantity of blood with clots which she had lost on the 15th March, the amount of blood was sufficient to saturate two chemises and the petticoats in which she had slept. She stated that there was nothing that resembled a child, or at least that she saw nothing, I then proceeded to examine the woman and found as follows:

The widow BILLY has had four children, the youngest is four years old and has been weaned 23 months.

She declared that the catamenia had been regular, but less marked for the last few months. Last Sunday she had severe hemorrhage and passed clots. The breasts are full and firm, the nipples are brown and the areolar glands prominent, on pressure the breasts yield a few drops of white milk similar to what is secreted a few days after delivery. The linea alba is of a brownish colour from the pubis to the umbilicus. The abdomen is slightly globular, but at the sides the walls are flabby and relaxed.

Below the umbilicus on each side of the abdomen there are numerous characteristic lines of a pale violet colour, they are of recent date and indicate that the abdomen has recently been considerably distended, and that this distension has recently disappeared.

By careful palpation of the abdomen, which is flabby, but voluminous, the body of the uterus can only be distinguished with difficulty; by vaginal touch combined with abdominal palpation the fundus is felt to be a little below the umbilicus.

By vaginal examination the neck of the uterus is found large and fairly soft, the external os large and the internal fairly well closed. There are multiple lacerations to the right of the cervix and a large tear to the left. These lacerations are old.

The anterior lip presents some granulations.

A little blood is still coming from the uterus.

At my second examination on Friday the 30th March, the symptoms were almost the same; milk in the breasts, numerous characteristic violet coloured lines on lower part of abdomen, fundus below the umbilicus, and finally the woman, from Wednesday to Friday had continued to lose blood. Moreover the cervix and the vagina are blood stained.

To sum up, in this case five things were apparent: milk in the breasts; violet colored lines of recent date on the lower part of the abdomen which pointed to a decrease in the size of the abdomen; a diminution which besides had been observed by everyone and which the woman did not deny. The flabby condition of the abdominal walls and the abundant hemorrhage with clots on the 15th March, which was admitted by the accused: finally the presence of the fundus below the umbilicus and the difficulty of distinguishing the uterus in the abdominal cavity.

These symptoms which in a primipara would have had a different value, were yet sufficient to attract particular attention to this woman. They did not justify a formal declaration that she had been recently delivered, but they formed a strong presumption in favor of this view and showed the necessity of following up the course of these symptoms, to see if the milk disappeared, if the uterus underwent normal contraction. The abundant hemorrhage and the violet colored lines on the abdomen were especially important.

On the other hand neither auscultation nor palpation of the abdomen, nor vaginal examination, had shown any signs of the heart sounds or of active movements on the part of the fetus, nor ballottement.

Besides if the infant had moved, the widow, who had previously borne four children, would have made known the fact which would immediately have acquitted her of having made away with it.

I intended to visit the widow again to see if any change had taken place in the symptoms mentioned above, when I was informed that she had given birth to a child on the 23rd March 1896, at 6 A.M., the infant was in about the fifth month of gestation and lived for half an hour.

Was this a case of twin pregnancy, with delivery of the first child eight days previously, which would explain the hemorrhage of the 15th March, the diminution of the abdomen and the characteristic lines? I cannot say.

Conclusions: (1) The widow BILLY at my two examinations had the walls of the abdomen flabby and relaxed, milk in the breasts, numerous recent violet colored lines on the lower part of the abdomen. She had had severe hemorrhage with clots on Sunday the 15th March. Finally the fundus which was felt with difficulty was below the umbilicus.

(2). All these symptoms combined formed a strong presumption in favour of recent accouchement, without however, warranting a formal declaration to that effect.

(3). They made several other examinations of the woman necessary to ascertain if she had actually been delivered.

(4). Neither heart sounds, nor movements of the fetus nor ballottement could be discovered.

(5). The absence of recent laceration of the cervix or of the fourchette were no proof that delivery had not taken place, for a woman who already had four children, and whose cervix was freely open and lacerated in several places, whose vagina also was dilated and capable of extensive dilatation, could readily be delivered without any fresh lacerations taking place.

(6). The sexual parts presented no trace of violence

Saint Nasaire, the 1st April 1896.

Ed. Dr. MELOCHÉ.

On the 23rd of March, the accused while in prison was delivered of a five month's fetus or what appeared to be a five months fetus, for it was not measured and there was no autopsy; it lived for some hours.

The widow BILLY was at once liberated and she then proceeded against Dr. MELOCHÉ, the result of whose first examination had caused her to be imprisoned.

Such are the facts which led to a most important result. The magistrate contrary to all precedent summoned Dr. MELOCHÉ to tell him the result of his first examination of the accused.

The Magistrate and the doctor were equally wrong. The magistrate should never have entered the simple opinion of the doctor in an official report while the doctor should not have expressed the opinion, until he was convinced that there were sufficient grounds for it, especially when he considered a second examination necessary. Further the Medical

jurist according to the terms of his commission is not required to make an oral deposition before the magistrate, it is his duty to submit a report prepared after careful reflection in the light of his own study, and this alone can be considered official.

Professor BROUARDEL, discussing such premature questions on the part of the magistrate says:—

"You will often be questioned by a magistrate and asked to give your opinion before your investigation is finished, say nothing definite. An answer given under such conditions will influence the future proceedings and the interpretation put upon your final report, it handicaps justice and does not reflect well upon the expert.

Considered in this way it is so difficult to fix responsibility upon the expert that the counsel for the plaintiff M. BRUNSCHWIG addressed a letter to Professor BROUARDEL from which he quotes the following extract in his work entitled '*Responsabilité médicale*.'"

May I ask and can you tell me if any responsibility rests upon the doctor? Or if on the contrary he enjoys the same immunity as a magistrate who orders a person to be arrested on insufficient grounds? In other words must the medical jurist be looked upon as forming as it were a part of the tribunal while he is performing the duties that have been entrusted to him?

On the other hand is he responsible for his mistakes, if they are due to gross error or to negligence, to an amount of carelessness amounting to unpardonable ignorance?

The answer to all these questions is easy. According to article 28 of the Act of 30th November, 1892, on the practice of medicine, "Every doctor of medicine is bound to comply with the orders of a magistrate on pain of fine of 25 to 100 francs." This point had been already decided, in this sense, by the Court of Appeal two years before the law was promulgated.

No doctor is permitted on any grounds whatever to excuse himself or say that he is incompetent. Such is the law.

In an article which appeared recently in the *Gazette des Hôpitaux* this question was discussed and the writer said "It is always easy for a doctor to decline expert work on account of relative incompetence, not being accustomed to make autopsies, or the want of special study"

This is true enough in principle, but in practice it becomes a delicate matter. There is a difficulty in advising a medical man who is established in practice with a large number of patients, thus to confess to incompetence. If the declaration was a private one, he could make it; in a large town he might seek to excuse himself, but if he practices in a small provincial town reports and exaggerations will get about.

The public will not trouble to notice that the doctor declares himself incompetent only as far as medical jurisprudence is concerned, or in the conducting of autopsies, or in some other branch of medico-legal work, one thing only will be grasped and passed from mouth to mouth, viz, that Dr X, when called upon by the magistrate declined because he considered himself incapable of doing what was required of him.

Unfortunately the public and even the magistrates imagine very wrongly, that the title of doctor given to the student at the conclusion of his studies, implies a certificate of general competence upon every point, near or remote, connected with medicine. Nothing could be more erroneous. In spite of the large number of examinations he has to pass, a doctor, and this applies to the great majority, will very probably during the whole of his student's career, never see a case of poisoning by carbonic acid gas or by arsenic; and more likely still will never have performed an autopsy upon a person who has been drowned or hung, nevertheless he is able to pass his final examination brilliantly and to describe the organic lesions which occur in such cases, his knowledge however is purely theoretical and in medical jurisprudence there is a wide gap between theoretical and practical knowledge.

No matter what position he holds, a medical man who confesses to incompetence upon any point will be suspected by his patients of being equally incompetent upon others to which he does not confess; they will conclude that they have placed the care of their health in bad hands, and will specially leave a doctor who has declared himself incapable of deciding whether a person who drowned himself has been drowned accidentally or has been assassinated. Doctors

themselves are perfectly well aware that it is possible to be ignorant upon these special points and to be a very distinguished clinician, unfortunately the public does not see things in the same light.

The same journal adds, "If the magistrate insists the doctor must comply," but a medico-legal report made under such conditions stating the limited competence of the expert, and expressing opinions which are vague and without precision, will place so many arguments in the hands of the defence, and will be of so little use in the interests of justice, that it will not be employed at all."

This point also we are unable to accept. The medical jurist is bound to state in his report, the lessons that he has found and the conclusions he has formed from them. He is obliged to answer precise questions "Has the patient been recently delivered? Yes, or no?"

If the facts observed are of such a nature as not to justify a precise affirmative, if he is in doubt he will reply in a guarded manner, he will say, like Dr. MACDONALD who affirmed nothing, that there are certain presumptions, but he ought never knowingly to make a report in which the conclusions are vague and wanting in precision, for if he does he will take an erroneous view of the duty that has been confided to him, he will favour the defence to the prejudice of the prosecution, while he ought to be perfectly impartial.

Besides if the case comes before the Court, the President when he receives the depositions of the expert, as a witness, (*comme témoin*) will put questions to him and will not fail to ask him about the points which are vague, and will force him to complete the details of his report in public.

Such an examination is very disagreeable to the expert and especially to those who not being accustomed to assist at judicial proceedings are somewhat nervous, knowing that their answers will be faithfully taken down and subsequently commented upon in a report, the Medical Jurist only writes what has been carefully considered; but under cross-examination if he is not in possession of all his senses he may be drawn a little too far, and may in his explanations reveal his private opinion as to the guilt or innocence of the accused.

In fine, once a doctor is bound to co-operate with the law, no matter what the case is and in spite of his pleading incompetence, he can no longer be held responsible on this subject. Professor BROUARDEL says, (*La Responsabilité médicale*).

"The Medical Jurist is only called upon when the Magistrate is unable to decide some technical point. He is selected by the magistrate and it is to him that he makes his report. It is the magistrate who gauges the value of his conclusions, who accepts or questions them. He has chosen the expert but he is not forced to accept his opinions, if he does accept them he is responsible for the consequences, if any one is responsible, it is, therefore, the magistrate himself. It must not be forgotten that the doctor has no option, he cannot refuse the summons of the law, he must comply under article 28 of the Act of 1892. He cannot excuse himself; he cannot urge the plea of incompetence, if then he commits an error who is responsible? Surely it is the person who has selected him, why was he selected unless because he was well qualified? I admit, be it understood, that if the expert culpably by fraud or malice has tried to deceive the court he must be considered guilty in the same way as one who gives a false certificate, or who gives false witness but this does not apply in this case, here the expert does not deceive, he is deceived.

This case came before the civil tribunal of Saint NAZAIRE which at the sitting held on the 26th February, 1897, upon the arguments of M. M. BRUNSCHWIG and GAUTHIER both of the Nantes bar, pronounced the following judgement.

Whereas the action concerning responsibility instituted by the widow BILLY against Dr. X—rests upon the provisions of articles 1882 and 1883 of the Code of the Civil Code.

The elements of the offence, or supposed offence as provided for in these articles are:—

1. An error, negligence or imprudence on the part of the defendant.

(2) A consequence of such error, negligence or imprudence which entitles the plaintiff to damages.

And since no article or provision of the Act of 30th November 1892 modifies, as far as doctors are concerned, the principles of responsibility laid down in these articles.

There are therefore reasonable grounds to inquire if there

was any—(1) Error, imprudence, or negligence on the part of the defendant.

(2) Injury caused by the defendant.

(3) Connection between the error and the injury.

Whereas the injury for which reparation is demanded by the widow BILLY might result—

(1) From her arrest and detention.

(2) From the violent means employed by the medical expert in his efforts to discover the truth.

The second heading may however be struck out since the employment of the speculum is neither admitted nor proved, nor is it stated that it was the employment of this instrument which brought on labour.

But with reference to this second heading, since the arrest is legally proved and there can be no question that the consequences entitle the widow to damages.

Still concerning the third element, the connection between the error and the injury, it is established by the magisterial proceedings that the medical expert was summoned to decide upon a matter of fact, whether his investigations showed a strong presumption of recent accouchement, and that upon his answer in the affirmative an order for imprisonment was executed against the widow.

Thus, therefore, the sole legal point at issue is the error, or rather the negligence or imprudence of the expert, for he was legally ordered to examine the woman to find out if she had been recently delivered.

Considering that the rules of science, even if they are not infallible, are still sufficiently exact to enable the physician in the large majority of cases to arrive at the truth without difficulty, it follows that it is his duty to adhere strictly to them for it is the unanimous verdict of authors who have treated of this branch of medicine that no single sign of accouchement taken by itself nor even a group of isolated symptoms is sufficient to establish a certainty.

When the problem is so difficult that he is unable to solve it, if he does not follow all the rules laid down for his guidance he is guilty of neglecting his duty, more especially in a case of this importance.

Considering further, cases of infanticide are those in which medical experts are most frequently called upon to express an opinion, that all the means of arriving at the proof of delivery are mentioned, and are laid down in special works which are unanimous as to the means, the authors only differing as to the value to be attached to each sign or symptom, consequently ignorance on the part of an expert is inexcusable.

Granted that he did not neglect to inquire into the external circumstances which could guide him in his researches.

But these circumstances should not have prevented him from employing all the resources of science the application of which was the very object of his mission.

That, he should have attached the less value to the declarations of the accused, since he knew that she was interested in disguising the truth and deceiving the law even though her methods of defense, often badly chosen, should run counter to her interests.

Considering that, the cases in which the doctor after following carefully all the instructions laid down by the best authorities still makes a mistake, are exceptional, the proportion of such cases being very small in comparison to the number of accouchements, the mistake that was made necessarily presupposes an error, negligence, or imprudence on the part of the expert.

That, therefore, the expert incurs the necessity of proving that he has not neglected any of the methods which he should have employed.

Whereas the date on which Dr. MELOCH's report was handed in, was subsequent to the accouchement of the widow BILLY, the court should hesitate to accept the statements contained therein.

If however, taking into consideration the fact that the expert was on his oath, and his universally admitted high reputation, the statement contained in his report be accepted as exact and straightforward, it is still necessary to remark that this document consists of three parts.

That in the first the expert relates the symptoms, observed by him on the 18th March.

In the second speaking of the visit of the 20th March, he says, he observed the same symptoms as in his first examination, and adds that neither auscultation, abdominal palpation, nor vaginal examination, gave any signs of the heart

signs, of accouchement on the part of the fetus nor of ballotement.

In the third he gives the conclusions founded upon the results of the two examinations.

It was the medical examination of the 18th March which led the expert to affirm to the magistrate, the probability of accouchement which statement caused the arrest, and appears from the order followed in the report, that it was only at the second visit that he sought for the signs of pregnancy noted above, and remarked their absence.

This suspicion becomes almost a certainty if we consider the report of the official inquiry, for there the magistrate states that the doctor told him that he had not the necessary instruments with him, and that it would be necessary to make a more complete examination of the accused at Saint Nazaire.

Considering that, if it was necessary to make use of a stethoscope to hear the heart sounds, it was, on the other hand, unnecessary to use any instrument to prove the existence of ballotement.

That on this count therefore, there was negligence on the part of the expert, who in the first part of his report mentions the vaginal examination only with reference to the conditions of the neck of the uterus.

Considering that the want of instruments, about which nothing is said in the report, and for which no reason is given in the official report, is another proof of negligence on the part of the expert.

Considering that it is granted, that he was satisfied to affirm the probability of accouchement upon the following symptoms: Milk in the breasts, recent violet coloured lines on the lower part of the abdomen, the flabby and relaxed state of the abdominal walls and the position of the fundus below the umbilicus.

To which he added the profuse hemorrhage with clots noticed by the accused on the 18th March, whereas these symptoms are not the most reliable in a woman who has previously borne children.

It was a grave imprudence on the part of an expert to affirm the probability of accouchement upon indications which he himself apparently did not consider conclusive, for he mentions in addition in his report that there were no recent lacerations of the cervix and lays special stress upon a profuse hemorrhage of which he had no evidence except the statement of the accused.

Far from opposing the presumption of negligence, implied by the rarity of the cases in which experts have been deceived in this manner it is submitted that the documents before the Court confirm it.

And that accordingly the defendant is responsible for the arrest.

Further with regard to the examinations made on the 18th and 20th March, the expert neglected to submit the blood to a chemical analysis, while its composition, is according to all authors who have devoted themselves to legal medicine, one of the most certain indications of accouchement.

Whereas the expert not having been present at the birth of the infant of the widow BILLY, the Court cannot accept as proved his explanation of the absence of ballotement.

Finally it is not established that the expert informed the magistrate of the result of his later investigations, or gave any fresh advice, previous to the date of his report.

That consequently he remains responsible, not only for the arrest, but for the detention up to the time of accouchement.

Whereas, the denial of being pregnant cannot be considered a misdemeanor on the part of the widow BILLY, who was obliged to defend herself, yet this false declaration while not relieving the expert from the complete fulfilment of his duty must be held to somewhat diminish his responsibility.

As still further extenuating causes must be considered, the doubtful morality of the plaintiff the suspicions which rested upon her, and the number of unfavorable reports against herself and her family.

Whereas, in as far as the question of prejudice arises, it is necessary to take into account, the arrest of the widow, the period of her detention, and of the fact that she was delivered in prison.

Yet it must be remembered, on the other hand, that she did not suffer from any of these things after her release.

That in conclusion the Court has in its possession all the facts necessary to assess the amount of damages.

For these reasons, Dr. MELOCH was condemned to pay to the plaintiff the sum of 1,000 francs, and to pay costs.

(To be Continued.)

VITAL STATISTICS OF CALCUTTA.

Statement of Deaths from Principal Diseases in Calcutta during the week ending 13th August to the 10th September, 1893

Week ending.	Cholera.	PLAGUE.				Small-pox.	Fever.	Bowel complaints.	All other diseases.	Total.	Total population, according to the census of 1891.	Ratio per 1,000 of population per annum.

Current Medical Literature.

MEDICINE.

Recent Views on Dyspepsia.

Its nervous form excepted, VERHAEGEN maintains that in place of being a merely functional disease, dyspepsia is always the result of subacute or chronic gastritis, of which he recognises four forms:—(1) chronic simple gastritis or gastric catarrh, if prolonged, terminates in atrophy of the glands and sclerosed connective tissue, and the muscular coat may become involved and disorganised, while the gastric contents show deficient acidity, delayed digestion and abnormal fermentations. Bitters, such as calumba, condurango, quinine or nuxvomica, may be given 15 to 30 minutes before meals till the appetite returns (not a day longer); but drugs have singularly lost their importance and the treatment chiefly consists in regulating the diet according to the idiosyncrasies of each patient and giving small meals at long intervals between each. Milk is the most suitable food and water the best drink. Broth, meat solutions and extracts, peptones, eggs, biscuit, calf's brain and pancreas, poultry, finely hashed meat, beefsteak and vegetables (such as carrots, cauliflowers, spinach, &c.) which contain but few fibres of cellulose are allowable and are a little coffee or effervescent mineral waters in moderation, but pork and stimulants or stimulating beverages are interdicted.

(2) In *Gastritis with hyperchlorhydria* the principal symptom is pain (sometimes severe) radiating from the epigastrium through the last intercostal spaces and the stomach is sensitive to pressure in the pyloric region. Beginning 2, 3, or 4, hours after a meal the pain lasts from a few minutes to several hours, but may be temporarily relieved by the ingestion of food and still more by bicarbonate of soda. Rest in bed, with warm applications, is advised. Diet should be milk and eggs till amelioration when a little hashed meat or bread may be given. Small doses of soda, every 30 to 60 minutes until the end of digestion are useful.

(3) In *Gastritis with hypersecretion* which is a later stage of the preceding or may be looked on as pyloric stenosis, secretion has become constantly continuous in place of intermittent, and during fasting—the stomach which becomes dilated—often enormously, always contains a notable quantity of acid secretion. Lavage with solution of bicarbonate of soda and avoidance of starchy foods, afford the best lines of treatment, but in the advanced forms gastro-enterostomy is indicated.

(4) *Nervous dyspepsia* has manifold manifestations requiring constitutional treatment chiefly directed to the nervous system.—*Lancet*.

Hepatic Cirrhosis.

With regard to the relation of hypertrophic and atrophic cirrhosis, Dr. BARR does not think hyperplasia of round cells and connective tissue sufficient to account

for the increased size in the former which he attributes to engorgement with blood following tricuspid regurgitation due to cardiac asthenia, provoked by over indulgence in strong spirituous liquors, and the atrophic condition, he thinks, is caused by the absence of cardiac asthenia with tricuspid incompetence while diminished functional activity of the liver leads to lessened formation of bile which never deposits gall stones. The earliest symptoms are those of alcoholism while gastric catarrh may precede, accompany or succeed the liver disturbance. BARR lays great stress on dehydration and wasting as a consequence of mechanical obstruction in the liver, wherefore he interdicts alcohol and restricts the fluids ingested so as to lessen the work of the heart. He applies a large sinapism over the epigastrium and liver and treating the gastritis also relieves hepatic and portal engorgements with calomel, but protests against using hydragogue cathartics. As diuretics he employs digitalis with a little nitroglycerine to diminish peripheral resistance. In some cases venesection and the establishment of a collateral circulation may be of use; but paracentesis, if necessary, should be done before the abnormal walls are relaxed: as tapping after the relaxation is usually followed by distressing meteorism.—(*L'pool med chir. journal*.)

Nervous Complications of Influenza.

TWO cases are reported by Dr. FEINBERG (a) 8 days after the onset of influenza a man, aged 38, was seized suddenly with severe pain in nape of neck, upper thorax and right arm which last was paralysed. The pain lasted 4 months; but 8 months later there was paralysis of the muscles supplied by the musculo-spiral and median nerves of the right arm which with the pectoral, trapezius, and sterno-mastoid muscles were greatly wasted and the right eye was shrunken while its palpebral fissure and pupil were smaller than those of the left eye. Electrical reactions were much diminished, but there was no reaction of degeneration. 5 days after onset of his influenza, the other case (b) set. 40, became delirious, lost consciousness and had frequent tonic spasms of the limbs with trismus and rigidity of the neck. Consciousness returned after three days, and a few weeks later the man was quite well except for slight weakness of the right upper limb.—(*Neurol. Centralbl.*)

Treatment of Cholera Infantum by Subcutaneous Injections of Serum.

OF 15 cases of grave cholera infantum in nurslings from 15 to 275 days' old whom REINACH treated with subcutaneous injections of from 10 to 30 c.c., of horse serum, 4 died (3 of concomitant broncho-pneumonia and 1 of follicle enteritis), and in the remainder collapse and cyanosis disappeared while the extremities became warm, the pulse stronger and the temperature raised in 6 to 7 hours after the first injection, and this improvement usually lasted for 24 hours when there was a relapse which permanently yielded to the second injection of serum, and a third dose was seldom necessary.—*Amer Jour of Med. Science*.

SURGERY.**Inherited Syphilis.**

JONATHAN HUTCHINSON, in an article on inherited syphilis, lays stress upon the following points, based upon his own most extensive experience:—That the subjects of taint often group up into healthy men and women. That complete exemption from other indications of taint does not exempt from the risk of an attack of keratitis. That it is not unusual for one child in a family to suffer very definitely, whilst all the others apparently escape. That it is very exceptional for any considerable series of children to suffer in succession from inherited taint. That the mother of one or more syphilitic children may herself remain throughout quite free from symptoms, and apparently in good health. That a condition of general arrest of growth may be one of the consequences of inherited taint. That it is possible for children born within dangerously short periods of the primary disease, in one or both parents, to entirely escape the inheritance. That although, as a rule, after Mercuritis, chorioiditis, etc., the recovery is permanent, there are exceptional cases in which certain progressive changes continue. That it is by no means improbable that some who really inherit taint never, either in infancy or subsequently, show any symptoms. That the children of those who have suffered from inherited syphilis are usually quite healthy. That syphilitic infants may be suckled by their mothers as a rule, without risk to the latter (Mr. HUTCHINSON'S whole experience affords no trustworthy exception to either of these last two propositions).—*Lancet Med. Jour.*

Cocaine in Surgery.

1. The use of cocaine should not be abandoned because its irrational employment has produced deleterious results. 2. Always make a thorough physical examination of the patient before injecting the drug. 3. It should not be used in cases showing organic diseases of the brain, heart, lungs or kidneys, or in persons of neurotic diathesis. 4. Children bear it fully as well as adults. 5. The patient should always be placed in a recumbent position prior to its employment. 6. Constriction should be used whenever possible to limit the action of the drug to a desired area. 7. Use a freshly prepared solution for each case. 8. Distilled water should always be employed, to which phenic, salicylic, or boric acid should be added. 9. A two-per-cent solution has a better effect, and is safer than solutions of greater strength. 10. Never inject a larger quantity than one and one-eighth grains when no constriction is used. 11. About the head, face, and neck, one-third of a grain should never be exceeded. 12. When constriction is possible, the dose may be as large as two grains. 13. Every slight physiological effect is not necessarily to be taken as cause for alarm. 14. Cocaine does have effect upon inflamed tissues. 15. In case alarming symptoms occur, use amyl nitrite, strychnine, digitalis, ether, or ammonia.—*Clinical Medicine.*

Appendicitis.

QUOTING from his 80 cases and noting that the statistics of appendicitis show a much higher mortality after operation than without it, TALAMON who is not systematically hostile to surgical treatment, divides his 80 cases thus:—16 of chronic recurrence; 80, partial fibrous (plastic) and 14 localized suppurating peritonitis; 18, simple parietal appendicitis and 7 diffuse peritonitis; or a larger number of medical than surgical forms of the disease. He thinks it better to try what medicines can do before recourse is had to the knife and to defer operating in cases of intense peritoneal inflammation. If the attack be already diffuse, delay does no harm. If otherwise and generalisation is stimulated by the intensity of the inflammation and consequent nervous reaction, operation may

be altogether avoided, or in 2 or 3 days, when limitation is established there is less risk of changing a local mischief into general peritoneal suppuration as has often been done, in children especially, by premature intervention. Ours is possible in some cases by spontaneous evacuation, but delay entails all the dangers of the perityphilitis and once the diagnosis of local suppurating appendicitis is established the surgeon should step in. The best time to operate is during the comparative quiescence after the out-break and before the fever of suppuration, when limitation is defined and provided no attempt be made to resect the appendix, the risks of the operation are reduced to those of opening an abscess.—*Med. Med.*

Shock After Abdominal Operations.

IN a paper by Dr. A. LAFRANCO SMITH, of Montreal, in the Canada Medical Record, upon "Shock After Abdominal Operations and how to Prevent it," the following conclusions are drawn:—

To sum up: 1. Shock is a powerful irritative of the great sympathetic, causing anæmia of the brain and heart and lowering of temperature.

2. The same results may be obtained by too much blood being lost during an operation, owing to defective hæmostasis.

3. The same results may be obtained by hæmorrhage into the abdominal veins, by the sudden removal of large tumours or quantities of ascitic fluid.

4. Shock is often due to prolonged anæsthesia in a badly ventilated room. Not a moment should be wasted during anæsthesia.

5. Depression of vital powers may also be due to prolonged exposure in wet clothing; the patient should be kept warm and dry.

6. Anæmia of brain can be prevented by operating in Trendelenburg posture; anæmia of heart can be prevented by having the arteries well filled before the operation, and by filling the abdomen with normal salt solution during the operation or by rectal enemas of salt solution after operation.

7. The administration of strychnine in doses of $\frac{1}{10}$ grain for three days before and three days after the operation diminishes danger of shock, partly because it keeps the intestines contracted and thus saves them from being handled; partly because it stimulates even a badly-fed heart to contract.

8. Important organs, such as the uterus or kidney, or even large segments of intestines, can be removed almost without shock provided the operation is performed quickly, with little hæmorrhage, and without much handling or exposure of the intestines.

Surgical Treatment of Ileus.

As a result of his investigations, NAUWYN gives relatively exact rules for the treatment of ileus, as follows:

1. The prognosis of the operative treatment of ileus is most favorable on the first and second day of its existence; on the third day it is markedly worse.

2. The best results (seventy-two per cent. of recoveries) are obtained in those cases in which obstruction is due to a rupture, not including cases of strangulated hernia.

3. In primary peritonitis, this condition and not the resulting ileus, must determine the operation.

4. (a) In chronic intestinal stenosis, the necessity for an immediate operation does not often arise (b) The seat of obstruction can usually be made out exactly if it is located in the duodenum, descending colon, sigmoid flexure, or rectum; otherwise it can only be guessed at. (c) Strangulation can often be diagnosed, and demands an immediate operation.

5. In three classes of ileus an exact diagnosis is possible, (a) Ileus from foreign bodies, e.g., gall-stones; (b) valvulus of the sigmoid flexure; (c) intussusception.

Of treatment other than surgical, NAUWYN says:—

(1) Avoid cathartics. (2) Far better is the employment of large enemata of water, or injections of oil, five to sixteen ounces. Injections of air are less serviceable. (3) Opium should not be given in large doses. (4) Washing out the stomach is advisable whenever there is fecal vomiting or the stomach is overfull. (5) Food and drink should be reduced to the minimum. (6) Passage of distended intestinal coils is of doubtful value.—*Med. News.*

OBSTETRICS AND GYNECOLOGY.

Uterine Tetanus with Threatened Rupture.

BAUNINGS saw a 3-para aged 33, with the following history: On Saturday labour began, and the midwife, an old woman, ruptured the membranes early in the evening. Sunday morning a doctor was called in, and found the uterus firmly contracted and the os nearly dilated. In the evening the condition was unaltered, though pains had been present all day. On Monday afternoon, the doctor endeavoured to deliver, both by forceps and by turning under deep narcosis, but unsuccessfully. On Tuesday at noon BAUNINGS saw the patient; the head had not engaged, but the os was fully dilated. Under narcosis forceps were applied, but no impression could be made; the cervix was greatly thinned out and there was marked contraction of the uterus round the child's neck. The child's heart beats ceased, and as the mother's condition was becoming grave, craniotomy was performed; but still delivery could by no means be effected, and as it was evident that the mother could not live much longer unless labour could be terminated, Cæsarean section was resorted to. The extraction was easy. The uterus was found to be very livid, and its peritoneal covering markedly cedematous, attaining in parts the thickness of the little finger. The operation lasted half an hour, but shortly afterwards the patient succumbed. The child was unusually well developed; the conjugata vera was just under 4 inches, and the transverse diameter at the brim 4½ inches. The uterine tetanus is to be ascribed to the premature perforation of the membranes in a case where a large child was found in conjunction with generally contracted pelvis. It is noteworthy that the child remained alive for so long after the onset of the tonic contraction of the uterus.—*Brit. Med. Jour.*

Value of Antipyrin in Labor.

It is worthy of note that though they can under no circumstances supplant the ordinary anesthetics, the coal-tar derivatives are immensely useful in those forms of pain which may be called nerve lesions, but are practically useless in the pains of inflammatory processes. Thus MISRAOCHI (*Therap. Gaz.*) found antipyrin useless in the pains of perfectly normal labor and in the second stage of labor, but found it most efficient in tedious labor, where the pains were so severe as to reflexly interfere with the proper uterine contractions or where the liquor amni has been discharged too early, and where there is rigidity of the os, as well as for relief of after-pains. When used for arresting threatened miscarriage antipyrin has to be given in large doses as much 30 to 40 grains divided into 2 or 3 doses and given with 30 to 60 minutes interval between.

Dr. WELLS emphasizes the fact that all rises of temperature of whatever nature, following labor, demand immediate attention. If there is a suspicion that the fever is due to septic infection, no matter how slight it may be and this is manifested by the condition of the pulse, local abdominal symptoms, sweats, etc.—the uterus should be thoroughly flushed with copious antiseptic douches, or better still, should be gently curetted with an drill curet. Great care must be taken not to perforate the organ as it is always more or less soft at this time. It is Dr. WELLS's usual custom in the Polyclinic service to follow the curettage with a uterine suppository containing 40 to 60 grains iodoform in cocoa butter, and a slight vaginal pack of sterilised gauze.—*Phil. Poly.*

Puerperal Eclampsia with Special reference to Treatment.

LOOKING upon puerperal eclampsia as a toxæmia peculiar to pregnancy and without parallel except during gestation,

DR. WILLIAM W. FOLTER sums up as follows:—(1) Though its pathogenesis is unsettled it belongs solely to the pregnant or puerperal state, and being neither apoplectic nor epileptic nor hysteric in character depends (2) upon toxæmia due to over-production or under-elimination of toxins (3) originating in (a) the ingesta (b) intestinal putrefaction or (c) fetal metabolism, or (d) in one or all, and (4) there is co-existing sluggishness, improvement or suspension of elimination. (5) When the prodromes of eclampsia appear kidney function and all other symptoms must be carefully watched.

(6) As medical treatment alone is a delusion and a danger to both mother and fetus the treatment should be (a) preventive or (b) curative, that is (a) hygienic or (b) obstetric measures combined with medicinal treatment.

(7) To nourish the patient and dilute and hasten the elimination of the poison give milk-diet and distilled water in the pre-eclamptic state.

As it is liable to induce anaemia blood-letting should be employed only in cases of plethora or cyanosis. (b) Glonoin may be freely given as it diminishes vasomotor spasm; but (10) Veratrum viride which is a cardiac depressant is a dangerous remedy to push.

(11) Eclampsia being the expression of a further maternal intolerance of the fetus the sooner the uterus is emptied of its contents the better, and the prompt induction of labor (even premature) is not only a rational application of science to a desperate condition, but is also the (12) only basis of expectation for a diminished mortality in a toxæmic disease possessing a very high death-rate.—*Jour. Amer. Med. Assoc.*

Treatment of Obesity in women.

OWING to possible interference by peri-uterine adhesences, LUTAUD says that women require a different kind of treatment than that prescribed for men and finding scammony the purgative best adopted to such cases, simultaneously applies medical, dietetic, local and hygienic measures.

He prescribes:—(1) Scammony grs. xv. Ol. anise gtt. i. at midnight and repeated every 2 or 3 nights (2). Immediately before eating of a morning, a wineglass of some alkaline sulphate purgative water or a teaspoonful of ox. Fol. Sennæ, Pot. Tart. Acida, and Sulphur Sublim aa grs. xlv, powdered liliolum grs. xxx and Sacch. Alb. 3x. (3) R. Pot. lod. ʒiiss, Ext. Fuci Vesic ʒi mxxv, and Syrup, Aurantii ʒvi. Sig. ʒss. on the nights when scammony is omitted.

For the dietetic part he orders:

Breakfast, 7 to 9 A.M.—Lean meat ʒii, toast or rolls *ad lib* and coffee without milk.

Lunch, 11 A.M. to 1 P.M.—Meat at discretion, toast or rolls ʒii, one egg, cheese, and a cup of tea.

5 P.M.—Tea or a glass of wine with a cracker.

Dinner, 7 to 8 P.M.—No soup, fish or meat at discretion, salad, vegetable ʒii, cheese, toast or rolls ʒii, a glass of pure Bordeaux or Burgundi.

Supper, 11 P.M. to 1 A.M.—A slice of cold meat, a cracker and a glass of madeira.

The local treatment consists in scientific massage of the uterus and adnexa and of the abdominal and lumbar regions.

Exercise he finds hardest to enforce or regulate but he advises parlour gymnastics and bicycling and the Turkish bath followed by the douche and massage.—*Jour. de Med. de Paris.*

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

Motor and Sensory Channels in the Cord.

THE generally quoted conclusions from experiments are that motor channels cross at the bulb, sensory channels in the cord. Both statements must be qualified, and we may say at once that, whereas precision will be added to the first statement, reservation to the second must be made amounting almost to contradiction. With regard to motor channels, while their major part cross at the discussion of the pyramids, a minor part (in man) cross in the spinal cord, and we shall see that these parts are picked out by degeneration, as well as recognizable by their tardy development as the crossed and direct pyramidal tracts. But with regard to sensory channels, the evidence is far more uncertain and unfinished. Clinical evidence shows that the sensory tract crosses somewhere, but not where, until recently the statement was repeated unchallenged, and by mere force of repetition acquired perhaps undue credit, to the effect that sensory channels cross in the cord. Now however there is an increasing disposition to abandon this view, the recent experiments of GOTOH and HORLEY, and those of MORR, have yielded evidence in opposition. The electrical token of centripetal impulse has been found most pronounced on the same side of the cord as excitation, monkeys after hemisection have been found with the less sensitive leg on the same side as the lesion, as was originally stated by GLEN seventeen hundred years ago, presumably from experiments on monkeys. To such opposition evidence must also be added the indirect testimony of degeneration—ascending degenerations above a hemisection are most marked on the same side of the cord, and degenerations between the bulbar nuclei and the cerebral cortex cross the middle line at the discussion of the fillet. We seem, in fact, to be approaching the conclusion that sensory as well as motor channels have their major discussion in the bulb, their minor discussion in the cord, in which case we must admit that sensory impulses from each side of the body can pass up both sides of the cord, but that most pass on the same side—DR AUGUSTUS WALLER, "An Introduction to Human Physiology" page 481—*N Y Med Rec*

Passage of Substances from Fetus to Mother.

LANNOIS and BRIAN having had under observation a patient with grave symptoms of albuminuria origin, in whose case the symptoms suddenly disappeared on the death of the fetus, though the latter was not expelled till seventeen days later, made some experimental inquiries, from which they conclude, (1) That substances (such as salicylate of soda, iodide of potassium, and methylene blue) injected into the fetus, pass through the placenta, and can be detected in the tissues and urine of the mother (2) This experimental fact supports the view already advocated by LANNOIS, that normal excretory products of the fetus pass through the placenta to be eliminated by the maternal organism (3) In cases of renal insufficiency these waste products of foetal life can therefore in part contribute to the maternal auto-intoxication and consequently can play a part in eclampsia and other accidents associated with the albuminuria of pregnancy—*Brit Med Jour*

Cause of the first Sound of the Heart.

THE closure of the auriculo-ventricular valves and the muscular contraction of the ventricular walls are regarded by many authorities as the source of the first sound, but SIR RICHARD QUAIN points out that this theory is incorrect, as his investigations prove that the first sound is caused by the impact of the blood driven by the action of the muscular

walls against the blood produced by the columns of blood in the pulmonary artery and aorta which press upon the semi-lunar valves.

Difficulties of Defecation in Infants.

WHO strain violently at expulsion of semi-solid faeces afford problems whose solution DR THOMAS CHAS MARTIN thinks is in the solution of the infantile stool and the imperfect development of the parts concerned in the mechanism of defecation which latter are—(1) The infant's lower gut is muscularly deficient and its intrinsic peristaltic power unequal to the tension required for faecal expulsion.

(2) Mobility and angulation of the infant gut conspire to obstruct the passage of formed faeces.

(3) The disproportionate great resistance of the valves in the infant rectum is obstructive.

(4) Owing to the greatly contracted bony pelvic outlet the expansibility of the anus is deficient (or insufficiently) and constitutes an obstinate obstruction to the passage of semi-solid faeces.

(5) The infantile mesentery is too long to hold the upper rectum steady under the applied auxiliary force, while in the infant, who is in reality undergoing formative development, there is not that physiologic descent of the entire pelvic floor which reduces the least possible resistance to the minimum in adult defecation—*Virginia Med. Semi. Monthly*.

Hæmatozoon of Goitre.

A Meeting of the Academy of Sciences was held on July 4th, when M. GRASSET gave an account of his researches among persons afflicted with goitre. Knowing the department of Puy de Dome was that where cases of goitre were the most common he went there, and after studying the question arrived at the following conclusions. Goitre is not a local affection, but a general one, with one predominating symptom—namely, an enlarged thyroid. Just as the enlarged spleen is the predominant symptom in malaria so the enlarged thyroid is the predominant symptom in goitre. There is a curious parallel also between malaria and goitre. Both have a special geographical distribution, both affect mainly a gland having an internal secretion, and in both when they reach an extreme degree cachexia supervenes—in the one case the well-known malarial cachexia and in the other cretinism. M GRASSET examined the blood from eight persons who suffered from recent goitre and was able to demonstrate the presence of a parasite. It showed in the form of spherical segmented bodies, larger in size than a red corpuscle, and recalled the hæmatozoon of malaria—*Lancet*

Protective Power of Leucocytes.

DR JACOB says that if an infectious disease attacks the organism the protecting power of the leucocytes depends upon the amount of the toxin produced by the invading bacteria. If this toxin amount be very great, the white blood corpuscles are affected by a continuous negative chemotaxis, they do not leave the blood making organs and they do not form any bactericidal secretion. Should the amount of bacterial toxin on the other hand, be only moderate, the negative chemotaxis is gradually changed into a positive one, the leucocytes hurry to the seat of conflict and form bactericidal products. These latter, however, are of a generic, not of a specific nature, it is only from the two components—the toxin of the bacteria and the secretion of the leucocytes—that a resultant antitoxin is formed, which antitoxin kills or at least diminishes the power of the bacteria. It is at this time that phagocytosis sometimes occurs, the leucocytes taking upon themselves the role of transporters after having fulfilled that of bactericidal secretors.—*N. Y. Med. Record*.

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Peculiar Adulteration of Bread.

Was detected at Havre where the French Government seized a consignment of 10,000 lbs. of finely ground sawdust which was imported by one M. FRESSAT, who was forthwith arrested and confessed that he had carried on this nefarious trade for some time, during which he had shipped over 5000 wagonloads (i.e., about 268,800,000 lbs.) of this sawdust to various parts of France, where his customers were mostly millers who ground the sawdust in with the wheaten flour they supplied to the bakers. The investigations and resulting prosecutions will involve a large number of millers and bakers in the West of France, where FRESSAT had carried on his operations on an extensive scale to the physical and financial detriment of thousands of bread-eaters.—*Proc. Med. Jour.*

Serum Therapy of Diphtheria.

Rests on a tangible foundation instead of still remaining in the stage of empiricism and Professor KNOWLTON, stated at the last congress of the German Surgical Society, that from 1880 to 1890 before the introduction of serum, his clinic treated 1,386 cases of diphtheria, with the results shown in column A, while since 1894 he had treated every one of the 487 cases that came into hospital with anti-diphtheric serum with the results in column B.

	A.	B.
Total number of diphtheria cases ...	1386	487
Total number of deaths ...	594	55
Percentage of deaths ...	39	12
Cases operated on by tracheotomy &c., ...	662	101
Number of deaths ...	432	36
Percentage of deaths ...	66	35
Number of cases without operation ...	674	336
Number of deaths ...	96	19
Percentage of deaths ...	14	5

Wherefore he concludes there is a decrease in (1) the death-rate and in (2) the number of cases requiring operation as well as in (3) the mortality of the cases operated on. He states improvement begins immediately after the injection which instantly arrests the morbid processes.

Lobster-poisoning simulating Atropine Poisoning.

Dr. FISCHER reports such a case. A man and two women having partaken of lobsters, were seized with severe vomiting of a bilious nature, and soon presented the following symptoms, so characteristic of atropine-poisoning: Dryness of the throat, with difficulty of deglutition; dilatation of the pupils, imperfect accommodation; dry, hot skin; dulness of intellect, and general feebleness. There was also very obstinate constipation, the author having succeeded in inducing an evacuation only after large doses of castor-oil, senna, magnesium sulphate, and several soap-enemata. The general toxic symptoms improved under the hypodermic administration of pilocarpine (1-7 grn.), while for the eye-symptoms it was found necessary to employ eserine (1 to 2 drops of a 5-per-cent. solution, twice daily).—*Cal. Med. Jour.*

Law of Libel and Slander as affecting Physicians in America.

LIBEL consists in printing or writing anything unjustifiably accusing private persons, officials or governments of

anything tending to injure them, make them ridiculous or harm them in reputation or public esteem. Slander is an oral statement similarly made, but an accusation may be slanderous or not according to the vocation of the accused and the practice of the State in which it is uttered. A retired physician may be accused with impunity of what would slander a man in actual practice, and while it is slander to impute professional ignorance or malpractice to a physician, it is not actionable to say, he was at fault in any special case. A physician seeking notoriety by puffing himself cannot recover damages from those who frustrate his attempts. Except it can be proved that there was a mistaken (though *bona fide*) diagnosis or that the article was really useless. It is slander to falsely attribute a contagious disease to any person or condemn any article used in medical practice. A person uttering slander to a second person who repeats it may escape from responsibility if the damages result from the utterance of the second party and not from that of the originator. In any case actual damage must be clearly proved.—*Phil. Poly.*

Tubercular Infection of Rooms.

Dr. RAMSOME, in a communication recently made to the Royal Society, reports the results of his investigations into the influence of products of respiration etc., on the growth of the tubercle bacillus. They prove that organically charged vapours form an excellent culture medium when kept away from the disinfecting influence of air and light. This power of promoting its growth is particularly manifest when the supporting substance is wall paper. Growth may take place at the ordinary temperature of dwelling rooms. There is, therefore, no safety against the increase of the organism in ordinary living rooms in which ordinary tuberculous dust is present, and in which the natural disinfectants of the bacillus, fresh air and light, are not present in sufficient amount to destroy its virulence.—*Treatment.*

Lead in Children's Toys and Buttons.

A NUMBER of children's toys, notably the furnishings for doll's kitchens, have been confiscated by the police-authorities of Berlin, and their further manufacture forbidden, because of the amount of lead they contain. Not more than 10% of lead is allowed to enter into the composition of children's toys in Germany, because of the danger of lead-poisoning. In some cases it was found that the toys contained as high as 80% of the metal. A very high percentage of lead was found also in buttons and other articles for children's wear, and these too were condemned. Lead-poisoning is considered by German health-authorities, too serious an affair to be trifled with, hence the stringent regulations.—*Phil. Med. Jour.*

Infant Feeding.

Dr. L. EMMETT HOLT concludes as follows: 1. That good breast milk is the best infant food. 2. That no substitute for breast milk can be trusted which does not furnish essentially the same elements—fat, sugar, proteids, etc.—as breast milk. 3. That these elements are found only in the milk of other animals, cow's milk being the only one available for general use. 4. That cow's milk requires some modification before it is given to infants.—*N. Y. Med. Rec.*

THERAPEUTICS AND PHARMACOLOGY

Nutrient Enemata.

BRANDENBURG and HUPPKE of Biegel's Clinic draw attention to the value of alcaenose in rectal feeding. They think that nutrient enemata are not so widely employed as they ought to be. At first eggs were used for rectal feeding, and later these were peptonized. Milk has also been much employed. LEUBA's pancreatic meat clyster has not been so widely used owing to difficulties in the preparation. A disadvantage in egg and meat clysters lies in the fact that decomposition may take place, and so lead to irritation of the bowel. According to BRANDENBURG's experiments casein is only slightly absorbed, and the absorption of fat is also small. The increased excretion of urea provides important evidence in regard to the absorption of albumens from the rectum. The amount of nitrogen in the stools is not so reliable, because there may be a long retention in the rectum of the materials used. Investigation into the metabolism has been made in Biegel's clinic with several artificial food stuffs. The authors have used alcaenose, which contains albumens and carbohydrates in a digested state. It is thus a mixture of albumoses and maltose. The urea excretion, the amount of nitrogen in the stools, the presence of ethyl sulphuric acids in the urine, were especially attended to, as well as the general condition of the patient. In the many cases in which alcaenose was used no unpleasant effects were observed. The investigations into metabolism in three cases embraced three periods: (1) A preliminary period with known diet; (2) the alcaenose period; and (3) an after-period. The details are given in tabular form. There was one case of gastric ulcer, one of arterio-sclerosis with hyperacidity, and one of neurasthenia. In all the cases there was a considerable nitrogen excretion in the urine, amounting in some instances to half the amount of nitrogen in the clyster. The same amount was never found when casein was used. There was no increase in the intestinal putrefaction. The authors conclude that alcaenose is especially suited for rectal feeding.—*Brit Med Jour.*

Dangers of Blisters.

HUGHARD, in the discussion following Robin's paper on Bloodletting, Blistering, and Emetics while agreeing with the use of bloodletting and emetics attacked the blister. (1) It often produces an open wound, which facilitates secondary infections or the absorption of cantharides. (2) Besides causing the well known inflammation of the kidneys and bladder it has a general congestive action. (3) Thus even in those diseases where it is most often used, such as pneumonia and pleurisy, it should be discarded, since, though it increases pulmonary ventilation, it increases also pulmonary congestion. (4) It tends to close excretion by the kidneys, so important in all infective diseases, and this is especially harmful in those normally causing albuminuria. Instead of aiding the excretion of toxins blisters are likely to produce a fresh intoxication. (5) The only real use of blisters is in their revulsive and analgesic action. This effect is best obtained by less dangerous means, such as mustard plasters or cold baths.—*Brit. Med. Jour.*

New Treatment of Syphilis.

LALANDE, states that he has obtained remarkable results in the treatment of syphilis by the use of a fluid obtained by macerating young calves' horns, finely powdered in a one-per-cent. saline solution. These horns are especially rich in keratin. The fluid thus obtained is yellow, clear, limpid,

with an odor suggestive of burnt hair, and contains small amounts of calcium and potassium sulphate, calcium phosphate, and large amounts of sodium chloride and gelatin. This liquid is injected subcutaneously in doses of 15 to 45 minims once or twice a week, or even every day according to the urgency of the case. There is a slight reaction at the point of injection which soon disappears. The curative effects generally are manifest as early as the third injection. Mucous patches fade away, cutaneous lesions become copper-colored in a few days and then disappear, while ulcerating lesions dry and their crusts fall away leaving a smooth skin underneath. In this manner there have been treated thirty patients, seventeen of them being women. In nine cases the treatment was begun with the primary lesion, in nineteen in the secondary period, and in two in the tertiary period. The author does not offer any theory to explain the action of remedy, but the results were to him most satisfactory.—*Med. News.*

Correspondence.

FUTURE POSITION AND PROSPECTS OF CIVIL ASSISTANT SURGEONS. ANOTHER SHAM.

To THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I beg to send you the following article from the *Lahore Tribune*:—"The orders of the Government of India, which have just been issued with reference to the improvement of future position and prospects of Civil Assistant Surgeons, will be received with feelings of profound disappointment by the officers concerned. The question was taken up not a day too soon. The position of Civil Assistant Surgeons has remained unchanged for half a century. The service to which they belong was first constituted as a regular Government service in 1843, the year in which the Punjab was annexed. During the past fifty years there has been no increase to the scale of pay which was originally fixed for the three grades of Civil Assistant Surgeons, formerly called Sub-Assistant Surgeons. Now this period has witnessed the re-organisation of other branches of the public service, more especially since the Mutiny. In 1849, the lowest class of subordinate judicial officers—the *Munsiffs*—received a salary of Rs. 100 per mensem; but they have for some years been drawing double that sum. The scale of pay for ministerial officers has also been increased; but the position of Civil Assistant Surgeons in respect of pay now practically remains the same as it was half a century ago. When their official designation was changed from Sub-Assistant Surgeons to that of Assistant Surgeons, they naturally expected that something would be done to improve their position and prospects; but this expectation was not realised. It was revived when the Public Service Commission was appointed a dozen years ago by the Government of Lord Dufferin; but the constitution of the Medical Services in India did not unfortunately, for reasons best known to the authorities, fall within the scope of the inquiries entrusted to the Commission. The Government of India have, however, now discovered that "of recent years the opportunities which are offered to natives of India, educated in medicine, according to European methods, of earning a living by private practice without entering Government service have much increased, and as a consequence the members of the service have come round to be dissatisfied with their prospects." It is a great pity that this discovery was not made earlier. It is notorious that the Civil Assistant Surgeons have long been dissatisfied with their position and prospects. And their dissatisfaction was enhanced by the raising of the status of European and Eurasian Apothecaries, who are decidedly inferior to them in professional qualifications. They have from time to time submitted memorials to Government praying for an increase of pay in the various grades of their service; but as they were natives of the country, their case did not receive favourable consideration.

It must be said to the credit of the Bengal Government that they took up this important question and appointed a Committee on the pay and prospects of Civil Assistant Surgeons. When the Committee made their report, Sir CHARLES MILLIOT, the then Lieutenant-Governor, submitted, in February 1895, definite proposals for effecting improvements in the position of this useful class of pub-

lic servants. On receipt of the recommendations of the Government of Bengal, the Supreme Government decided to devise a scheme for bettering the conditions of service of Civil Assistant Surgeons not only in Bengal, but throughout India. With this object in view, the Government of India invited the opinion of Local Governments and Administrations upon such of the recommendations of the Government of Bengal as had recommended themselves to the Governor-General in Council as likely to be suitable for adoption in all the Provinces. These were:—(a) the abolition of unemployed pay, which is the rate of pay which an Assistant Surgeon receives in certain Provinces while he is supernumerary and without a definite appointment; (b) the creation of a new grade of Civil Assistant Surgeons on Rs. 300 a month; and (c) the reservation of a certain number of civil stations for the medical charge of Civil Assistant Surgeons. In inviting the opinion of Local Governments and Administrations upon these proposals, the Government of India pointed out that under existing orders unemployed pay is given to Assistant Surgeons only, when, having no temporary or permanent charges, they are merely attached to hospitals or on similar duty; that the number on unemployed pay would, if the service were carefully recruited, be very small; and that it would be a necessary condition of the abolition of unemployed pay altogether, except as a punishment, that greater care should be exercised in controlling recruitment. It appears that the Bengal Committee had recommended that an increase of Rs. 50 a month should be granted to Civil Assistant Surgeons at the end of 21 years' service, subject to a professional examination, and that those who were in receipt of this allowance should be graded as Senior Assistant Surgeons. This proposal did not, however, commend itself to the Government of India. Instead of adopting it, they suggested for the consideration of Local Governments and Administrations the following scheme as being more likely to increase the attractiveness of the service:—(1) that the *cadre* of Assistant Surgeons should be put into four grades—on Rs. 100, 150, 200, and 300 a month, respectively, (2) that the pay of Rs. 100 should be drawn continuously from the date of entry into the service; (3) that promotion should be made after seven years' service, subject to the usual examination; (4) that after 14 years' service a second examination should be held for promotion to the grade on Rs. 200, to which only those considered by the Inspector-General of Civil Hospitals to be fit for promotion would be admitted; (5) that promotion from the grade on Rs. 200 to that on Rs. 300 should be made entirely by selection and without any further examination but subject to a minimum of seven years' service in the lower grade; (6) that further advancement to the independent charge of a civil station should depend on exceptional qualifications and ability. The Government of Bengal had proposed that certain civil stations should be specified as charges to be held by Civil Assistant Surgeons. The Government of India did not approve this proposal. They observed that Civil Assistant Surgeons should be entitled to be appointed to the medical charge of a certain number of civil stations, if that could be arranged with due regard to the number of Civil Surgeons reserved for Commissioned Medical Officers and for Military Assistant Surgeons. It will thus be seen that in the matter

to made by the members of the Plague Commission. In this way a number, at any rate, of military service for India would be formed and the recommendations of the Commission put into execution without delay."

THE INDIAN MEDICAL SERVICE.

Dr. FLENNER writes in the *British Medical Journal*:—"Now that your efforts on behalf of the Army Medical Staff have come to such a successful issue, will you kindly bring to notice some of the grievances of the Indian service? There can be no doubt that service is not now regarded as highly as it was twenty-five years ago. This is largely on account of so-called economies, among which may be enumerated excessive reduction of administration and other lucrative appointments; the difficulty of getting leave or furlough except on medical certificate, the cutting down of allowances to the lowest scale, as witnessed in the last campaign incessant transfers and removals, delay in carrying promotions on vacancies. I consider that there is a want of esprit de corps in the Indian service which prevents united effort as in the Army Medical Service. The competition for the Indian Medical Service is gradually falling off, because the conditions of service are not good enough. The remedies may be briefly summarised as follows:

1. The Surgeon-General with the Government of India should be Secretary to Government in the Medical Department.

2. Inspector-generals of civil hospitals should be secretaries in the medical department to their respective local governments.

3. The strength of the service should be materially increased.

4. Officers in civil employ should draw their full pay, instead of having allowances docked under the idea they can be recouped by private fees.

5. Transfers should be much reduced.

6. Officers under the rank of major should draw horse allowance.

7. A general increase of pay should be made.

There are other reforms that might be suggested, but it is a notable fact that during the past twenty years the officers who have found advancement have been those who have advised the cutting down of appointments and allowances."

The *British Medical Journal* thus sums up its correspondent's grievances which seem to hinge upon two points, which may account for a waning popularity of the I.M.S. —

1. Indian medical appointments are no longer sufficiently numerous or lucrative.

2. The establishment is decidedly undermanned."

BOMBAY MEDICAL UNION ON THE BENEFITS OF INOCULATION.

The Bombay Medical Union, after a discussion extending over three or four meetings, passed on the 8th November the following resolution:—"That this meeting is of opinion that, considering the data now available and the satisfactory results of the observations collected regarding the protective effect of Professor HARKIN'S plague prophylactic, the time has arrived for the profession to make a definite pronouncement on the subject and to invite the public to resort freely to protective treatment as the only safeguard against the plague. The immunity derived from inoculation, when done with a full dose, appears to last for at least six months, but there is a possibility of its lasting much longer. From observations collected lately, it appears that a second inoculation, done ten days or so after the first, further reduces the incidence of plague in those who resort to inoculation, and a third, if such be practicable, would increase the

immunity still further. The public are, therefore, to be invited to resort to at least two inoculations, and even to a third if practicable. The duration of the protection is also likely to be enhanced by such a repetition. This meeting of medical men, who have had wide experience of inoculation on persons of all positions, ages, and condition, declares emphatically that the rumours of inoculation originating different diseases are devoid of any foundation; that considering the nature of the prophylactic, which does not contain any living germs, such an eventuality is absolutely impossible; and that there are no facts to show that inoculation aggravates any existing ailments, despite the rare and isolated instances which may at first suggest such an idea." Four native doctors opposed the resolution.

TUBERCULOSIS AND PSEUDO-TUBERCULOSIS.

Bacteriology makes yearly advances on so large a scale that the clinician, surgeon, and practitioner must rely more and more on those who make a speciality of the science, for even the professional pathologist is becoming handicapped. For several years physicians have talked glibly of the bacillus tuberculosis, and apparently on safe grounds, for it seemed as though that microbe had been proved to be a "good species," as zoologists would say, as definite as feline or ilex aquifolia, and with as definite specific habits and properties. Dr. FLENNER, of Baltimore, has recently detected an organism in tuberculous deposits from a man who died with extensive consolidation in both lungs, the symptoms being precisely those characteristic of pulmonary tuberculosis. This germ is figured and described in the July number of the *New York Journal of Experimental Medicine*. It is not simply another species of the genus bacillus, to which *B. tuberculosis* belongs, on the contrary, it is included in a totally different class of micro-organisms, the streptothrices as defined by Kruse. The genus streptothrix includes *S. actinomyces*, associated with a well-known disease, and *S. Madurae*, found in Madura foot. After a careful description of the micro-organism, which he terms *S. pseudo-tuberculosis*, and a full account of the histological changes with which he found it associated, Dr. FLENNER concludes that this species is the cause of the pathological process which he detected and that especially in peritoneal deposits, the pathological picture of this disease, which he terms "pseudo-tuberculosis heminis streptothricis," resembles so nearly tuberculosis in human beings that the two diseases can be separated only by the demonstration of the causative micro-organism in each case; yet Dr. FLENNER thinks that possibly at some future time a clinical picture differing from that of true tuberculosis may come to be established for this disease.

TREATMENT OF PERITONSILLAR ABSCESS.

The following method is advocated by Dr. DUNBAR ROT. As the majority of abscesses follow from tonsillitis, his efforts are always to the abortion of this inflammation, and thus he accomplishes, if at all, by the administration of a good dose of calomel followed by a saline purge. The tonsil and surrounding pillars are painted thoroughly with a sixty-grain solution of nitrate of silver, and this is repeated once daily. He starts early with hot gargles of vinegar and hot water, as hot as can be borne, and then hot fomentations are applied externally. Salol and phenacetine always make the patient feel more comfortable, and for this reason alone he prescribes them.

As to incisions, he has never opened a peritonsillar abscess at any point except above and posteriorly to the tonsil, notwithstanding such eminent authority as he quoted to the contrary. Nor, furthermore, does he make deep incisions with a knife, but simply a small puncture about an eighth of

EXHIBITION AND RESULTS.

It is encouraging to find the *Times of India* filled with as follows of the labors of the Hon. Major Ross, I.M.S.

The account of the researches of Surgeon-Major Ross in the course of an extraordinary test of the malarial plasmodium, read by Dr. FARRER MANNING in the section on tropical diseases of the British Medical Association, and contained in a condensed report of the Edinburgh meeting, is one that cannot fail to interest our readers everywhere. Not only is the subject of malarial one of perennial concern to practitioners in many parts of the United States, but the method pursued by this patient worker, and that by which he achieved such brilliant results, is an example of what a truly scientific investigation should be. Dr. Ross did not confine himself with the observation that there is no malaria in certain districts where mosquitoes do not bite—shrewd guesses based upon such coincidences had been made by MACDONALD and MANSON years before KOCH gravely denounced the theory as his own—but he followed the plasmodium in all its evolutions and its travels through the body of the mosquito. It is true his studies were, for several reasons, made with the plasmodia pathogenic to birds, but the results may fairly be applied to man, and we have as a result the actual demonstration that, in whatever other ways malaria may enter the human body, one way at least is through the proboscis of the Culicidæ.

RAILWAY MEDICAL OFFICERS AND THEIR STATUS.

We notice with much regret and surprise, the omission of Railway Medical Officers as part of the "Graded List of Superior Officers" in the "List" recently published by the various State Railways of the country. The omission may be accidental, as medical officers are subject to frequent transfers, but the bare fact of such omission from the "List of Superior Officers" leads to the natural supposition and the very obvious conclusion, that medical officers on State railways are not superior officers but subordinates. Now as engine drivers, guards and clerks are the only classes excluded from the "List of Superior Officers," the exclusion of medical officers brings them on the same social and official level as these classes, and they therefore cease to command that consideration and respect among railway employees which their professional position deserves. Naturally there is much heartburning among railway medical officers owing to this invidious state of things in regard to their status. We have no desire to make comparisons between the various occupants of the "List of Superior Officers" of State Railways, but we feel that that list can suffer in no way by the admission into its fold of all Railway Medical Officers. They certainly can claim a position there by virtue of their being gazetted officers, and we sincerely trust that attention having been drawn to a very just cause of offence, it will be removed by those in authority on our railway administrations.

THE INDEPENDENT MEDICAL COLLEGE OF CHICAGO IN BOMBAY!

The *Times of India* says:—"We learn from the advertisement columns of a contemporary that it is proposed to hold an examination in Bombay in December next, for the M.D. degree of the "Independent Medical College, Chicago." The gentleman running the show calls himself the secretary of the representative committee, and we learn that the examination is to be held under the supervision of a representative committee appointed by the college authorities. As we have heard a good deal from time to time of bogus American degrees, we should be glad to know more of the gentleman's credentials, and to see the names of the representative committee.

From training colleges at the present time is going in India, and we think it would be better if they contented their wanderings to their own country.

India has already a superabundance of medical graduates and medical diplomas of its own, and they very well do witness the latest exhibition of Yankee catapots.

We trust that this innovation will impress upon the government the absolute necessity of doing something to systematise Medical Education and Medical Degrees in India."

SUPERINTENDENT OF THE MILITARY MEDICAL CADETS OF CALCUTTA.

MAJOR H. O. HODGKINS, I. M. S. the popular and successful Superintendent of the Calcutta Military Medical Cadets, is on the eve of his retirement from the service, and the time has come for appointing his successor. The post is an exceedingly onerous one and is surrounded with many difficulties which call for an exhibition of kindness and firmness, supported by a personal individuality that will command respect. Major HODGKINS has filled his difficult office with marked ability and conspicuous success, so that our European Military Cadets at the Calcutta Medical College now enjoy a reputation for sobriety, industry and integrity such as they were never so largely credited with before. Bowdysm has died out and our young military friends are doing well in both lecture room and hospital work. A serious responsibility rests with the Director-General I. M. S. in nominating Major HODGKINS' successor, and we earnestly hope that no second rate man will be appointed. We need an officer of sound English education, thorough English manners, gentlemanly bearing and one well up in professional work. He should be a strict disciplinarian but not a bully or a martinet. A careless choice may disharmonise the working of the whole class and disorganise the many years of patient labor which Major HODGKINS has spent in building up the reputation of this class.

MEDICINAL CURE OF STERILITY.

MANY a household is rendered unhappy by the absence of children. This is sometimes owing to the husband, and sometimes owing to the wife, but in many cases it is almost impossible to determine the real cause of the trouble. Here JONES, of Edinburgh, counsels not to forget the sedative affinity of belladonna toward the female sexual organs, and gives an opinion that the drug is followed by more or less benefit in very disease to which these parts are liable; and in married women who, though apparently enjoying the best of health and never suffering from any irregularity of the sexual organs, are yet sterile, the exhibition of belladonna internally for some weeks is so frequently followed by pregnancy as to preclude considering the occurrence as a mere coincidence. Though advancing no theory in regard to the matter JONES has noticed that during the exhibition of the drug the external genitals become more relaxed and the labia and clitoris more pliable and softened.

INOCULATION FOR PLAGUE.

We take the following from the *British Medical Journal*:—"W. G. B. writes: I have a friend about to proceed to India, and as he must land, even for a short time, at some one of the ports where plague is present, can I recommend him to be inoculated there before proceeding up country by rail, or will it be unnecessary for him to be inoculated, as he will be for so short a time exposed to the infection? In the event of being inoculated how long would he be so detained before he would resume his journey?"

The *British Medical Journal* answered this query, so Mr. JAMES CANTLIN, who writes: "I would recommend the person

The troops at the Hot Lancers (Princess Pader), who was instrumental in saving the life of Major Pinches, M.A. M.C. is reported to be recommended for the Victoria Cross. Major Pinches had one horse shot under him and another wounded. Princess Pader displayed great bravery in catching two stray horses amidst the derbies in order that Major Pinches might escape.

While Dr. Sheridan was making a vaginal examination of a young woman he had been called in to at Stradone, Ireland, her mother locked the door of the room and then gave him in custody on a charge of rape. The Magistrate completely exonerated Dr. Sheridan who left the court without a stain on his character and was welcomed home by the life and drum bands of the town.

A man who paid a Vienna specialist 147 marks (i.e. Rs. 100) for curing him of tapeworm sued the doctor for a return of 84 marks (Rs. 60) on the plea that the worm was only a short one. The doctor said he did not remove tapeworms at so much per yard; but finally returned 10 marks (i.e. Rs. 6½).

According to Dr. Sebrwald a speed of 12 feet per second or a distance of 25 to 30 miles on the level in one day is quite sufficient for one who rides the bicycle for recreation, and 105 miles per day more than enough for a trained rider, while the maximal riding endurance of trained riders is 322 miles in 24 hours or 24 miles per hour.

The scope of inquiry of the Plague Commission includes the origin of the different outbreaks, the way the disease spreads, and the effects of prophylactic curative serums will be tried. The Commission reaches Bombay by the end of the present month.

Persistent dysphagia of 21 days or more according to Dr. J. Garel, is diagnostic of syphilis and is often the first and only sign the patient notes. Unless it be due to incipient cancer or tuberculosis, the pain in swallowing vanishes with 48 hours' treatment with Potassium iodide.

Colonel F. H. Fenn, R. A. M. C., now at Peshawar, has been offered and has accepted the post of Surgeon to Lord Curzon. Colonel Fenn filled this post during Lord Lansdowne's Viceroyalty, and will be well remembered as an extremely popular member of his staff.

Mrs. Powell, widow of Apothecary William Powell, aged 66, died in the Bangalore city plague hospital the other day, and was buried outside the plague camp by the Rev. W. Muspratt, the authorities refusing permission to bury in the cemetery.

An examination for 23 appointments in Her Majesty's Indian Medical Service will be held in London in February 1899. Copies of the regulations for the examination, and information as to pay, etc., can be obtained on application to the Under-Secretary of State, India Office.

Of all the countries in the world it is Serbia which contains the most centenarians. Among its less than 1,800,000 inhabitants, there are actually 575 persons whose age exceeds 100 years. In little Switzerland there is not a single person whose years number five score.

It has been officially announced from the War Office that the positions of Director-General of the Army Medical Department and of the Veterinary Department will, in future, be held for five years only, unless that period is specially extended for an additional two years.

Surgeon-General W. Taylor, M.D., A.M.S., Principal Medical Officer of the Khartoum Expedition, has been selected to succeed Surgeon-General A. A. Gore, M.D. as Principal Medical Officer of the British Forces at Army Headquarters.

Says the *New York Medical Record*:—The Bengalee have no lunche. Jews as a rule have large ones; the Greeks the thumb only has one.

Major Herbert Jekyl Dyson, I. M. S. L.S.A., London 1883, M.B.S. 1882 F.R.C.S. 1884; Sanitary Commissioner of Bengal, is the son of a well-known Anglo-Indian Schoolmaster of Hooghly in Bengal.

We acknowledge with our best thanks, the kindness and courtesy of Dr. Max Simon, M.D., the Principal Civil Medical Officer of the Straits Settlements in sending us the Civil Hospital Reports of his administration.

We have to acknowledge with our best thanks the kindness and courtesy of the Bengal Government in ordering that the *Indian Medical Record* shall in future be supplied with copies of its Sanitary and Medical Reports free of cost.

Several cases of enteric have occurred here recently among the troops at Poona and Kirkee. A committee of medical men has been appointed to inquire into the causes of enteric fever. It is expected their reports will appear very shortly.

Under the new law any body who sells, causes to be sold or gives tobacco or cigarettes to any person under 18 years of age, will, in New York City, be liable to \$10 fine or 10 days' imprisonment or both.

Professor Tracukel tells of a slightly built virgin, set. 30, whose right breast was 14 and the left one 17 inches in diameter, while the greatest circumference of either was 45 inches.

Lieutenant-Colonel J. Lewtas, I.M.S., Civil Surgeon of Darjeeling, is allowed privilege leave for ninety days, with effect from the 1st December 1898.

Little Doctor Cecil Robert Stevens of Eden Hospital fame, has parted with his "speciality" and has gone to winter in Darjeeling during the absence of Dr. J. Lewtas, the popular Civil Surgeon of that sanatorium.

Charles Monks, L.R.C.S., (Ireland) Surgeon-Lieutenant-Colonel, I.M.S., and Bakshi Isaac Rahim, Kings College, London, passed the second examination of the Board of the R.C.S. Eng. for the F.R.C.S. in Anatomy and Physiology on the 10th October last.

In France it is a punishable offence for any one to give infants under one year any form of solid food unless such be ordered by a prescription written by a legally qualified medical man.

The Prussian Minister of Finance, Herr Von Miquel, has proposed a plan for taxing professors of medicine who also practice. He thinks that any professor enjoying a practice worth \$5000 per annum should receive no salary.

Dr. John William Moore, B.A., M.B., F.R.C.P., has been elected President of the Royal College of Physicians in Ireland, a most worthy nomination. Dr. Moore is the talented Editor of the *Dublin Journal of Medical Science*.

Colonel R. H. Wright, I.M.S., who has been in India a few years ago, has returned to India and has published a fine book on "Ootacamund". He has also written (India's) "Medical authorities on Ootacamund" with new and interesting details.

Dr. H. H. the Indian's Government has recommended the immediate construction of a complete and thoroughly equipped Pasteur Institute for Hyderabad.

The Indian Planter's Gazette says: "Major F. E. Peck (late Doctor) returned from privilege leave on Monday night." Late doctor to be sure!

Dr. W. J. Smyly, M.D., F.R.C.P., has been elected Vice-President of the Royal College of Physicians in Ireland.

It is rumoured that Dr. Arnold Caddy, whether will soon join him in practice in Calcutta.

Assistant Surgeon Amrit Singh, M.B., has been appointed Superintendent of Civil Hospitals in the Nabha State.

Lieutenant-Colonel P. J. Damanis, I.M.S., Bombay, has applied to retire.

Captain W. H. Orr, I.M.S., succeeds Major Wyrille Thompson as Medical Officer, Lawrence Asylum, Banawar.

Section of the cervical sympathetic is the latest mode of treating exophthalmic goitre.

Major O'Dwyer, I.M.S., retires on the 30th November.

Medical Practitioners throughout the Indian Empire, and members of the Local Medical Services are kindly requested to send Original Articles and Clinical Reports of cases for publication in the Indian Medical Record. This must be done if the local medical profession is to remove the reproach being cast upon it of apathy and neglect of its duty in literary matters.

Members of the Indian Medical Association whose subscriptions are in arrears are requested to forward their dues to the Treasurer without delay.

Please send all communications for the Indian Medical Record whether for the Editor, Proprietor or Manager, to 80, Park Street, Calcutta.

Defaulting subscribers to the Record are requested to send in their dues before the close of 1909.

Will all readers of Record kindly return the printed questionnaire sent them for the new Weekly Record.

It has been decided that the Administrative control of the Office of Imperial Bacteriologist shall be transferred from the Imperial Bacteriologist in the Civil Veterinary Department, to the Director-General of the Indian Medical Service.

Dr. H. H. gives it as his conclusion that the safest plan of management of all cases of appendicitis, take them as they come, is the immediate removal of the appendix and the drainage of the infected cavity.

The Committee of the Bengal Chamber of Commerce, in connection with the New Calcutta Municipal bill, have recommended that one of the four Government nominees on the General Committee should be an Anglo-Indian.

According to Webber in the *Lancet*, of twenty-four tetanus patients treated with anti-toxin, twelve recovered and twelve died. The less violent the symptoms the better the results.

We are glad to note that Mr. B. Postonjee, I.M.S., Ceylon, has been admitted a Member of the Royal College of Surgeons, England.

Surgeon-General Harvey, Director-General of the Indian Medical Service, left Simla on 30th October on his autumn tour, which will last six weeks.

Dr. Whitmarsh of London, has been found guilty of having performed an illegal operation, and has been sentenced to death, the jury recommending him to mercy.

Mr. J. P. Hewett will not after all come out in the *Calcutta*, but arrives with the plague specialists about three weeks hence.

Doctor G. H. Joubert, Calcutta's only Gynecologist and Midwifery "professor" has come back to the land of "regrets," and as some Frenchmen say "of regrets."

The University of Paris has been endowed with sufficient funds to enable five of its professors to each take a trip around the world.

Prof. Koch, the famous bacteriologist, is pursuing his study of malaria in the Milan hospitals and intends to spend several months in Italy.

It is stated by a writer of authority, that the insipidity of boiled water may be removed by passing it when cold through a filter, by which it is attained.

Several cases of hydrophobia have occurred at Shanghai recently, and have given rise to an agitation for the muzzling of dogs.

SYMES OF EDINBURGH, LATER SYME.

(From his Practice.)

James Syme, whose name is one of the greatest in the annals of surgical fame, was born on November 7th, 1793, in Edinburgh, where his father had been a Writer to the Signet. He received his literary education at the High School of Edinburgh that "sapient nurse" of so many celebrated men. As a boy he was fond of dissecting animals, and of chemical experiments. At the age of eighteen he discovered a new solvent of caoutchouc obtained by the distillation of coal tar; by means of this he made a silk cloak waterproof, so that, in his own words, it "afforded complete protection from the heaviest rain and could be employed as a pitcher by turning up its skirt." He was fully aware of the commercial value of his discovery, for he characteristically adds: "My friends talked of a patent, but being then about to commence the study of a profession with which considerations of trade in those days did not seem consistent," he preferred to give it freely to the world ("Annals of Philosophy," March 5th, 1818). Not long afterwards the invention was patented by MACKINTOSH of Glasgow.

SYME began the study of human anatomy under Dr. BARCLAY, and he made such progress that in his nineteenth year he was able to take charge of a dissecting room opened by his distant cousin, ROBERT LISTON. His professional studies were, however, somewhat irregular according to the standard of our day when the General Medical Council weighs heavily upon medical mankind. It does not appear that he ever attended a course of lectures on surgery. His training seems to have been almost entirely practical. Thus, in 1820, he was House Physician to the Fever Hospital, a post of honour and also of danger, in which many young men of high promise lost their lives. Afterwards he was resident clerk in the Royal Infirmary. In 1822 he became a Member of the Royal College of Surgeons of England, and visited the medical schools of France and Germany. In 1825 he became Fellow of the Edinburgh College of Surgeons. At that time he was chiefly occupied in teaching anatomy; but surgery was not neglected, for on September 2nd,

1825, he amputated the hip-joint, this being the first time that formidable operations were performed in Scotland. He returned into a partnership with LISTON, but this was speedily dissolved, owing to incompatibility of temper. SYME then, in conjunction with Dr. J. McARTHUR, set up a medical school in which he lectured on anatomy and surgery. He determined to devote himself entirely to surgery, in spite of the fact that his quarrel with LISTON closed the door of the Royal Infirmary against him. Nothing in SYME's life shows better what amount of man he was than the way in which he set about overcoming an obstacle which to a man less strong and less confident in himself might well have appeared insuperable. His lectures had already gained for him some reputation as a teacher, and he had some private means: on the strength of this he established a private surgical hospital, and gave further hostages to fortune by taking unto himself a wife—and also a carriage. His bold strategy was justified by its success.

The report for the first year of his hospital, White House, which had accommodation for 24 in-patients, shows a total of 1,900 out-door cases, 265 in-door, and 95 operations. The reports of this hospital, published during the four years of his occupation, afford striking evidence of his surgical enterprise. Students came in crowds; and as great was SYME's fame that when in 1833 an opening occurred in the Infirmary he could not be refused admittance. On LISTON leaving Edinburgh for London in 1834, SYME remained in command of the field, and he kept it thirty-six years later—with one brief interruption—till his death.

The interruption referred to occurred in 1847, when the death of LISTON led to his being invited to succeed that great surgeon at University College Hospital, London. It is pleasant to think that some years before LISTON had expressed a hope that their "old scores might not be merely plastered over but be soundly clostrised," and SYME had done his part in the healing process. SYME's career in London was short. His first visit to the operating theatre which had been the scene of his predecessor's triumphs, in his own words, "strongly suggested the idea of a bear-pit in the Zoological Gardens." Yet the students, if a trifle disorderly, gave an enthusiastic welcome to their new teacher. But he was never at home in London, and in a few months he found a pretext for resignation in the action of the authorities who wished to burden him with the distasteful duty of delivering systematic as well as clinical lectures. He shook the dust of Gower Street off his feet and returned to Edinburgh, where he was at once reinstated in the chair which he had vacated. Soon afterwards he was elected President of the Edinburgh Medical-Chirurgical Society. Other honours were showered upon him. The title-page of one of his works, published in the early 'sixties, described him as "Surgeon in Ordinary to the Queen in Scotland; Professor of Clinical Surgery in the University of Edinburgh; Member of the General Medical Council for the University of Aberdeen and Edinburgh; Knight of the Danish Order of Dannebrog; Hon. Member of the Royal Belgian Academy of Medicine; Hon. Member of the Russian University of Cracow; Foreign Associate of the Surgical Society of Paris; Hon. Member of the Medical Society of Hamburg; Hon. Member of the Med-

cal Society of Stockholm; Hon. Member of the Medical Society of Bombay; Hon. Member of the Medical Society of Athens; Hon. Member of the Medical Institute of Egypt; Hon. Member of the Royal Medical Society of Edinburgh, etc." He was elected a Fellow of the Royal College of Surgeons of England under the new charter in 1848, an honor which corresponds with the "James I.'s creation" among baronets. The honorary degree of M.D. was conferred on him by the University of Dublin in 1867, and in 1869 by the University of Bonn. Oxford gave him an honorary D.O.L. in 1869.

SYME was still busily engaged in the practice and teaching of his profession and active in controversy when his years were threescore and ten. Then came a stroke of hemiplegia and though he recovered, other attacks followed. He died on June 26th, 1870.

Of SYME's achievements in surgery, only the most cursory review can be given here. He was as has been said, the first surgeon in Scotland who amputated at the hip-joint; he was also the first in Great Britain who excised the superior maxillary bone. He was also the first who performed subcutaneous division of the sterno-mastoid muscle for wry-neck, and who successfully removed a tumour of the clavicle by disarticulating that bone from the sternum. His method of amputating at the ankle-joint is recognized as a great improvement in the surgery of the lower extremity; it may be mentioned that the second case in which he performed this operation was that of Professor GEORGE WILSON, whose account of his sensations on the occasion is a *locus classicus* in the literature of pre-anæsthetic surgery. Some of SYME's greatest operative triumphs were won in dealing with aneurysms. In 1857 he treated a traumatic aneurysm of the carotid too low for proximal ligature by incision and ligature at the wound. In 1859 and 1860 he cut into two large axillary aneurysms, and tied the artery in each case at the spot successfully. In 1861 he treated two cases of gluteal aneurysm, one by the old operation, the other by the Hunterian, both successfully. In 1862 he cut into an iliac aneurysm and tied the common internal and external iliac arteries. In 1897 he published the thirty fifth of a series of successful cases of ligature of the superficial femoral for popliteal aneurysm. He twice at least performed amputation at the shoulder joint successfully for aneurysm. He was a pioneer in the excision of joints; he did much to rescue diseases of the rectum from the hands of quacks; he was a successful lithotomist and improved the treatment of urethral stricture. To him also we owe some of the earliest researches on the formation of new bone from the periosteum. Of his surgical works, two at least may be read with the greatest profit at the present day. His "Principles of Surgery," which was first published in 1832, is one of the most remarkable books ever produced on the subject, and even from the purely literary point of view may be commended as a model of terseness and lucidity of style. It is characteristic of SYME that this book, instead of growing in bulk in successive editions, became smaller each time the author had the opportunity of pruning away what he considered to be redundancies. In 1847 he collected his miscellaneous writings in a volume entitled "Contributions to the Pathology and Practice of Surgery." In 1866 he delivered the address on surgery at the annual meeting of

the British Medical Association, which was held that year at Leamington. One of his last contributions to surgical literature was a paper entitled "Illustrations of the Antiseptic Principle of Treatment in Surgery," which was published in the *British Medical Journal* (1896, vol. i.).

As a surgeon, SYME was the incarnation of the hardheadedness and caninness characteristic of his nation. He was not showy, but he was sure—alike in judgement and in execution. As an operator he never made any display, but he knew what he meant to do, and he did it quietly and effectively. He thought only of the patient, and, whatever the emergency, was never hurried. Of his extraordinary power as a clinical teacher the best proof is the fact that he left his mark on a whole generation of teachers. In addition to the principles and methods which he taught his pupils, he was in himself a constant lesson to them of scientific honesty and straightforward simplicity of character. No man was ever less of a charlatan. In his later years he was, perhaps, a little too suspicious of novelty, but he was always open to conviction, and he was one of the first to recognise the importance of the work of his distinguished son-in-law, Lord LISTER.

Though to strangers his manner was cold, this was due to shyness, and to the fact that, like the Iron Duke, with whom he had a good deal in common in the character of his mind, he had "no small talk." He was a man of genuine kindness of heart, and was most genial to those whom he knew well. His one "hobby" outside his professional work was a fondness for flowers; he was a successful as well as an enthusiastic horticulturist.

SYME was one of the first members of the General Medical Council, and he was a great advocate of medical reform. He was a man of strong opinions, which he was given to expressing in strong language, and was rather apt to see in difference of opinion a proof not only of intellectual deficiency but of moral depravity. He was ever a fighter, and battered his enemies with pamphlets which are now happily forgotten.

In person SYME was below the middle height, but of well-knit, active frame. His hands were small and not very powerful, but he could make them do what he wanted them to do. The best description of the real man is that given by Dr JOHN BROWN in "Rab and his Friends";—

"Everywhere, personally, professionally and publicly, reality is his aim and attainment. He is one of the men—they are all too few—who desire to be on the side of truth rather than to have truth on their side, and whose personal and private worth are always better understood than expressed. It has been happily said of him that he never wastes a word, a drop of ink, or a drop of blood, and his is the strongest, exactest, truest, immediatest, and shiftest intellect dedicated by its possessor to the surgical cure of mankind I have ever yet met with. He will, I firmly believe, leave an inheritance of good done and mischief destroyed, of truth in theory and practice established, and of error in the same exposed and ended, such as no one since JOHN HUNTER has been gifted to bequeath to his fellow-men. As an instrument for discovering truth I have never seen his perspicacity equalled. His mental eye is achromatic and admits into the judging mind a pure white light, and records an undisturbed, uncoloured image, undiminished and unaltered in its passage, and he has the moral power, courage, and conscience to use and devote such an inestimable instrument aright."

FEBRUARY SEANITION OF CALCUTTA.

Statement of Diseases from Principal Hospitals in Calcutta during the week ending 11th October to the 11th November 1905.

Week ending.	Cholera.	Typhoid.				Small-pox.	Fever.	Howl complaints.	All other diseases.	Total.	Total population of Calcutta.	Deaths per 1,000 of the population per annum.

Current Medical Literature.

MEDICINE.

Angina Pectoris: Its Diagnosis and Treatment.

HORATO C. WOOD, thinks that if true angina pectoris be due to increased intraventricular pressure the arterial system and not the heart should play the chief role; digitalis must be death to the heart in angina-pectoris since it is opposed to aortic which can altogether do away with intraventricular pressure and nitrate of amyl which relieves the aorta and takes away the resistance of the heart. *REDDO (Phil. Monthly Cyclop of Practical Medicine)* insists on true angina pectoris being always associated with cardiac lesions which do not always yield appreciable physical signs of their existence while, autopsy alone discloses and lays down the following as most reliable for differential diagnosis.

TRUE ANGINA.
PECTORIS.

- (1) Is very rare before the age of 40.
- (2) The pain commences always in the heart.
- (3) The attacks are infrequent and patient likely to succumb in the second or third attack.
- (4) It is generally induced by effort, emotion and disorders of digestion.
- (5) It occurs in the day time.
- (6) The sufferers are pale and can neither stir nor breathe.

PSEUDO ANGINA
PECTORIS.

- (1) May occur at any age.
- (2) It is ascribed to the arm and radiates in several directions.
- (3) Are common and *per se* seldom fatal.
- (4) By malaria, rheumatism, infectious disease &c.
- (5) Generally nocturnal.
- (6) They are agitated, get up from bed and run to the window for fresh air.

FRUCH (La Riv. Medical) noticed a peculiar musical heart-sound resembling a feeble groan or the chirp of a chicken and J. H. MURRAY (*Amer. Jour. Med. Sci.*) who thinks the pain is chiefly due to increased intraventricular pressure, infers the presence of dilatation of the heart by the physical signs of displaced apex-beat, gallop-rhythm, a soft regurgitant in the tricuspid or mitral area, by venous phenomena and by the congestions, cyanosis and dropsy that attend angina pectoris.

FRUCH (La Riv. Medical) noticed a peculiar musical heart-sound resembling a feeble groan or the chirp of a chicken and J. H. MURRAY (*Amer. Jour. Med. Sci.*) who thinks the pain is chiefly due to increased intraventricular pressure, infers the presence of dilatation of the heart by the physical signs of displaced apex-beat, gallop-rhythm, a soft regurgitant in the tricuspid or mitral area, by venous phenomena and by the congestions, cyanosis and dropsy that attend angina pectoris.

calcification of the coronary arteries suggests dilatation of these arteries by increasing the elimination of the lime by putting patent on a diet that is poor in lime and giving potassium acid internally while *MURRAY (Amer. Jour. Med. Sci.)* finds that digitalis is of doubtful value and thinks that it should not be given in angina pectoris unless an excess of dilatation be present.—*Med. Rec.*

Non-Surgical Treatment of Boils,
Carbuncles and Felons.

ADJUSTING the profession to bear well in mind the salient fact that though microbes can produce many diseases, there is a disturbance—not always easy to determine in nutrition before every illness, and microbes can only act where the health has deteriorated through various pathogenic processes. Dr. L. DUNCAN BULKLEY cautions against the too free use of the knife and puslites, both of which he has avoided for over ten years as boils, carbuncles and felons in the majority of instances are but suppurative external indications of deeper seated disease and patient persistent investigation helping to elicit the particular departure from health will generally afford the line upon which successful treatment will rest. The cause may be in overwork, worry, dissipation involving late hours and irregular feeding, or it may depend on assimilative and digestive difficulties, where iron is chiefly needed. Sulphide of calcium if perfectly good and fresh may be given with advantage and *STANTON'S* mixture (Ca. R. Ferri Sulph. 3j, Mag. Sulph. 3vj, Acid Sulph. Oil 5vj, Syrup Zinziberis 5vj; Aque ad 3ij. Sig. teaspoonful after meals) preceded by a good mercurial purge (R. Pulv. Iodine grs. ii, Masse hydrargyri grs. x; Ext. Colocynth Co. gm. and Div. in pil. no. iv. Sig. 2 first night and remainder next night) will work wonders. With these measures and careful attention to diet and mode of life the tendency to suppurative processes may be quickly overcome.—*Gaillard's Med. Jour.*

Intermittent cold in Typhoid Fever.

As the continuous use of the ice-bag tends to congestion or sloughing of the skin A. J. DOWNES places the ice-bag for 90 minutes at a time over the ileum and beginning of the colon and removes it for 30 minutes; but if the temperature rise to 108°F. and over the ice-bag is removed for only 30 minutes at a time. In either case the time during which the ice-bags are on and off amounts to 2 hours and sponging the body with ice-water and alcohol during the intermission forms an essential part of the treatment. So long as the temperature exceeds 102°F. two spongings daily should be given. J. MURRAY GIBBS (*Austral Medical Gazette*) attains alternate freezing and thawing by placing his patient on a tube mattress, and covering him with a second one. Cold water, a sepioid mixture or water heated to various degrees of temperature is forced through the tubes so as to gradually bring the air surrounding the patient to the required temperature, just as is done in cold-storage houses. *Therap. Gazette.*

SUMMARY.

Successful Treatment of Typhoid Fever.

At the notification of focal accumulations in the form of diarrhoea, severe constitutional disturbances, tympanites, abscesses and even perforations of the extremely tender and inflamed typhoid bowel as well as result in exhaustion and death. Culture obtains from all active interference except the control of hemorrhages or active diarrhoea; but though the regrets that there is no sign pathognomonic of intestinal perforation which occurs in at least 2 per cent of typhoid patients and proves fatal in 44 per cent of such cases, FINNEY (*Johns Hopkins Hospital Bull.*) notes that the last 2 feet of the ileum is the most common seat of this lesion which is usually accompanied by a marked increase in the leucocytes found in the blood at the time, when the white corpuscles should have sunk to their lowest point; but he places most dependence, for diagnostic purposes, upon sudden acute pain in the abdomen accompanied by symptoms of collapse and an abrupt fall in temperature, and says that the best time for operative interference is immediately after the patient recovers from the shock attending perforation, when the ileum should be first overhauled and a suture taken over all suspicious looking patches, though there is no absolute necessity to prolong the operation by paring the edges of the perforation, while MORON and VANVERT endorse these views and declare for surgical intervention immediately after perforation is suspected. JOHN B. DRAVER urges that to wait operative measures till full corroborative evidence of perforation obtained is culpably fatal, as septic peritonitis with an abdomen filled with pus is sure to follow and end in death.—*Rev. de Chir.*

Modification of the Technique of Vaginal Hysterectomy.

DR. DOYEN read a paper on this. He said that he had been obliged to remove the uterus by vaginal hysterectomy in cases in which the adnexa has been removed by laparotomy and now he performed total ablation. Three operations might be performed per vaginam (1) simple incision into the pus focus (2) unilateral ablation of the alveola (3) total vaginal castration. In performing laparotomy, he used the Trendelenburg position. In vaginal hysterectomy, he crushed the broad ligaments with special forceps, and left the forceps on for forty or fifty seconds. He closed the peritoneal cavity entirely.

Venesection.

KAUFE begins a study of this subject. He refers to the authorities who have recently advocated venesection in certain cases, and first discusses its use in acute pneumonia. The effect of oedema of the lung, or a very massive exudation compressing the capillaries, is such as to cause an insufficient exchange of gases, thence a co-intoxication. With this is associated a mechanical difficulty. For a time the reserve force of the right ventricle can overcome these difficulties, but when exhaustion sets in there is dilatation, and then commences the danger to the patient. The blood is driven into the left auricle with difficulty, and the heart muscle is insufficiently nourished. The pressure in the pulmonary circulation increases, and that in the aorta diminishes. To overcome these dangers two expedients are had recourse to, namely, (1) to increase the power of the right ventricle by stimulants and cardiac tonics, and (2) if this does not succeed, to reduce the mass of the blood by venesection. Often venesection then produces a diminution of the cyanosis and of the dyspnoea, and the pulse gains in strength. The author believes that the best time for venesection is near

the turn of the crisis. It should be repeated if necessary. He refers to three apparently identical cases in which venesection was followed by recovery. Again, in acute pulmonary oedema of the heart and lungs the pulmonary circulation may become overloaded. Here venesection may give even better results than in acute pneumonia. Occasionally in heart disease sudden exhaustion may occur in a heart patient acting relatively well. Cyanosis, smallness of the pulse, intermitting respiration, may lead quickly to death. By a venesection the right heart is relieved. The author refers to two such cases. The one occurred in a man, aged 53, who was seized with sudden and most severe dyspnoea. After a bleeding to 200 c.cm. the cyanosis rapidly disappeared. In the other case a girl, aged 16, with heart disease, was suddenly seized with great cyanosis. The radial pulse could not be felt, and there was Cheyne-Stokes breathing; 380 c.cm. of blood was withdrawn, camphor injections given, and artificial respiration practised. On the following morning there was no trace of the severe symptoms of the day before. There is a group of cases in which the cardiac tonics do not act satisfactorily. The author refers to one case in which the patient appeared almost moribund. Digitalis failed to relieve him until venesection had been performed, when it yielded the best results, and the patient lived for two years.—*Brit. Med. Jour.*

Scientific Treatment of Chronic Gonorrhoea.

VALENTINE has published an article upon "Chronic Gonorrhoea," of which the following is a summary:

1. There are no incurable cases of chronic urethritis.
2. All drugs suggested for the treatment of chronic gonorrhoea are soon relegated to merited oblivion.
3. The only efficacious method of treating chronic gonorrhoea is by dilations, as proposed by Oberlander, followed by irrigations, without a catheter, of the urethra or bladder or both.
4. Urethral fever or other disturbance does not supervene after urethral instrumentation followed by irrigation.
5. Carefully conducted dilations and irrigations are not painful.
6. Gradual, careful pressure by dilators is preferable to the use of sounds in the majority of cases.
7. The effect of dilations is to stimulate absorption of the infiltrations.
8. Functional disturbance and nervous symptoms are improved very early in the treatment.
9. Chronic urethritis can be exceptionally diagnosed and successfully treated, but never pronounced cured without the aid of the urethroscope.—*Med. News.*

Exophthalmic Goitre Treated by Resection of the Two Cervical Sympathetics.

GERARD-MARCHANT treated a patient with exophthalmic goiter by resection of the inferior portion of the right and left superior cervical ganglia with about two inches of the nerves, an improvement in the eye condition was noticeable almost immediately, and this increased until the exophthalmos was very slight indeed. The pulse decreased from 80 to 100 to a constant rate of 80.

In the same number of this Journal, CHAUFFARD mentions a similar case occurring in a man. Quenu performed a bilateral operation as above described. The immediate results were scarcely noticeable. Two and a half months later an attack of tachycardia came on, and the patient was given a bottle of digitalis with instructions regarding its use. He took nearly the whole contents of the bottle, and died some hours later of acute digitalism. Therefore, he lived long enough to demonstrate the failure of the operation.—*Med. News.*

OBSTETRICS AND GYNECOLOGY.

Senile Uterine Catarrh.

COMPLAINING that text books have too little to say of this condition which occurs in one of three forms:—(1) foetid discharge without hemorrhage (2) leucorrhoea with slight hemorrhage and (3) those in which hemorrhage is the main if not the only symptom, J. KALLIDAY CROON M.D., F.R.C.P., lays down the following points for differential diagnosis between malignant disease and post-climacteric hemorrhage—

In primary cancer the (1) uterus is sensitive, distinctly enlarged, early becomes fixed and heavy and (2) presents neoplasm and other irregularities, while (3) periodic and severe pain is an early and prominent symptom and (4) real floodings are very common; but (5) foetid discharges are unusual in the early stages because the os is closed and the surface of the cancer protected from external influences, hence (6) medicines fail and operation is imperative.

Whereas in senile uterine catarrh the (1) uterus is normal or only slightly enlarged, freely movable throughout and (2) presents no irregularities while (3) the pain is either irregular and colicky or slight and constant and (4) real floodings are less frequent and less severe, but (5) the foetid discharge is an early and prominent symptom and (6) operation is very seldom needed as appropriate remedies cause rapid improvement in from 7 to 14 days.

While he insists that senile uterine catarrh is not prodromatic of cancer he finds it wrong to prophesy that a woman who has been free from uterine affections during her menstrual life will continue to remain so after her menopause when the organs usually atrophy. For treatment he advocates rest, hot douches and the administration of arsenic, straphanthos and chian turpentine, but thinks nothing more beneficial than the application of ecbolonica by dressed sounds or, better still, curettage of the hypertrophied, succulent and easily detachable mucous membrane, with subsequent packing and drainage.

Treatment of Ectopic Gestation.

Dr HAGGARD concludes a communication on "Ectopic Gestation" with the following recommendations—1 In unruptured ectopic gestation the vaginal operation, if congenial to the surgeon, may be elected 2 In non active cases of encysted hæmatocele vaginal section and drainage is the operation of choice 3 The situation of the mass low down, and the broad, roomy vagina of parous women are favourable to the lower route 4 Before evacuating ectopic collections *per vaginam* preparation for abdominal section should be made 5 In free or uncontrollable hemorrhage, after removing the products of ectopic gestation vaginally, the abdomen should be opened at once 6 When abdominal section is necessary after colpotomy the preliminary vaginal incision (a) will confirm the diagnosis, (b) facilitate the abdominal work by removing clots through the vagina instead of through the abdomen, and (c) establish an efficient avenue for drainage 7 The vaginal operation in appropriate cases is attended with less mortality.—*Amer. Gyn. and Obst. Jour.*

Pessary in the Uterus for Fifteen Years.

R. M. DAVIS places on record the case of a woman, aged 76 years, who had long suffered from leucorrhoea. It was thought from her age and the foetid nature of the discharge that cancer of the uterus existed. In the vagina a metallic stem was found passing into the cervical canal, and the patient recollected that fifteen years previously a pessary had been inserted for prolapse. It was found impossible to

withdraw the pessary, as the distal portion of it was imbedded in the cervical tissues. A *Wilmart's* incision was made in the anterior vaginal fornix the bladder was stripped off, and then the cervix was divided with scissors in the median line and the foreign body removed. There was parietal endometritis, and so douches were used and the vagina packed with iodoform gauze. There was complete recovery. The pessary must have been sucked into the uterus.—*Brit. Med. Jour.*

Pathology of Eclampsia.

A STUDY of 800 cases shows that hemorrhage is the distinguishing feature of the changes found in the various organs, and that among the complications broncho-pneumonia and cerebral hemorrhage are the principal causes of death. Bacteriological investigation results negatively except in mixed infection. Chemical investigation of the blood and of the toxicity of the urine and serum is still in the preliminary stages, and the present knowledge of eclampsia does not justify sweeping conclusions in regard to its etiology. In 368 cases only 7 had sound kidneys, there was nephritis in 46 per cent, chronic inflammatory processes in 11.6 per cent. Changes in the liver, mostly hæmorrhagic, were noted in 218 cases. Hemorrhage into the brain was noted in 28.4 per cent, intracranial hemorrhage in 35.3 per cent. The stomach, intestines, spleen pancreas, suprarenals, and genitalia are also frequently found to have been the seat of hemorrhage, and even the skin, mucous membrane, muscles, serous surfaces, and thyroid gland.—*Monthly Cyclopaedia.*

The Curette after Abortion and Delivery.

BUTNER has observed 28 cases where the operator was GLAEVCKE. He finds that the use of the curette is free from danger if carried out with proper precautions. It permanently stops hemorrhage after abortion or delivery, and, as a rule, the catamenia return soon, and continue normally, contrary to what is so often seen in mismanaged cases. A skilful use of the curette likewise prevents those morbid changes which are the cause of sterility.—*Brit. Med. Jour.*

Functional Activity of the Mammary Glands of an Infant.

Was noticed by Dr. J. B. GRAVER in a baby girl, who was born on 28th January 1898, but was just a week old when her unusually developed mammary glands began to secrete so abundantly that her mother is obliged to pump the milk out of both glands at least once daily and till this was done the babe was very fretful. This milk appears identical with mother's milk and the child is robust and as well conditioned as healthy babies are at her age.—*Med. Rev.*

Living Premature Infants.

In proof of the premise that a strong premature infant can clear the pulmonary vesicles and liver, VILLENIN (*Ann. de Gyn. et de Obstet.*) showed the Paris Obstetrical Society a fine mentally and physically developed child aged 31 months which weighed 366 grammes (less than 2 lbs) at birth in the 5.3 or 6 months of gestation but was brought up by the *conscience* and careful feeding. CHAMPREDON also reared up an infant that weighed 37 ounces at birth when its respiration was purely bronchial.—*Brit. Med. Jour.*

BARBERS AND BARBER SHOPS AND DISINFECTANTS.

A Sanitary Barber Shop.

Barber shops are the conditions existing in barber shops are responsible for the spread of many diseases, not only of the skin, hair, and beard, but infectious maladies as well. It suggests the following rules for practical guidance of barbers and legislators, since he considers that a barber shop is properly subject to public control. The barber himself should be free from epilepsy, spasms of any kind, drunkenness, and infectious diseases. Persons afflicted with contagious diseases of the skin, hair, beard, or genitals, should not be allowed in a public shop, but should be attended to at their homes, where they should have all their own instruments. In the shop all brushes and combs should be made of good material, so that they may withstand frequent disinfection. Full balls should be replaced by balls of absorbent cotton, which should be thrown away after they have been once used. Towels, etc., should be freshly laundered for each person, unless paper napkins are employed and used only once. Combs should be cleaned and disinfected with corrosive-sublimated solution after each use. Shears, razors, and clippers should be boiled or wiped thoroughly with alcohol after each use. A barber should never wipe the razor upon his hand. Brushes to dust away the cut hair from the neck should be forbidden. A barber should pay special attention to the cleanliness of his own hands and person, and should be instructed in the appearances of diseases of the skin, scalp, beard and genitals.—*Med. News.*

The early training of the Mentally Defective.

BERNARD considers the early training of the mentally defective of the utmost importance. The evidences of departure from the normal may be detected in infants at the beginning of life by a careful study of the unconscious and instinctive muscular actions, and the mode in which the various child-emotions are expressed; also by the process of growth—muscular, physical, and mental, and by carefully studying the powers of speech at the age of speech-development. BERNARD advises methods of corrective suggestion and appeals to imitateness in order to gradually guide the pathologic toward the physiologic. This should be accomplished through the adoption of a well-ordered and comprehensive domestic treatment, begun with the earliest recognition of any pathologic condition. Early mental sanitation diminishes the frequency of occurrence of insanity. The creation of a "time-table" for infants is advised, including rules for guidance before dentition, during and immediately after dentition, and rules to apply up to the third and fourth years of life, at which stage the books for the mentally defective now in use can be applied.—*Phil. Med. Jour.*

Treatment of Poor Patients in Sanatoria.

HUTTEN and BRAULOVN urged the necessity of treating indigent sufferers from tuberculosis in sanatoria on the following grounds: (1) The sanatorium ensures the isolation of the patient, who otherwise constitutes a danger to society; (2) the sanatorium alone, owing to its special arrangements makes it possible to give the tuberculous patient the care which he needs; (3) the sanatorium, which is especially indicated for the more curable cases, affords a means of sealing a substantial financial and social gap, as has been shown by the results obtained by Assurance companies against invalidity; and old age isolation hospitals and pavilions as at present constituted meet only one of the requirements of the case, namely, that which has reference to the danger to society caused by the tuberculous. They have the serious drawback that they necessitate a very heavy expenditure

which would probably not be recovered by the creation of sanatoria, which seem to afford satisfactory solution of the problem. Every effort should be made by the medical profession to send to sanatoria tuberculous cases at the beginning of the disease, when they offer the best chances of cure. With the view of securing this object, the question of providing for the support of the families of the patients during the stay of the breadwinners in sanatoria will have to be considered.—*Brit. Med. Jour.*

Milk: its Absorption vs. its Digestion.

MILK alone is sufficient to meet the needs of the body. Intravenous injection of fresh milk has been safely practiced, showing that the economy can assimilate it without previous digestion and absorption. Working on this theory, the author has adopted the following plan for the rapid absorption of milk without previous curdling and digestion. A number of hours after a meal (usually three or four) the food disappears from the stomach, with all gastric juice and the mucous surface becomes alkaline. This is the "alkaline tide" of the stomach. If at this time milk, free from fat, fresh and alkaline, and at the temperature of the body, be taken, it will excite no secretion of gastric or pancreatic juice on account of its freedom from all irritant qualities, and it will, therefore, pass at once in an unaltered state into the absorbents and system. This saves nature much work and avoids the disturbances of coagulation. It enters the blood-current more quickly, and in no way disturbs the appetite for regular meals, even increasing the latter. Milk can thus be taken by patients who cannot take it with their meals. *BULKLEY.—Monthly Cyclopaedia.*

Euthanasia.

SWAN-LIKE the wild Indian chants his own requiem and stoically meets the grim destroyer; while viewed from its most favorable aspects by civilized races death is intensified by abject fear, and depicted as a horrible ordeal accompanied by agonizing pain, wasting and hopeless struggling to resist the king of terrors; but as Dr. O. C. MARSH truly points out that no matter how intense the individual's previous suffering may have been, final dissolution in over 90 per cent. of human beings is utterly painless and is immediately preceded by a blissful unconsciousness, which may last for a few minutes or for several hours, while the mysterious force we call life slowly takes leave of its last citadel, the heart.

Many things legally right are morally wrong and vice versa, and instead of being mercifully and without their knowledge passed from suffering into rest by a fatal portion when all known palliative measures have failed, persons going through the mental and physical agonies of incurable affections and painful diseases and deformities which make life unbearable and themselves a heavy burden on their friends and relations, are condemned to either suffer on and on in vain, longing for relief in final dissolution which will not come in *rerum natura* or seek relief in suicide.

Excessive pain blunts, hardens and brutalizes the spirit of man and if as clinical critics assert God sends pain to discipline and purify us, the discoverers and employers of ether, chloroform and other anesthetics are guilty of blasphemous impiety. "Look" says Dr. MARSH "at the thousands of diseased, suffering, tortured human beings who crawl on and cumber this fair earth as the offspring of human ignorance, brutality, guilt and shame. Walk through the insane asylums. Go to the children's hospital and see the poor little innocents maimed, racked and tortured from no fault of their own. It is preposterous to think that God loves to behold the agonies of infants or to afflict them with terrible wasting diseases without the possibility of permanent restoration or even relief by speedy death." Brute creation recognizes while reasoning man ignores that it is the acme of kindness and wisdom to put such sufferers to death; but to either kill such beings or let them kill themselves, equally infringes the law which has not yet reached that just stage of perfection that should ordain that when a committee of competent medical men have fully decided that an afflicted person is utterly beyond all hope of cure though he may linger on in agony for months and years it were wiser to quickly dispatch him than to cruelly prolong his suffering by deferring the death he hourly and daily prays for to terminate his pain.—*Med. Age.*

fire of disloyalty has been secretly smouldering and even now may burst into flame, unprovoked, in the devastation. India is not in such a condition of security as we and her best friends should wish to see her. Let our great advocates and leaders remember our words at Calcutta when they meet in Conference, and decline to be shamed by a law of effacing Government. Our rulers will not object to consider, if it be legitimate, or to expressions of opinion, if they are discreet. Our exponents should do their duty fearlessly, yet temperately. They will have before them an opening that, if rightly followed up, may lead to an Annual Congress that ere long may prove itself a valuable auxiliary to our home Parliament. We have received an assurance that we are to be there, though subsequent enquiry has not elicited any further information. Whether we are there or not our duty is plain. We urge upon our friends to insist upon their rights, not as favours, not as concessions, or privileges, but as claims upon a Government that but for them would inevitably have collapsed in 1857-58. India was being wrested from British dominion when Anglo-India, in her non-combatant communities, stepped boldly forward, cast herself into the breach and helped our brave soldiers, shoulder to shoulder, to recover a possession that England felt was slowly yet surely slipping through her fingers and upon which her grasp had been most materially loosened. If we avail ourselves of what this Conference will indubitably offer us—an opportunity for amalgamating our forces, and of meeting annually for purposes of self-protection—a great and creditable work will be done and our labours will result in a well deserved triumph. Our representatives should bear all this fully in mind."

Let the Government of India and the India Office be careful how they make their next move.

Yours &c., ANGLO-INDIAN.

TRUE ANGLO-INDIAN LOYALTY. THE IMBECILE CRY OF THE SATURDAY JOURNAL.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

RETURNED on to an eloquent defence of Anglo-Indian loyalty by the recent strictures of the *Record* on that journal's imbecile remarks, *The Bengal Times* gives utterance to this noble and fearless exposition of the truest sentiments which actuate the Domiciled British Community of India in its action towards the Government:—*The Bengal Times* say:—

"Quoting from a weekly contemporary—*Saturday Journal*—of Calcutta, we note:—

"The plague has left Calcutta, and the unpleasant controversies that have arisen in connection with it may very well be dropped. There is, however, one indirect issue arising out of the wicked charge levied against the Government of manufacturing plague, that I would like to draw attention to. The statement weakened the hands of the authorities in dealing with the natives, large numbers of whom, already violently opposed to the plague regulations came to believe that the Government was acting merely from a capricious desire to annoy. Now, is it, or is it not the duty of every European in this country, or all who have white blood in their veins, to rally in times of danger to the support of the Government? A

weekly medical paper, published in Calcutta, and circulating among Anglo-Indians and the following is the substance of the notification regarding Calcutta as issued by it:—"No More Official Plague in Calcutta. The Government Declaration that the City is Free. Official Plague Station factory still to be kept open." One of the first actions of the Anglo-Indian and Eurasian community to the consideration of the Government, has been its steadfast loyalty to the Crown. I hope, then, that the leaders of that community in Calcutta and elsewhere, will come forward to publicly disassociate themselves from these persistent efforts to charge the Government with lying and fraud, and to play into the hands of the most seditious and disaffected sections of the native press."

"Heartily endorsing what our Saturday contemporary advances that all plague controversy may now cease, we are unable to agree with him in his strictures, as respects Government and our domiciled Anglo-Indian community, in their relative positions; that is, if he really intends to convey what his words seem to imply, which we apprehend he does not. It is his desire, doubtless, to deprecate further attempts to impale Government as having, under official authority, excited panic and an altogether unjustifiable stampede amongst several classes of natives; and he advises that Europeans should cease to give currency to this charge; but his words have been unhappily chosen, his inelegant, ungrammatical sentences incongruously grouped, so they may be read as giving a different meaning to his exhortation. No sensible person can, for one moment, doubt that, our Anglo-Indians have been badly treated; that their merits have been overlooked; that their just aspirations have been rebuffed by an irritating reiteration, disclaiming power to confer preferment, and by a doubtful allegation that, power as regards Indian patronage, has been monopolised by our Secretary of State for India, hence that natives of India—meaning natives of aboriginal descent, without European connection, are preferred to those of European blood; nevertheless, we should never advise anything like desertion of our old flag, in order to promote sedition amongst natives. Our first claim as her Majesty's subjects, because of our loyalty—which goes without saying—is on her representatives out here; not because we have been and are loyal, in any abstract sense, but because our permanent stay in India is in some measure, a deterrent to open resistance to constitutional display, and properly considered enforcement of authority. It is, and can never be otherwise than assumed that, we are one with our rulers in the cause of peace, good order, and just and efficient administration; that whoever might hesitate, we at all events, could never be otherwise than true to our national traditions, and that our chivalry, not to call it our patriotism, would revolt at seeing our sovereign defied through those to whom she has entrusted authority; and its unnecessary to add, this would, in any case, be a natural feeling amongst us. It seems to be somewhat superfluous to counsel us how to comport ourselves in any emergency, no matter how startling. We can never forget who and what we are, and how our status has been won for us by our ancestors; how we have inherited rights sanctified by the voluntary self-sacrifices of heroes and martyrs, or how it behoves us to maintain them in their integrity. Why should we seek to nullify our

On 12/15/68, I was told that I had been named in either a letter of reprimand or a letter of censure issued in connection with my complaint in the "Smoking Report," which I did not notice anything that did not come through the office of the Civil Service.

1907-8. DESPAIR.

(You should immediately recall your submission and submit printed memorials through your civil surgeon to the Director General I. M. S., the Inspector General of your Circle and the Local Government. If the Civil Surgeon refuses to forward your memorial, lay your case before the Local Government directly and in the event of your not thereby obtaining redress, we will turn the Indian Medical Association will do its best to help you. -- 22 I. M. S.)

**AN INDEPENDENT MEDICAL COLLEGE IN
BOMBAY.**

TO THE EDITOR, "INDIAN MEDICAL RECORD."

Sis.—The following letter speaks for itself. It was the direct outcome of a comment on it by the *Times of India*, of what appeared a bogus institution:

"Sir.—As I have been appointed by the Independent Medical College, Chicago, to be a member of their Representative Committee in Bombay, it is my duty to give an explanation to the leader which appeared in your yesterday's issue.

The authorities of the Independent Medical College have decided to have a Representative Committee here, in order that the business may be carried out in a legitimate manner.

Since some time back the rumour is circulating that the M. D. degree of that College can be obtained by anybody on payment of £20. To prevent such frauds some persons have suggested to the College authorities the necessity of having a committee who would select candidates for the examination and supervise it.

The following is an extract from a letter Dr. PATHARE, one of the graduates of that College, received from the Principal :—" We have decided to send to India two of our professors, Drs. Z. A. VAN NOPPEN and FRANK E. LING, to investigate possible frauds and further abuse. Moreover, they will be there expressly for the purpose of establishing in India branches of our institution."

When the two Professors (who are expected in November next) will be here, the committee will be composed of the following persons, including myself :—Professor D. A. L. VAN NOPPEN, Ph.D., M.A.; Professor FRANK E. LYON, M.P.; Dr. D. KHOTI, B.A., L.M. & S.; and Dr. N. PATHAK, M.D.

Now our duty will be only as supervisors and not as examiners; of course the oral will be conducted by the two Professors. I enclose herewith a leaflet on which is printed the rules and terms under which candidates will be admitted, &c. I hope you will publish it in order that the public may see the conditions.

The rules, as you will see, will not give an easy opportunity, as is believed, to each and everybody to obtain that degree.

Let us now wait for the nature of the questions and

The results before we can have an estimate of the value of the game.

Yours, Wm. LIONEL D. BROWN

BYDOLL 3, RIFON ROAD, 2804, Ocala

Here follows the Times of India comment on the above letter:-

"Our invitation to the organization of the examination to be held in Bombay under the Independent Medical College of Chicago has not been without result. A letter which appears in another column in explanation of the undertaking partially satisfies curiosity on the subject, but it leaves something unexplained. Thus, the gentleman who vouches for the *bona-fide* character of the examination, has done himself the injustice of leaving the public to suppose that he is a medical man. Yet Mr. LIONEL D'AVOINE is modest enough to lay claim to no medical title. He is, we understand, a gentleman who, having been born and brought up in Mauritius, has not yet had the opportunity of obtaining a degree. But he has gone through three or four years' useful toil in a Mauritius hospital, and is just so much of a medical man as that experience has made him. Doubtless when we have Dr. Z. A. VAN NOPPEN and Dr. FRANK E. LYON from Chicago sitting in an upper chamber in Maragon, assisting two local medical men and the gentleman from Mauritius to supervise this examination, we shall have an imposing array of talent and professional prestige. All the same quite enough has been said here about the Independent Medical College of Chicago to enable medical students in Bombay to judge what its degrees are worth."

Now Mr. EDITOR, what is your opinion of this new movement?

Yours. &c., A BOMBAY L.M. & S.,

(We cannot omit that we have the smallest remnant for irresponsible claims of this stamp. On the very fact of it, this stamp in a number bears the stamp of irresponsibility and deserves to be publicly condemned. It would never do to have an American diploma so ill inaugurated in this country. We are positively certain that every respectable Medical College in America will disapprove of the tactics of this invertebrate corporation which offers to do business in medical examinations and diplomas without any other conditions than that the applicant be a man and that he be secretary, who himself is not a qualified medical man.—Eds. L.R.B.)

TOBACCO-ASH IN COBRA-BITES.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Referring to the queries raised by Mr. RAN DHAN SINHA L. T. M. S., on page 254 of your 16th October 1936 issue, I would call his attention to the fact that the tobacco-ash Mr. TRIBHUNAL MAGANLAL C. M. S. alludes to on page 245, is not merely burned tobacco leaves, but the mineral residue obtained by the slow combustion, in presence of inspired azote, of a combination of tobacco leaves with *gour* (i.e., unclarified country sugar) cubes, lime, and certain odorous mixtures, whose composition is preserved as a trade secret.

I have not had the time nor opportunity to chemically examine all the various kinds of tobacco prepared for hookah smoking, but a large number of those that I have analysed, contained varying proportions of nicotine, picric acid, narcotine, apium, choline, guanine, calcium chloride, potash and sodium salts in combination with chlorine, phosphorus and sulphur and organic acids, and on five occasions I found estimable traces of stramonium, benzoic, succinic, and caproic. Most of these are claimed as candidates to sober reason: but up to date there is no proof

tive power, and any part of them—say, Calcutta's Or. Ol. shows at present's autopsies—is in itself or even operative in the vast proportion of the cases treated.

Many things that are physiological antidotes are not chemically so, and vice versa, and are frequently altered the physiological properties without changing the proportionate chemical constitution of the inorganic constituents of organic bodies; while a great deal depends on how the string is affected. Thus burned or unburned, the mineral and alkaloid constituents of the tobacco leaf which makes a Burmah cigar, remain the same; but in separate glasses of beer or potable spirits let us (a) steep a Burmah cigar for 2 hours, (b) throw in the ashes of a similar cigar that had been burned by smoking or (c) by inspiration, and note the physiological effects of any one of the above solutions on a human subject—(1) will nauseate him and produce the symptoms Mr RAM DHABI SIRHA quotes, (2) stupefies him and acts as a depressant narcotic but not as an emetic or diuretic and (3) first stimulates him to almost frenzy, then impairs the motor reflexes, after which it stupefies him and sinks him into a slumber from which it is harder to awaken him than from the sleep evoked by (b), unlike which nausea and purging, but neither emesis nor diuresis are among its after effects.

Why this should be I cannot tell, but I know that it is so, and it is quite possible that *hookah* tobacco may have beneficial though inexplicable reactions on cobraic acid, which unfortunately for the supposition of *similia similibus curantur*, exhibits symptoms antecedently opposed to those of narcotin or nicotine poisoning, though tarry nico-narcotine will kill a full-blown cobra which cobra-venom will not do.

Through a close and pretty extensive acquaintance with the ways and habits of the deadly *NAJA TRIPUDIANS* I am rather sceptical of all the published cures, except immediate excision and red-hot iron application which have never failed when done in time. I would really like to see the tobacco ash cure of cobra-bite tested on a scientific basis, rejecting hypnotic evidences of a genuine bite.

Yours, &c., PHYSIOLOGICAL ALCHEMY

MILITARYISM AND DOCTORING. A STUDY FROM LIFE

TO THE EDITOR, "INDIAN MEDICAL RECORD"

SIR,—Will you kindly publish the following skit—*Scene I*—The verandah of a British hospital in India, Time 7 A.M., Assistant Surgeon on the right of a line of ward servants (all dressed to kill).

(Enter F. E.).—Surgeon? No! I beg pardon Major!!!

Assistant Surgeon.—Saluting in approved fashion (which by the way he has not been drilled to) "squad ahn!!!" (Forte) (deathlike rigidity of whole) Major walks down line and inspects.

Major.—"Make this man a prisoner" (a water-carrier) "he should not have a piece of soap in his hand at attention and ejaculation of his coat is dirty, his turban is not tied properly, and the towel has left some flecks on his shoulder."

Assistant Surgeon.—"Tum vith hai" takes over his belt and rebukes him "Improperly dressed at morning visit."

Surgeon.—"Liaman." Assistant Surgeon.—"Mushai guru." "Shun."

Scene II.—Ward of a British hospital in India, Time 7 A.M.

Assistant Surgeon.—On entrance of Medical Officer. "Major so and so! ahn!!" (Fortissimo).

Major to 1st patient, looking down the line of bed-cots. "Your cot is not dressed in line my man, what do you mean by it?" (Forte).

1st P. "very sorry Sir, beg'y pardon Sir, but I've got a bad sor"—

M. (interrupting) "That will do, no excuses" (To Assistant Surgeon)

"Make him a prisoner" (To As: S) "You should see to this now; you are responsible, this ward is not ready for my inspection (inspection forthwith) I won't speak again about it."

1st P (sotto voce) "I'll as to ax the Potecarry to see my sore foot"

Major to 2nd Patient "what is the matter with you?"

2nd P "Pains in my stummick sor."

M "Oh! colic, show me" (patient shows stomach) "where's your cholera belt,? why have'n't you got it on, you're improperly dressed my man" (To A. S.) "make him a prisoner" (admonishes A. S. again, and goes to 3rd P)

2nd P (despairingly) "Oh! lor! the pain" A. S. "Silence!"

M (To 3rd P.) "Why don't you stand properly to attention? Where are your boots? Got a bad leg and foot? Have you? No excuses sir! keep silence, see that you have your boots on next time, and stand to attention" "Mr X note this man's behaviour carefully"

M (To orderly of 4th P a bad case) why is not this man's boots in line? Where's his basin and his blacking brushes, been vomiting just now, has he, why did you not put the basin back in time for inspection? Kept the vomit did you, no business to, my inspection of the ward first. Mr. X change this orderly, he is no good, get a better man."

A. S "Yes Sir! this man sir (pointing to patient) seems to be developing Pneumonia, I heard a few dry crepitations on auscultation, and there is dulness over the right lung on percussion, will you examine him Sir?"

M. "Yes! where's the bhisty? Bhisty! (forte).

Tableau—no Bhisty!

M. (Furiously) "Mr. X where's the Bhisty?"

A. S. "You made a prisoner of him sir on coming to the ward and I will have to see the Senior Assistant Surgeon before I can replace him."

M. "Oh! no bhisty, I will report you sir" (goes off in a pet to report, returns furious, sees the other patients, finding military faults ad nauseam, leaves the ward.

TAMARANT?

Yours &c., JON.

LOGS - PRO

DR. J. H. ADAMS

The National Endowment for the Arts

Six.—The Medical Profession in India, and the British Empire, owes much to the fact that it has made for its bold, fearless and generous members, the recently gazetted medical and surgical professions in the Calcutta Medical College. The Bombay and Madras Colleges need showing up in the same way. If Medicine, Surgery, Obstetrics, Sanitation and the other allied sciences are to stand ably and suitably represented in the Indian Colleges, a system of competition must now be opened and honestly followed. Medical Education in India cannot be sacrificed to "Service" interests, especially when "Service" men will not "brush up" for their high privileges, expecting that the holy or unholy traditions of their service will suffice to give them prestige and even answer the purpose of a bogus "apostolic succession" of inherited or "spiritually" acquired professional fitness for academic promotion.

I hereby challenge the Government of India and the India Office of London to throw open the Professorships of the Medical Colleges of India and their Hospital appointments to competition in the open field of the medical profession both here and in Great Britain. If it does, it will find no dearth of excellent candidates. Close the doors of the I. M. S. to these posts and far better men, and what is more, "fit" men will be found in large numbers.

QUININE AND ABORTIONS

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I read in your journal dated 1 October last under the heading of 'Abortion due to quinine' that a lady in her 3rd month of pregnancy aborted after the 4th dose (3 gr.) of quinine administered by Assistant Surgeon Mr. BALANGA-
PET L.M.S., Chhetaripoor, Burdikhand.

As the fever did not yield to other remedies the long continued suffering of the patients induced me to resort to quinine in mild doses and to closely observe the effects. At first I began to give 2 grs. 3 times a day, and as no untoward symptoms appeared even after 4 or 5 days of administration I was tempted to increase the dose, more than 100 cases have been treated within the last 2 years and not a single abortion has occurred. When some patients complained to me of pain in the loins and in the uterine region, in the course of quinine treatment, I need to give a little opium mixed with quinine. No doubt, medical men should carefully examine, before giving quinine, whether the patient has been taken ill before while carrying, and if so whether any bad effect had taken place and whether else it carried a tendency to abortion. Particular attention should be paid to the state of the bowels.

YOUNG REPUBLICAN LEAGUE

YOUNG & CO., GENERAL PRACTITIONERS 40, E.C. LONDON.
BOMBAY, November 1898.

THE CASE, "INDIAN MEDICAL RECORD."

On the 15th inst. of Oct. 1901, I saw a case from Amoy, a pregnant woman in which she described a case of abortion from quinine in 3 grains dose. Again I see in *Indian Medical Record* and art of midwifery, page 365, the *Indian Medical Record* in large doses for malarial fever and pregnancy. Recently two cases have come under my observation in which both women aborted after five and eight days, respectively, of Benittent fever. Neither of them had taken any quinine as they were both native women and objected to taking quinine.

Is it not probable that the abortion was due to some other cause?

It is hard to see how eight grains of quinine, given in two grain doses at intervals of 6 hours could produce such effect. There always been accustomed to give quinine in moderate doses to pregnant women, and so far I have not seen any serious results. However I have not tried it in this country. Probably the tropical climate has something to do with it. I would like to hear from others on the question.

Yours &c., W. W. ASHE M.D.

(We do not believe that quinine produces abortion. It certainly help uterine contractions when once they have started.—Ed., I.M.R.)

TREATMENT OF PLAGUE CASES.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Patients suffering from plague generally do well, if kept in open houses with free ventilation, which shows that pure air, containing a fair amount of oxygen, is beneficial for them. I beg therefore to request those having plague cases under their care to give the following plan of treatment a fair trial.

1. Oxygen gas to be inhaled at short intervals.
2. Internal use of oxygenated water, permanganate of potash, chlorate of potash etc., in small doses frequently repeated.
3. The buboes to be injected with permanganate of potash and antiseptic applications to be applied 3 or 4 times a day, (campher 25 parts, crystallized carbolic acid 9 parts and alcohol 1 part.) This to be diluted with olive oil for local application.

Yours &c., M. C. MUKERJI, L.M.S.

Book Reviews & Medical Trade Notices

ESSENTIALS OF MODERN TREATMENT OF DISEASE (PART I).

By K. M. NADKARNI, F.R.S.L. and A. (London).

Associate Editor, *Indian Medical-Chirurgical Review*, &c., &c.

(Publishers: H. K. Rao, and Co., Madras; Baillière, Tindall and Cox, London, Pages 312).

In this book, written on Therapeutics the practitioner is provided with a pocket compendium containing the outlines of the various methods of treatment and cure

recommended by various medical authorities. The alphabetical arrangement followed with reference to each disease will be found exceedingly useful. It is evident that the current literature of the subject scattered through various medical works and journals has been carefully collected in this hand-book under review. We shall look forward with pleasure to the appearance of Part II.

LEFT PALATE; TREATMENT OF SIMPLE FRACTURES BY OPERATION; DISEASES OF JOINTS; ANTREOTOMY; HERNIA, &c., &c.

By W. ARBUTHNOT LANE, M.D.

(Publishers: The Medical Publishing Co., Ltd., London. Pages 278. Price 5s.)

THIS work comprises a series of eleven Clinical Lectures which are certain to prove of no little use to the profession. Some skiagrams and photographic reproductions have been added to illustrate the text. The unique get up of the volume, in its white canvas binding &c., is quite a model of neatness.

HERNIA: PALLIATIVE AND RADICAL TREATMENT IN ADULTS, CHILDREN AND INFANTS.

By T. A. MANLEY, M.A., M.D.,

Surgeon to Harlem Hospital, U. S. A., &c., &c.

(Publishers: The Medical Press Co., Limited, Philadelphia, Pages 331).

IN view of the position now attained by the study and treatment of Hernia, Dr. Manley has succeeded not merely in ascribing to each therapeutic resource its due merit, but in clearly defining the limitations of each. The indiscriminate application of the truss in childhood is shown to be quite as harmful as too much operating in the case of adults, if not more so. In addition to the index the value of the treatise is enhanced by a Table of operations for strangulated Hernia and a Bibliography of works on the subject.

STEARNS' KASAGRA IN GOUT.

As stated by Prof. H. A. HARR, of the Jefferson Medical College, in the gouty individual the liquids of the body may be said to be so over-laden with salts that they deposit them wherever a spot is found which is easy of access, just as water laden with lime forms a deposit on the side of its bed when a drought comes on, and dissolves and removes these formations when a freshet takes place. For this reason he recommends pure water as a therapeutic agent to be used in large amounts and drugs which eliminate these salts, such as colchicum, etc. If the bowels are kept in active condition by Kasagra in such cases the elimination of the products which cause gout will be accelerated. The same authority recommends arsenic in subacute or chronic gout and when arthritis is present arsenic is particularly indicated; also cod liver oil, and syrup of the iodide of iron. Stearns' Kasagra is an excellent vehicle for the administration of Fowler's Solution.

EFFICACIOUS GERMAN PREPARATIONS

**PAIN-EXPELLER VOM: PAIN-EXPELLER & Co.,
Halle, Germany.**

Well known before last, according to notice the most recent preparations of this house. The intestinal astringent known as Tannin has been employed with conspicuous success in cholera and various other forms of Diarrhoea. Astringent, which is used along with Picro Acid most efficaciously in treating fevers and acids, is a fine red powder composed of Iodide, Iodide of Potash and Thymol. Its superiority to Iodoform lies in its being without the latter's irritating character and odour. The use of the Picro Acid not only lessens the pain of the burn, but its strong antiseptic properties limit the tendency to suppuration and induce rapid healing. TRONAL is a hypnotic drug as prompt as it is efficacious; as a sedative its action is highly satisfactory, inasmuch as refreshing rest is afforded to patients afflicted with insomnia without evil effects of any kind following its use.

Government Medical Gazettes.

GOVERNMENT OF INDIA.

The services of Asst. Surgn. J. T. Weston are replaced at the disposal of the Govt. of the Punjab.

The services of Asst. Surgn. John Robertson (Bengal) are placed at the disposal of the Chief Commr. C. P.

Asst. Surgn. and Hon. Lieut. Caesar Augustus Hellein to be Senior Asst. Surgn. with hon. rank of Captain.

Asst. Surgn. and Hon. Capt. Samuel Charles White is absorbed in the rank of Senior Asst. Surgn. with rank of Lieut.

Asst. Surgn. Joseph Wilcox Williamson to be first-class Asst. Surgn.

Third-class Asst. Surgn. John O'Leary to be second-class Asst. Surgn. from 26th June 1898.

Hosp. Asst. Mahboob Alam was apptd. a 3rd class Hosp. Asst. for Gylt. service and placed on the Native States Reserve List, hosp. asst. from 8th May 1898.

Medical pupils Sham Nardin and Bishen Lal Dube were apptd. 3rd class from 1st May 1898.

Hosp. Asst. Baghunath, Oodeypore Jail Hosp. died 22nd April, 1898.

Hosp. Asst. Ashgarali Khan, Tonk Dispy. privilege leave for three months from 21st July 1898.

Hosp. Asst. Haqarain, Abu Charitable Dispy. privilege leave for one month from 8th Aug. 1898.

Hosp. Asst. Chandra Singh, Beaudancy Hosp. Oodeypore, privilege leave for three months from 4th Aug. 1898.

Hosp. Asst. Nand Kishore, Palace Dispy. Bikanir, permitted to resign the service of Govt. from 18th Aug. 1898.

Hosp. Asst. Shif Ditta, City Hosp. Kotah, was promoted to 1st class from 15th April, 1898.

Hosp. Asst. Ram Farhad Baborji, Northern India Salt Revenue Dispy. at Bhatki, was promoted to the second class from 24th Dec. 1897.

Hosp. Asst. Sheikh Fasilul Hameed, Sreen Dispy. Maywar, to second class from 15th April.

Hosp. Asst. Maji Ram, Nohar Dispy. Sirmur, is entitled to draw the usual allowance for English Qual. from 15th April.

BENGAL GOVERNMENT.

Lieut. Col. R. Cobb, M.D., I.A.M.S., has been granted an extension of furlough for three months.

Capt. K. B. Barnett R.A.M.C., M.D., has medical charge of Dinapur from 26th Sept. 1898.

Col. J. Lawton, M.D., I.M.S., Civil Surgn. of Burdwan, leave for ninety days, from 1st Dec. 1898.

Capt. C. B. Stevens M.D., L.M.S., Resident Medical Officer, Med. Coll. Hosp. Calcutta, to act as Civil Surgn. at Burdwan. Asst. Surgn. Kali Mohan Sen, doing duty Pres. Gen. Hosp. apptd. as Resident Med. Officer, Police Hosp. Calcutta, to do duty at the Pres. Gen. Hosp.

Asst. Surgn. Benode Behary Ghosal is allowed leave for three months.

Asst. Surgn. Jognewar Mukerjee held med. charge Tangail subdiv. from 30th Sept. to 6th Oct. 1898.

PUNJAB GOVERNMENT.

Hosp. Asst. Abdulla Khan, Kalis Dispy. Jhelum Dist. having passed the English Qual. is entitled to the higher rate of pay from 18th Sept. 1898.

Hosp. Asst. Lal Chand to Karianwala, Gujrat Dist., 30th Sept. 1898.

Hosp. Asst. Alam Shah, Miran Shah Dispy. Tochi Valley, three months privilege leave.

Hosp. Asst. Ganda Ram, Jalaipur Dispy. Gujrat Dist. 90 days' privilege leave, 22nd Sept. 1898.

Hosp. Asst. Kamal-ud-din, doing genl. duty at Jullundar, to sub med. charge, Civil and Police Hosps., 26th Aug 1898.

Asst. Surgn. Diwan Ali, resumed charge Pindigheb Dispy. Rawalpindi Dist., 20th Sept. 1898.

Hosp. Asst. Goverdhan Das, Rawalpindi Civil Hosp., 23rd Sept 1898.

Asst. Surgns Lala Chaman Lal, Ram Chand, Mungh Arghar Ali and Thakur Kidar Nath were apptd to do genl. duty Mayo Hosp. Lahore.

Hosp. Asst. Ghulam Nabi, Civil Hosp. Hoshiarpur to Hariana Dispy. 10th Oct. 1898.

Hosp. Asst. Karm Chand, from Garhshankar Dispy. 23rd Oct. 1898.

Hosp. Asst. Gopal Das to do genl. duty Egerton Hosp. Peshawar, from 26th Oct. 1898.

Hosp. Asst. Bageshar Das, Dabwali Dispy. Hissar Dist. assumed charge Banis Dispy. in that dist. 14th Oct. 1898.

Asst. Saiful Rahman reported himself to the Civil Surgn. Jullundar, for genl. duty Civil Hosp. 16th Oct. 1898.

Hosp. Asst. Saiful Rahman, to Ruksa Kalal Dispy. 17th Oct. 1898.

Hosp. Asst. Abdul Rashid, Plague Inspection Post, Beas Amritsar Dist. having passed the English qual. exam. is entitled to the higher rate of the pay of his grade from 1st Nov. 1898.

Hosp. Asst. Maha Narain, doing genl. duty Civil Hosp. Hoshiarpur, privilege leave for 11 days, from 18th to 26th Oct. 1898.

Hosp. Asst. Harbans Singh, Civil Hosp. Ferozepore, having passed the English qual. exam. entitled to the higher rate of the pay of his grade from 26th Oct. 1898.

Hosp. Asst. Sahadat Ali, Sayadwala Dispy. Montgomery Dist. three month's privilege leave, from 15th Oct. 1898.

CENTRAL PROVINCES GOVERNMENT.

Hosp. Asst. Surji Rao, doing duty under Officer in Civil med. charge, Damoh, to Central Jail Hosp., Raipur.

Hosp. Asst. Surji Farhad, Raipur, Central Jail Hosp. Raipur, three months privilege leave.

Hosp. Asst. Khondal, assumed charge Civil Surgn. of Falam, Chin Hills, 25th Sept. 1898.

Hosp. Asst. Abdul Rasak, Kuru, to do duty under Civil Surgn. at Nagpur.

Hosp. Asst. Girma Nagt, Hende Branch Disp. Nagpur, to do duty under Civil Surgn. Nagpur.

Hosp. Asst. Sayid Abdul Aziz, Civil Station Disp. Nagpur, three months' privilege leave.

Hosp. Asst. Pandurang Lakshman, to do duty under Officer in Civil med. charge, Bhandara.

Hosp. Asst. Ramkrishna Appaji, Murwara Branch Disp. Jabulpore Dist. three months' privilege leave.

Hosp. Asst. Beni Parahad, to Murwara Branch Disp.

Hosp. Asst. Ramkrishna Palkaji, to do plague inspection duty at Itarsi.

N.-W. P. AND OUDE GOVERNMENT.

Asst. Surgn. Balhbader Singh, on Reserve duty, Agra, to Plague duty, Muttra, from 14th Oct. 1898.

Asst. Surgn. Baij Nath Vias, on reserve duty, Agra, to Plague duty from 13th Oct. 1898.

Asst. Surgn. Rup Kishore Tandan, M.B., and C.M., Hussainabad Disp. Lucknow, to Plague duty from 15th Oct. 1898.

Hosp. Asst. Sri Ram, on Reserve duty at Etawah, to Hussainabad Disp. Lucknow.

Asst. Surgn. Dalip Singh Katwal, Sadar Disp. Etah, to be Travelling Med. Insp. of Plague, Allahabad Circle.

Hosp. Asst. Abdul Hakim Branch Disp. Jalesar to Sadar Disp. Etah.

Asst. Surgn. Hari Ram Verma, Impl. Estab. Haldwani Disp. Naini Tal to Plague duty from 15th Oct. 1898.

Hosp. Asst. Rama Nand, Reserve duty Shahjahanpur, to Sadar Disp. Bara Banki.

BURMA GOVERNMENT.

Hosp. Asst. Maung Tun U assumed charge Civil Hosp. Pakokku, 12th Sept. 1898.

Hosp. Asst. Maung Aung Pru, three months' privilege leave, 12th Sept. 1898.

Hosp. Asst. Jeet Singh, assumed charge Civil Hosp., Maitimu Sagaing dist., 14th Sept. 1898.

Capt. F. J. Dewes, I.M.S., made over, and Major E. P. Frenchman, I.M.S., assumed charge Civil Surgn. Bassein dist. 15th Oct. 1898.

Mr. J. A. Maddox, and made over, and Asst. Surgn. Maung Thin assumed, charge Civil Surgn. Kyaukpyn dist. 17th Oct. 1898.

Capt. T. W. Stewart, I.M.S., assumed charge Civil Surgn. Akyab dist. 12th Oct. 1898.

Hosp. Asst. B. B. L. Agnihotry assumed charge additional duties Jail Hosp. Hemsada, 17th Oct. 1898.

Hosp. Asst. T. S. Melchisedech, transferred to Mandalay, 17th Oct. 1898.

Hosp. Asst. Josiah Maselamony relinquished charge additional duties Disp. Zigon, Tharrawaddy dist. 14th Oct. 1898.

Hosp. Asst. Moung Pa Myin assumed charge Mil. Police Hosp. Kinkat, Upper Chinwin dist. 14th Oct. 1898.

Hosp. Asst. L. J. Govindaswamy Pillay assumed charge Police Hosp. Maba, Chin Hills, 25th Sept. 1898.

Hosp. Asst. Shakti Abdul Aziz relinquished charge additional duties Civil Hosp. Falam, Chin Hills, 12th Sept. 1898.

Hosp. Asst. Sept. Chian, assumed charge Police Hosp. Falam, Chin Hills, 25th Sept. 1898.

Hosp. Asst. L. J. Govindaswamy Pillay assumed charge additional duties Civil Hosp. Maba, Chin Hills, 25th Sept. 1898.

ASSAM GOVERNMENT.

Leave for three months, is granted to Hosp. Asst. Sasi Kanta Sen.

Hosp. Asst. Gunabhi Ram Das was employed as a Supery. for duty under Civil Med. Officer. Nowgong. from 21st to 27th Sept. 1898.

Hosp. Asst. Sreedhar Barua, Lungleh Military Police Hosp. to Lungleh subdv. from 1st Oct. 1898.

Hosp. Asst. Jamini Kumar Ghose, to a Supery. for duty under the Civil Surgn. Sibnagar, from 7th Oct. 1898.

Hosp. Asst. Rajani Kanta Manlik, Supery. for duty under Civil Surgn. from 11th Oct. 1898.

Hosp. Asst. Ananda Kumar Bhattacharyya, has passed the English Qual. Exam. 15th Oct. 1898.

Hosp. Asst. Abdul Aziz, a Supery. Darrang dist. to Naga Hills dist. from 16th Oct. 1898.

Hosp. Asst. Jay Chandra Sukia, Hensma Mil. Police out post Naga Hills dist. to the Wokha Disp. 16th Oct. 1898.

Hosp. Asst. Abdul Gofur, a Supery. Nowgong dist. Pathari Disp. from 15th Oct. 1898.

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Rs. 1 for subscribers and Rs. 2 for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTHS.

HOWELL.—On the 8th October, at Upper Colaba, Bombay, the wife of Captain H. A. L. Howell, R.A.M.C., of a son.

CONDON.—On the 1st November, 1898, at Rock View, Chakrata, the wife of Captain E. H. Condon, R. A. M. C., of a daughter.

MARRIAGE.

MACPHAIL—WELLS.—On the 14th October, 1898, at Pol. Lokshields Free Church, Glasgow, by the Rev. W. M. Macphail, M.A., Streatham, London, brother of the bridegroom, assisted by the Rev. J. Hood Wilson, D.D., and the Rev. J. M. Sloan, M.A., Edinburgh, Janet Russell Wells, L.B.O.P. and S., eldest daughter of Rev. James Wells, D.D., Pollokshields, to the Rev. James M. Macphail, M.A., M.D., Free Church Mission, Chakal, Bengal.

DEATH.

BING.—On the 16th October, 1898, at Rawalpindi, from the effects of illness contracted on service in the Tirah Campaign, Lieutenant-Colonel James Bing, Royal Army Medical Corps. (Deeply regretted by all who knew him).

THE CONFERENCE IN ALLAHABAD

Dr. J. C. (Allahabad).—The matter is too important to pass over without being mentioned. The subject concerned is the subject of the hour.

Dr. J. C. (Allahabad).—Do not expect papers but do not give the same, though he says that his papers be returned after perusal. Will be the good enough to once again state his name and give his name and address.

Assistant Surgeon (Ferozepore G. F.).—We have written to him about your case.

Dr. J. C. (Allahabad).—We note the fatal case of abdominal aneurysm in chronic bowel trouble in a European lady. We note also the want of attendance of the resident and visiting officers.

A. A. (Bangalore).—Many thanks.

General Hospital Assistant.—Too late for this issue.

M. (Allahabad).—It is something new to learn that some public paralytics is to be treated by rubbing aniline balsam into the painful part. We note the outdoor dispensary ticket No. 8256 of 4th October.

P. M. (Calcutta).—We note your statement that Mr. Price the Head Clerk of the Inspector-General of Civil Hospitals, Bengal, is a Eurasian and the stepson of a Mr. R. T. Hanby who used to be Inspector of the Customs Preventive Service in Calcutta. We note also that he was appointed in place of Mr. White, when the office, to which Mr. Price was attached, was amalgamated with that of the Inspector-General. We note also your statement concerning other details.

R. G. C. (Calcutta).—We note your statement that Drs. Warden, McConnell, King, Whitcombe, Dracup and McKenna were all Anglo-Indians, and were members of the I.M.S. We note also your statement that they were your relatives.

T. C. (Allahabad).—The Conference in Allahabad will it is hoped do much good. The Mexican colonisation scheme was published in the daily papers by ourselves.

P. M. O. (Calcutta).—We have received numerous statements about these scoundrels. We mean to place the whole matter before the authorities, and if they are not punished administratively we shall move the solicitors of the Indian Medical Association to take criminal action against those against whom we have convicting evidence.

Jack.—Your petition in Urdu must be translated into English before we can do anything with it.

W. C. (Wadi Junction).—Get a copy of the "Medical Register and Directory of the Indian Empire" where you will get all the information you require. We shall be glad to help you with letters.

Military Hospital Assistant.—Every member of your service, whether Civil or Military, should immediately join the Indian Medical Association and having done so they will be entitled to the support of its Council.

P. M. O. (Bombay).—We are perfectly willing to take any action you may wish to take.

Indian Army Nursing Officer (Bombay).—Write to the Under-Secretary of State for India, Whitehall, London, and you will obtain the information you require.

A. R. A. (Mekran).—Thanks for the opportunity. We shall use them as opportunity offers.

An old Assistant Surgeon.—We think the matter will better drop.

W. H. F. (Bombay).—Your remarks are very appropriate about P. M. O.'s Head Clerks. Our note elsewhere will show that we are in possession of damning evidence against these harpies. We wish more men in the service would send us still further proofs. There will be no response of the writers. We wish to put an end to this evil system of blood sucking.

A. D. M. (Ferozepore).—Many thanks for your paper. It will appear in due course.

The Weekly Record.—It is most satisfactory to see so many subscribers signing their post-card sentences for the *Weekly Record*. A few Hospital Assistants have written stating that one rupee a month for a weekly paper is more than they can afford. We are sorry to learn that the graded subscriptions should fall heavily on anyone's pocket. One rupee a month and one rupee and eight annas a month are surely small enough prices, and no Hospital Assistant or Assistant Surgeon ought to feel this hard. The rates unfortunately cannot be lowered.

R. D. G. (Calcutta Medical School).—We agree with you that the classes and the instruction in your school and in the Campbell Medical School are about on the same level.

Local Practitioner. (Hyderabad, Sindh).—Complais of the veterinary surgeon "practising medicine of human subjects." If our correspondent will sign his name to his letter (not for publication), we shall publish his grievance.

M. G. (Islampur).—The Surgeon General with the Government of Bombay is an ardent reader of the *Record*. Almost every I. M. S. officer reads it.

ANTIPYRIN FOR DIAGNOSTICATING SICKLY DISEASES.

Dr. L. BREMER, in a paper read before the St. Louis Medical Society, has expressed the belief that he has discovered a new method of diagnosing diabetic, pancreatic and kidney diseases by means of the affinity of the blood and secretion of a diabetic patient for certain aniline dyes. His experiments demonstrated that the secretion of a healthy person has an absolute antipathy for the dye known as ponceau violet. When the dye was poured into the secretion of a healthy person it remained floating upon the surface. When the same dye was poured into the diabetic urine it dissolved instantly and colored the whole mass. The secretion of the dye and urine upon the reaction, secretion was made manifest, showing the color and secretion of the dye was true, beginning with red and gradually passing into blue and white at the top. The color of the secretion was affected in the same manner in the same way.

concerning infants, children, & women. (Continued.)

Age and sex	Number per a. m.	Number per a. f.
Children (under 10)	201,000	151,000
Children (10-15)	20,000	20,000
Women (under 15)	20,000	20,000
Women (15-20)	20,000	20,000
Women (20-30)	20,000	20,000
Women (30-40)	20,000	20,000
Women (40-50)	20,000	20,000
Women (50-60)	20,000	20,000
Women (60-70)	20,000	20,000
Women (70-80)	20,000	20,000
Women (80-90)	20,000	20,000
Women (90-100)	20,000	20,000

We are obliged to conclude that individual animals hold; of their very nature, a "potential" energy which, becoming active and kipeic, repels the bacillary hosts; certain types of men and women may live with these in periodic, but will not—cannot in general—be subject to the phthisis bacillus, the Hindus and Moslems of Bengal do not, in the main, fall victims to the epidemic bacillus during the S. W. monsoon; but they pass into cholera rates, with the extremes of their climate, the great heats of April and the coldest season in December.

Thus, whether we contemplate disease, naturally or historically, the mind is carried into far wider circles than those of the sterilisation of water or of milk. At the same time we all bow with respect to those exact researches on water and milk which have shown us one assured and safe but partial path into the great field of zymotic disease.

In chemistry, physics, astronomy,—i.e., in the exacter and more elementary sciences—one fact, often exceedingly slight, if pursued, opens up the widest general truths and even universal laws. But such instances, as the established facts, that typhoid, scarlet fever, &c., have been carried by water and milk do not imply universal laws, and for the reason that the organic cell and organic life are absolutely cosmic in their correlations and evolution.

Necessarily, in a large dispensary practice, amongst the poor, I have seen great numbers of children with chronic diarrhoea. There are a great variety of admirable diets within our reach, but I have, during forty years, been continually reminded of and impressed with the neglect of the use of "acid fruits" in the chronic diarrhoea of children, from one year old upwards. In India the young and old will beseech that they may have tamarind, lime-juice, sugarcane, &c. In my early experience I gave children and adults who had chronic diarrhoea, tamarind, lime-juice, &c., with great caution; I had been warned against their use by high medical officials, but the earnest demands of the people for these foods could not but arrest my attention, and I saw no just "philosophy" against their use. On the contrary, the diarrhoea and dysenteric-diarrhoea of the Native was not an affair mainly of the bowels, but had the widest generic basis of an anæmic, or semi-scorbutic and exhausted vitality, the result of many generations of hereditary poverty of food, and ages of climatic influences.

* Mr. J. Aitken in the Transactions of the Royal Society of Edinburgh, Vol. XXXV, part I, 1896, gives as the result of his experiments on "The number of these parasites in air."

† I was once associated on medical duty with a "barra Sahib" whose wife determined to have, for her own use, pure and good milk she therefore procured a milch goat, but it was remarkable and vexatious to the Barra Sahib that she could, even then, get no milk for her breakfast, Nanny was dry every morning. There was about the place a very pretty young English girl called Dick; her office was to drink the image of the goddess Durga, in the Temple with seven, she was also welcome to the village. One of my night watchmen reported to me that he had caught Dick lying on her back with her face under Nanny, sucking the stream from her mouth. A pleasant joke was all that could be extended to the beautiful and clever animal! She derived no harm from Mr. J. Aitken's germs or dust!

The prevalent "habit" of the Native of India, as related to, and in connection with, the chronic diarrhoea, was known to an irregular quotidian fever; thus the chronic diarrhoea in the native of India had to be viewed from the widest pathological stand-point, and his demand for "acid fruits" had to be deeply considered. I began my use of tamarind, lime-juice, &c., in the chronic diarrhoea of the native with great fear and anxiety, but I very soon saw that his craving for them was a just call of nature. I found that I could hardly err in the freedom with which I gave "acid fruits" to the chronic-diarrhoea-stricken native.

Native men, women, and children would come about me and ask for "nimboo ka arack" lime-juice; they would continually say:—"Sahib, my health will go right if I drink lime-juice." It was impossible to ignore the earnestness of the people; we have deeply to learn from the ages of the historic experience of the East. You see a semi-nude man or woman in the tropical early morning, going down to the Ganges to bathe and worship; they have no desire to be seen or approved; they walk down the muddy banks and enter the river. They perform their worship and function of health, return to the top of the bank, slip off their wet cloth for a dry one, and return to their village and duties. Such is the East; a wise and grand simplicity of life remains; the same simple earnestness and truth of life obtained when the great literature and Ideas of the East evolved, as written in the Vedas, the Psalms, Gospels, Epistles, &c. We can no more ignore the habits of Eastern people, in reference to health, than we can ignore their poetry and highest mental and spiritual philosophy. The splendour of a Lord Mayor's dinner, or of a Sunday morning's fashionable ladies' church-parade, are no doubt marks of a high civilisation here; the naked Hindu making Puga in the Ganges, unseen and unknown, expresses an equal if not a higher civilisation,—*"East is East, and West is West."*

Here, we have the glorious institution of the "morning press," "educating" the world! There, the greater phenomena of nature, the greater dangers to life, a less physical robustness, make men live in a more constant sense of dependence, and in a more subdued spirit. The Native sitting on the bank of the Ganges can hardly feel interested in the last ephemeral publication of the *Strand*, or in the latest fashion of bonnets, dresses, collars, &c.

Now, what I have tried to convey as to civilisation in general, has its application in medical practice; your fever-saturated, dysenteric, diarrhoea-stricken, anæmic Native will often be treated in vain with the best drugs, —oupi S, plumb. acet., bismuth, chalk, catechu, haai, &c., &c.,—and even with the grand old medicine—opium; the native man or woman with chronic bowel complaint, having a dozen motions daily, will ask for lime-juice; his instinct is a safer guide than is our Western teaching. There is not only no risk in giving lime-juice, but the patients will often recover under its use. I never ignored the valuable drugs I have named, or any other drugs, but I had to submit my Western home and "school" teachings to the greater "light of the East."

Similarly with Natives, in chronic diarrhoea, the fever taint must ever be kept in view, and quinine in large doses demanded.

...the most perfect of the philosophy of the East, and the most recent I have taken a glance at the most modern and our drugs, and rather outside current medical theories.

I submit that we in the West, notwithstanding the magnificent labours of exact science, have still much to learn from the simple observation of the habits and experiences of ancient peoples and their civilisation.

I have long learnt to apply some Eastern experiences to Western people, e.g., children with chronic diarrhoea often will drive for a little vinegar, lime-juice, pickles, &c., with their food. I have very rarely, if ever, as far as I can now remember, had reason to regret ordering such in suitable cases; but I have continually seen good from their use.

But it is not only in chronic diarrhoea that "acid fruits" do good; they are of great use in that habit of body where the boy or girl has chronic eczema of the body, behind the ears, and scald-head. Such children are often most carefully dieted, debarred fruits, vinegar, pickles, &c. If such children tell me that they like apples, green gooseberries, pickles, &c., I not only do not debar them but encourage their use. I cannot remember that I ever knew a boy hurt by stuffing himself with green gooseberries, or raw apples, or aloe. Old East Indians are not hurt by a free use of turpentine-flavoured mango in its season. The negroes in the West Indies will make short work of two feet of ripe raw sugar cane.

From nations, north, south, east and west, adults and children have shewn the value of fruits and vegetable acids, and I would add my small testimony to their value and necessity often in the chronic diarrhoea of children in Britain.

At the end of last year—1897, a medical man told me of his child, aged about one-and-a-half-years, who was suddenly seized with profuse diarrhoea, and instantly with almost fatal collapse: brandy was given, and it rallied; but several fingers and toes mortified and came off, so nearly fatal was the collapse; the circulation must have ceased in the extremities, leading to the gangrene. The diarrhoea remained many days, in a less degree, highly fetid and severe. I suggested a teaspoonful of the juice of a lemon twice a day in water and over its food. The child at once improved and rapidly lost its offensive motions and got well.

I am not now referring to acute fevers or inflammations, but to chronic disease of varied types where the appetite

"The habits and practices of primitive races are founded on a vastly long experience, and are thus always worthy our best thought and study. Savaterra says (search in quest of Franklin's Records), that when the Esquimaux hunter has captured a seal—"the next operation is to make a slit in the stomach, of the sometimes still breathing animal, and to cut off some of the warm liver (lung-yeer), with a slice or two of blubber (che-cook), wherewith the hunter regales himself with a hearty luncheon." The same traveller says of walrus—"The largest part of an Inuit's food is, however, eaten raw." But the Esquimaux boil such food when possible, and that "O-yook, O-yook," is the cry for warm walrus meat; such "warm food" feeds as "fatal occasion, though they occur several times a day, and may happen at any hour of the day or night."

A most interesting and instructive account is given by Schwatka of the value of vegetables and fruits, he says—"As soon as the snow leaves the ground, the hill sides in many localities are covered with the vine that bears several black berry (called by the natives parwung) in appearance, though not in flavour, like the huckleberry. It has a pungent, spicy taste, and is very acceptable after a long diet of meat alone, and the natives when they find these vines stop every other pursuit for the blessed medicine of stimulating their stomach with the fruit. This is kept up if the crop only fails for a few days until they have made themselves thoroughly accustomed to the fruit. But the craving for some sort of vegetable diet is not satisfied with this small improvement; they indulge in various

foods, in such often I have found great benefit in departing from the overstimulating English cooking of mutton, beef, poultry, &c., and from giving the patients some of his unorthodox dishes, e.g., boiled crabs, fisher, or cray-fish, with plenty of malt vinegar; in other cases, salt-bath of various kinds is much relished. In cases of indigestion in some of its so-varied forms and wide bases of correlation—I have often seen the greatest benefit from giving the patient a rather free play in the matters of diet. In the over-feeding and over alcohol-drinking Europeans, a moderate use of Carlsbad or Frederickshall, &c., will do wonders, the activity of the whole organic tract seems to be roused by these waters. I have not hesitated to stop the use of tea; I find that some medical men, in nearly all cases of "indigestion," stop the unhappy patient's tea; I do not think this medical practice goes to the root of the matter; it is a narrow generalisation and practice to debar patients in general the moderate use of tea. Tea is made the scapegoat of many ailments.

As to potatoes, we all know how great is their value in preventing scorbutic dysenteric-diarrhoea. Dr. BALY's experience and researches, at Mill Bank Penitentiary, should be more known to the present race of practitioners; were this so, potatoes would not be so often debarred. I order them to be steamed or baked in their skins. It has often happened to me to find children loathing ordinary food, eat with avidity potatoes so prepared. Of course, a little butter and salt are used with them, and I have often found that children will greatly relish them with a dash of malt vinegar. I was once at St. Helena with 500 Natives of India. A Jersey Schooner arrived with a cargo of potatoes, having the legal right, I requisitioned 100 bags at £1 sterling a bag, but greatly to the disgust of the merchant firm which had to pay for them. I knew of BALY's great teachings, and I knew from my own experience the value of potatoes to the semi-scorbutic; a *fartore* in cooking them, they were washed only, previously. They were then cut up with their skins on, and carried for my people; as the Irishman saves all the juice, salts, and 'virtues' of the potato in his stew, so I saved these same in the liquid curry.

When the Native cuts up his potatoes (if he can get them) for his curry, he never skins them, he is far too intelligent to skin them and then boil away their salts, as is the fashion with ourselves. But if you would give the Native joy in his food he must have some lime-juice in his curry—"acid fruits"; a sure instinct and a vast experience has taught him this.

In a vast degree amongst the Natives of India, the so-called "different diseases" of our nomenclature blend and have innumerable gradations; a faithful observer will often be puzzled to say under which name he should group certain cases—whether as anæmia, or scorbutic, or fever (Bakar or Tap), or of the dysenteric-diarrhoea, or diarrhoea groups. The Native often has a cachexia with, I may say, a blend of all these "different diseases"; the greatest skill, experience, and pains, will often be at fault in judging the vital power of the Native. Seemingly the men will

* Dr. Baly says:—"Wherever this disease (scorbutic) has prevailed, there the diet of the prisoners, though often abundant in other respects, has contained no potatoes or only a very small quantity. In several prisons the occurrence of scurvy has wholly ceased on the addition of a few pounds of potatoes being made to the weekly dietary." (Wagon's Friends of Florida. Lecture, &c.)

the onion supplies the benzene molecule with its closed chains and molecular stability, to the feeble bonds of protoplasm both in the Native of India, and in the European.

But if this temporary hypothesis be unstable and ephemeral, yet it remains that a vast number of most delicate pre-phthical youths, girls, and adults have most emphatically stated their great desire for onions and the good they get from them; the empirical as of old, points the way, however weak may be our hypotheses, we can not too strongly hold the principles that phthisis is not a "disease" added to the system, is not, in its deeper nature, a disease "caused" by a bacillus, is not mainly "disease of the lungs," but that its foundations reach back to the blastoderm, and even in atavic phthisis to the blastoderm of remote—even very remote—ancestors, phthisis must be viewed in the light or method of "variation" in species, i.e., that the system or individual may be made to retain much of its type, or may be made modifiable by environment, by changing its conditions. In this view it is obvious that a fit and suitable food may have a powerful influence in sustaining the conditions of health in a prephthical subject. At any rate I have but to record my experience and observations, both in India and Europe, and to ask my brethren, either to support or demolish from their experience, my "Idols of the Den."

ARTHRITIS IN CHILDHOOD. ITS VARIETIES AND THEIR DIAGNOSIS*

By Gmo. F. STILL, M.A., M.D., M.R.C.P.

Medical Registrar and Pathologist to the Great Ormond Street Hospital for Sick Children, London.

SIMPLE, as seems this subject at first sight, the more one sees of the various forms of arthritis that occur in children, the more one is impressed with the difficulty of diagnosing one variety from another for prognosis and efficient treatment.

As much tenderness with swelling and redness of joints in a child always raises a suspicion of something else, it is not easy to diagnose the articular rheumatism of childhood where the severity of joint symptoms is quite the exception, but in children the following symptoms which are far commoner than in adults will materially assist the diagnosis—The presence of (1) a distinctly endocarditic

beat and (2) subcutaneous nodules, neither of which is to be looked upon as a clinical curiosity, but as a valuable aid to positive diagnosis.

A history of rheumatism in the family is of some value; but too much stress must not be laid on it as it is very common to get a family history of some rheumatism, where the child shows no rheumatic taint whatever.

When you see a baby with swellings about the joints, you can be pretty certain that it is not rheumatic; as there is practically no such thing as articular rheumatism in infancy.

Always inspect the child's gums and bear soury in mind when you are tempted to diagnose rheumatism in an infant, for there are few diseases that respond so rapidly to treatment or so closely simulate rheumatism as soury.

Epiphysitis, whether syphilitic or otherwise, has been mistaken for rheumatism; but the extreme local tenderness, the oedema extending beyond the joint, the severe general illness and the occurrence of suppuration in one or more of the affected joints speedily settle the diagnosis.

Except when there is a distinct history of syphilitic infection or it is concurrent with ophthalmia neonatorum, gonorrhoeal arthritis is very hard to diagnose, without bacteriological examination, though it does occur in infants as well as in older children, and last year Dr. Lums treated a girl, not 35 months who had a profuse purulent discharge from her vagina, while her hands and wrists were swollen and painful. On treating the vaginal discharge the tenderness of the hands disappeared quickly, but the swelling remained for some weeks.

The stiffness of the neck, tenderness and pain about the shoulders and some rise of temperature that mark the onset of infantile paralysis occasionally suggest the possibility of rheumatism.

Monarticular rheumatism is apt to be very puzzling in children, and the tendency to affection of the hip joint in the rheumatism of childhood has caused curious errors of diagnosis. Thus two children were admitted, the one for perityphlitis, the other for intussusception, because among other symptoms both children complained of pain in the right iliac fossa; but subsequent events proved the whole trouble was rheumatism of the right hip-joint.

Gouty arthritis does occur, though with extreme rarity, in childhood, and a few instances are on record where undoubted and severe hysteria simulated rheumatism in children under twelve years of age.

So much for acute rheumatism. Let us now discuss chronic fibrous rheumatism which is distinguished from the former by the inflammatory process extending outwards to the surrounding structures to produce adhesions and thickenings that enlarge and permanently fix the joint.

The diagnosis of this condition depends partly on the curious firm fibrous thickening about the joints and partly on endocarditis, subcutaneous nodules and other well-known rheumatic manifestations; but it is likely to be confused with the various forms of rheumatoid arthritis, of which two forms are usually seen in children.

The first of these is a progressive polyarthritis which begins, usually, before the second dentition and affecting almost every joint in the body produces effusions into the joint cavity, thickens the capsule, causes changes in the

*Presented before the Indian Medical Record at a lecture delivered at the Great Ormond Street Children's Hospital.

the first group. The acute form is characterised by the fact that there is an antecedent stage, the diagnosis and treatment of which is the first step in the treatment of the disease. The acute form is characterised by the fact that there is an antecedent stage, the diagnosis and treatment of which is the first step in the treatment of the disease. The acute form is characterised by the fact that there is an antecedent stage, the diagnosis and treatment of which is the first step in the treatment of the disease.

The second division of this vague group resembles the rheumatoid arthritis of adult life in all points. There is no enlargement of the spleen or other glands and no rheumatic complications though there are slow enlargement and stiffness of several joints and osteophytic changes with swelling of bone which settle the diagnosis. This form of the disease usually begins after the age of six years and can also be distinguished from tubercular disease by its extremely chronic course, the absence of other evidence of tubercle, the symmetry of the affection and the number of joints involved.

Though the two diseases overlap in their pathology and bacteriology, septic arthritis may clinically be classified as arthritis (1) with specific fevers and (2) with a primary focus of infection.

The arthritis that follows scarlet fever and diphtheria is not always a transient affair and seems to be most common after severe faucial affection; but the extreme constitutional disturbance, the exquisite tenderness of the joints and the presence of oedema over them are the determining points against rheumatism.

In most of the cases of arthritis following measles there is some severe lung complication which may be the source of the arthritis.

Influenza sometimes gives rise to a septic arthritis which occasionally follows mumps or may be the result of erysipelas.

Quite early in typhoid in children there sometimes occurs a transient arthritis which is indistinguishable from rheumatism till it reaches the suppurative stage; Yet there are cases where articular rheumatism, in a child, has given a temperature chart like that of typhoid.

In the second group the arthritis has its origin in some definite localised source of infection such as otitis media, empyema, bronchiectasis and syphilis.

In posterior basilar meningitis of infants there is sometimes a swelling about one or more joints which might be put down to arthritis; but if the swelling be cut down on, the joint will be found perfectly healthy while the lesion consists of a lymph like exudation about the tendon sheaths in the neighbourhood of the joint and round its capsule.

Tubercular arthritis, though at first somewhat confusing may be distinguished by the characteristic "pulpy" feeling of the joint, the evidence of the tuberculosis elsewhere and the course of the disease.

In septic arthritis due to any of the above causes the joint affection may be (1) quite a transient affair or (2) may result in permanent thickening and adhesions with any degree of fixation up to complete ankylosis of the joint or (3) there may be suppuration and complete disorganisation of the joint.

The above group having been considered, it remains to consider the group of septic arthritis which is characterised by the fact that there is a progressive increase in the number of joints which become swollen and painful, and which are not limited to the joints of the extremities. The history will usually reveal some of the following points which distinguish it from the rheumatoid arthritis, namely, that it is usually of a more rapid onset, that it is usually of a more symmetrical character, that it is usually of a more severe character, and that it is usually of a more chronic character.

THE MEDICAL INSPECTION OF SCHOOLS*

BY DORA KACH.

President of the Committee on Medical Inspection of Schools of the Public Education Association of Philadelphia.

In October 1896, their Sanitary Superintendent, Dr. CHARLES F. ROBERTS told the New York City Board of Health that the best way to avoid the contagious and infectious diseases children frequently transmitted to their schoolmates, was to make a daily systematic examination of the school children by medical inspectors of the Health Departments.

The 'Parochial Schools' of Philadelphia did do this long ago, but gave it up owing to a mistaken and ill-founded opposition, which however, opened the way for the Boston Health Board to conduct preliminary investigations into the scarlet fever and diphtheria records of the 19 years immediately preceding 1890. They found that the smallest number of cases occurred during the summer vacations and the largest in January. Thus, these 19 years shewed.

	Diphtheria.	Scarlet fever.
January ...	3,339	3,107
June ...	2,537	1,835
August ...	1,765	1,393

The Boston Board immediately recommended daily medical inspection of school children; but it was not till 1894, when a severe epidemic of diphtheria forced them to it, that they inaugurated the work as a city health-protective measure with such grand results that Chicago followed suit in 1896 and New York in 1897, though Philadelphia adopted the system in the Girl's High School in 1892. Then Brussels took up the strain which spread to Europe on the Boston plan and now Providence, Baltimore and Milwaukee are seriously agitating the question which is the key-note to progress.

But it was not till November 1896 that New York acted upon Dr. CHARLES F. ROBERTS' warning by securing the absence list of a class in which a case of contagious disease had occurred and visiting the absent children to learn the causes of absence. The examiner reported that though every severe epidemic had come from abroad, many cases of diphtheria and scarlet fever were introduced, while children sent home by teachers for "sore throat" frequently failed to call in a physician but returned to school when feeling well, even though at times they were in just the condition to spread contagion and should have been quarantined.

* Health Report, made by the Sanitary Superintendent, Dr. Charles F. Roberts, to the New York City Board of Health, October 1896, and published in the New York City Health Report, November 1896.

inspector should be a person of the highest character, a man of high moral and intellectual standing, and one who is not only a physician but also a teacher. His work is to examine the pupils at the opening of the school, to examine all pupils found ill or complaining of any disease, and to see that the system should be kept in the best condition. (4) exclude contagious diseases from the school. (5) his diagnosis &c., in a book kept by the Principal and forwards daily or weekly reports to his chief.

When practiced systematically, every day, inspection takes up but little time and causes but little confusion and that a great deal of good is proved by the facts.

(1). Out of 3,964 pupils examined during 1896 in Boston, 1,156 were too ill to remain in school, 3,994 had oral and respiratory affections and 267 specific infectious diseases; while in one school parasitic diseases of the head showed 74 per cent. affected and 7 per cent. badly affected.

(2). During the last four months of 1896 the inspections revealed 1,417 cases of diphtheria and 306 of scarlet fever at Chicago, where, however, in the school year 1896-97 as many as 4,028 infectious cases were detected.

(3). In New York 702 cases of contagious eye diseases, 2627 of parasitic diseases of the head and 804 cases of other contagious diseases were found in 63,812 children examined in the first three months.

As far back as 1878 Dr. S. D. RISLEY started an enquiry into the eyesight of pupils at Philadelphia and later on wrote "many a school-boy idle only at his books, dull only in the recitation room, is so because he finds the continued use of his eyes a painful task" and near-sightedness necessarily affects his mental and physical constitution, and a system of education that attempts to force the same results from all children alike, often mistakes the means for the end by keeping in view the system rather than the child's development; but as Dr. RANDALL puts it, "It would certainly be an incubus to the teacher to constitute an official group of lame ducks for whom forward seats, special illumination or lightened burdens are required." Still the facts remain that of 2,000 children examined on behalf of the "Philadelphia Teacher's Society for Child Study" 54 per cent. had defective vision though in the majority of the cases the affected pupils were not aware of their affection.

In America near-sightedness rises from 4.5 per cent. of children 3-5 years of age to nearly 20 per cent. at 17-5 years old, and as even perfect hygienic conditions of hours, seating and light failed to arrest the increase of near-sight in Germany. The committee of the County Medical Society (Philadelphia) have drawn the conclusions that—(1) the possible presence of defective vision should be excluded by examination before entering school; (2) the course of study should be so chosen as to avoid protracted use of the eyes at a near point, while (3) every examination should be done away with and (4) text-books should be printed in large type on good paper; but (5) the method of writing should be improved. (6) That as numbers of pupils grow up, they should be kept out after the first few years

a more healthful condition of the child should be secured by the provision of better food, and by the introduction of a more systematic and regular system of exercise. (7) The medical inspection will find a useful line of duty in the incidental detection of defective children, since the modern view of individualism in education seeks to adapt conditions to the child and the child to conditions.

Last July, Mr. ALFRED GRANT, Superintendent of the city of Chicago, reported to the Board of Education a plan for the creation of special schools for the deaf, blind, small numbers and confined at convenient points. Chicago reports eight such public day-schools. Europe has special schools for special classes and a few such already exist in Boston, Chicago, Providence and Wisconsin; but though an intelligent public may recognize that facilitated work and results to both pupil and teacher, justify a demand for special schools for the mental, the physical and the moral defectives; still to be thorough the work should include private schools, kindergarten classes, day schools, and day-nurseries quite as much as the public and parochial schools and the financial basis of such medical inspection must be thought of, since an average of 1000 pupils and 3 school houses constitute the capacity of work for each inspector. Boston maintains 60 and New York 150 Medical School Inspectors at an annual cost of \$10,000 and \$45,000, respectively, irrespective of report-blanks, office-work and incidentals.

Medical inspection should begin in the kindergartens and primary grades which practically include all children under 10 years of age; but the former demand the closer scrutiny, since, in them, by virtue of different processes, children are brought into close contact with each other, and use in common a large number of objects liable to become infected. Apart from other institutions and older children Philadelphia has 395 school-buildings where 113, 277 pupils below grammar grades, study, and to do justice by these children at least 113 medical inspectors will be required.

In Chicago the inspection had to begin in the old school houses, since the number of sick children from the old are greater than from the new buildings in which more attention has been paid to hygienic considerations.

It has been estimated that 7 per cent. of epidemics might be prevented by efficient school inspection; and the Boston pioneer in school work, Dr. S. H. DRAPER, writes "while not attracting any special attention, a child with unrecognised diphtheria (for instance) may yet attach infective matter to the desk, chair, slate, books, slate or lead pencil, penholder, sponge, drinking-cup, door-knob, door, window-sill, radiator, vases, etc., or to anything else which he may handle or touch after using his fingers about his mouth, and the fact that these things may become infected with diphtheria in this way has been conclusively shown in the laboratory by Professor HERTZ."

Attention should also be directed towards overcrowding, heating, plumbing and ventilation, dark classrooms, insufficient and uncleanly lavatories, seating and school furniture, recess periods, over-study and grading of pupils.

Again there are many diseases for which the law requires no report viz. parasitic diseases of the head, contagious eye-diseases, follicular tonsillitis and oral and nasal

the medical profession quite generally, through the press, has suggested or endorsed the movement for canal inspection, which comes properly within the function of City Health Boards, yet no less does it claim the interest of physicians and teachers, and wherever established Boards of Education have co-operated in the work.

BUCKINGHAM CANAL AND INCREASE OF ELEPHANTIASIS AT MYLAPORE IN THE CITY OF MADRAS.

By JAMES HARRIS, L.M.S.

Madras.

Or late there has been a universal impression among the Mylaporeans that there is just at present a considerable increase in cases of elephantiasis in their midst. This alleged increase has also been attributed to the Buckingham canal which runs through their midst. This view being confirmed by two medical men one morning by simple ocular survey, I bear a continuous agitation is kept up for the abolition of the canal. In this particular case I cannot concur with them (as to the guilt of the canal), as I fully believe, as I have attempted to show below, that the Buckingham canal does not bear on its head half so many sins as the innocent witch that is frequently murdered for having brought misfortune on the kingdom, family or person of an African Potentate. Let us carefully study whether the canal could be blamed as the originator or aggravator of elephantiasis, of course granting there is really an increase of elephantiasis. Every resident in Madras knows there had been cases in the city long before the canal or its originator was heard of. It is being emphatically asserted that elephantiasis was unknown at Barbadoes before the advent of an individual suffering from elephantiasis, and Dr. BANCROFT a great researcher and author believes that the disease has been introduced in Queensland by Chinese coolies from Amoy; our duty here therefore is not to discover the original cause as it already exists in elephantoid patients, but to disclose the vehicles of inoculation from the original cause on the intermediary host as it is aptly called.

Thanks to the indefatigable researches of Dr. MANSON and his colleagues, who have proved beyond doubt that the mosquito is this intermediary host.

This sweet musician sufficiently inoculating himself with the parasite filaria from an elephantoid patient becomes torpid and inactive, and in this state throws himself on the surface of water and soon finds a watery grave. There, in the process of decomposing liberates the ovum of filaria. Whether this ovum find its way into the stomach of the primitive man, who heedless of the rules of sanitation, drinks to his heart's content anything liquid under the guise of water, or the mosquito himself before his demise directly inoculates the unfortunate to convert them into mangeries of filaria as eventually manifested

in the unfortunate cases of the most exposed persons in the semi-child body, is still a point of dispute. The latter theory can be clinically substantiated by the fact that in one of the large institutions in Madras, where the greatest attention is paid to the drinking water, there are a few who have in their blood filaria presumably introduced directly by the mosquito.

The greatest number of elephantiasis in Madras are to be seen at Royapettah, far away from the canal where the people do not depend on any exposed water for drinking purposes, such as wells or tanks. At the same time those who have had the misfortune to live there, will bear testimony to the fact of its being a horrible den of mosquitoes. The immunity which the Chinese possess against typhoid is attributed to their drinking tea (boiled water) and why not by the same argument prove that the great elephantiasis not from drinking water but by direct inoculation of the mosquitoes.

Even granting water to be the vehicle of inoculation when it is utilized for drinking purposes, why go the Mylaporeans and their medical advisers to the Buckingham canal to discover the source of their misfortune, when they themselves confess their drinking water to be the sole cause of their misfortune.

[Their orthodox females object to pipe water being used for drinking purposes and always use well water.]

A theory of percolation into the wells from the canal would therefore be the only plausible excuse to accuse the canal. Reader, lean over the parapets of one of the wells at Mylapore and listen to the horrible hum inside.

The ancients thought it proceeded from Poolhams or devils. No, it proceeds from thousands of mosquitoes, perhaps hundreds of which are finding watery graves to liberate the ovum of filaria in their process of decomposition. Why then this attempt to remove the mole from the innocent canal when beams are floating in their own wells.

Even on the face of the above arrangement if the unconvinced reader leaves a margin for conjecture, we can still prove that the canal is innocent. The numberless animalcules and tiny fishes that infest this saltish canal would never permit a mosquito or its ovum to escape their ravenous appetite.

Let us go still further and see whether there is any percolation from the canal to the town. The town of Mylapore in spite of its deficient drainage, low situation, proximity to sewage form, has been enjoying an astonishing immunity against malaria the offspring of subsoil superfluity. Whence the cause? Every honest citizen of Mylapore will boldly declare that since the introduction of the canal the wells indicate a shallow depth, and the two vast tanks of Mylapore are empty spaces unlike their sister at Triplican which is an unquestionable nuisance. Thus the Buckingham canal forms a great source of subsoil drainage, a want keenly felt in other parts of Madras.

In conclusion let us turn to the fact of alleged increase of elephantiasis at Mylapore. After very careful investigation it has been discovered that a local practitioner with university qualification offered to the credulous people a native nostrum with the help of a Brahmin widow well skilled in the herbal art. This novel offer precipitated several hitherto hidden cases and increased suspicion in those who possessed any malady that simulated the disease, speaking less of up-country unfortunates who poured in to be cured. Naturally Mylapore became a depot of elephantiasis. As reasonably expected no cure was effected. Could this suggestion to destroy the canal be owing to the necessity of possessing a pool, as Bethesda, as an adjunct in the treatment of the disease, as it is repeatedly seen that no tank can contain any water as long as the canal exists.

* The present drainage system at Mylapore adopted only this year is excellent.

ORIGINAL OBSERVATIONS ON INOCULATION AND DIGESTION.

By Major-General E. W. MORRIS,
O.C. Madras.

THE annual meeting in Edinburgh in July 1898, of the British Medical Association, was memorable for the importance of the papers read there upon malarial fever and other tropical disorders, the propagation of which was dependent on germs, which are developed partly in man, partly in other animals. It had long been known that man suffered from parasites visible to the eye, derived from animals, such as hydatids, trina, trichinosis, by eating diseased meat, but the outbreak of plague in Hong-Kong alarmed the world by proving that this epidemic was spread by rats, some of which animals in course of time brought the disease in ships to Bombay, whence it has spread over India.

Professor HAYKINE, who has been in India since 1893, to study the natural history of cholera, and who has done so much for its prophylaxis by his process of inoculation to cause immunity, (just as Pasteur caused immunity by inoculation of animals against anthrax,) made observations in December 1896 at Bombay on plague, which he thus describes in the *British Medical Journal* for 24th September 1898, page 856.—“The first demonstration of the working of the system of inoculation for plague was made in the laboratory on the following plan.—“20 rats from a ship that has newly arrived in Bombay harbour, say from Europe, where there is no plague, are taken; 10 of them are inoculated with the prophylactic against plague, and the other 10 are left as they are. All the 20 rats are then put together, and a rat that has the plague is introduced among them, or they are infected artificially with virulent plague microbes. In the course of time, 8, 9 or the whole 10 of the unprotected rats die of the disease, while none of the inoculated rats die, and none, or perhaps only a single rat will contract the disease among the 10 that had been inoculated with the protective lymph. These observations afforded the first grounds for trying the protective method on human beings.”

This inoculation against plague has been very successful, but the preparation of the lymph is tedious, and the immunity conferred lasts only three or four months, while it is not without risk, as the fever and prostration caused by the operation sometimes have an alarming effect on the patient and his friends, especially as we are told that if his health deteriorates, he is liable to get the plague in spite of the inoculation. This is a very serious prospect, especially as no cure for plague is yet known, and more than half of those who are attacked die, in spite of all treatment. Professor VIRCHOW's “HUXLEY Lecture,” published in the *British Medical Journal* of 8th October 1898, page 1021, records the marvellous progress made in his life time by various observers who compared physiology, (biology in health,) with pathology, (biology in disease), so that he kept an open mind on all medical questions, forming no judgment except upon facts, carefully made and confirmed or refuted.

One of the papers at the Edinburgh meeting was by “Dr. TRENKLE and KOLLE on a most perfect serum method of inoculation for the cure and prevention of Rinderpest,” on which it was noted as follows:—“Many

experiments have been added to this method. On purely theoretical grounds it was urged that it was, physically impossible to infect animals with rinderpest in such a way, as the serum would destroy the virus contained in the blood inoculated at the same time.” . . . But the review ends by saying.—“There can be no reasonable doubt of the efficacy of the method, which might be counted as another triumph of preventive medicine. (*British Medical Journal*, 24th September 1898, page 922, Column I.)”

In the same journal, page 914, Dr. A. G. VORPHEIM, of Java, records observations on diseases epidemic there in persons and fowls, seemingly caused by eating white rice, which were cured by eating red rice, so that apparent trifles may be of physiological importance.

Lastly, in an important paper by Drs. MASON and ROSS (read at that meeting, and printed in that journal pages 849-853), on the connection between the mosquito and malarial fever, it is distinctly said that certain microscopic bodies “RESIST DECOMPOSITION AND DIGESTION” page 853, column 2, line 32. These are drawn on page 851, figure 20. If this can occur in one disease why not in another? Surely further investigation is required.

As matter of fact it is believed that it does occur in other diseases, and has been reported to Government already by Veterinary Surgeon EDWARDS, in his report for 1896-97 on the working of the Civil Veterinary Department in Madras, where he states that in an epidemic of Rinderpest a certain treatment cured 23 out of 25 seizures, after the usual remedies had been tried and had failed.

The treatment was as follows:—

The flesh of cattle was taken from beasts which had died of rinderpest not more than 24 hours previously, (the fresher the better,) cutting it from the hind legs where it seemed quite good, and a broth was made of the raw meat in the proportion of a pound of meat to a quart of water at a temperature of 65°F.

This was macerated for a quarter of an hour, gently pressing the meat now and then with a wooden pestle. The liquid was then strained from the meat, and one quart of it was given to each animal full-grown, viz. one pint in the morning, and one pint in the evening. The calves had only half a pint each morning and evening. The broth was poured down their throats without difficulty, and the sick animals improved at once, so the broth was given to other cattle, not yet affected, and they remained free from the disease. No constitutional disturbance whatever appeared in any of the cattle, well or sick, and the latter made a good recovery.

This was daily reported to Government, and when plague broke out it was suggested that analogous experiments might be tried, but the papers above quoted had not then been published, so the authorities did not believe in ingestion, feeling certain that the gastric juice would dissolve and destroy all germs, and placed their faith in inoculation, stating there was no time to investigate ingestion, or make any experiments with it.

But in September 1898 experience with ingestion advanced another step, for foot-and-mouth disease broke out at Salatha, Nilgiris, in my herd of 60 cattle, and the

serum treatment was used in which the cow's milk remained having failed.

It is more fatal to English than to Indian cattle, and to all extent, this cow and those which died straight off, like an English bull in an early stage of the disease (1st or 2nd day), was so ill that he could eat nothing, the mucus of his mouth being white now. In this condition it was considered dangerous to give him the raw-meat bath made from the flesh of the cattle which had died from the disease, for fear he might get blood-poisoning by having this flesh applied to the raw surface of his sore mouth, so the following plan was adopted as an experiment.

A caprine cow, three days after recovery from the attack, was milked twice a day, giving three pints of milk in the morning, and four pints in the evening, so this cow's milk was given to him in a warm, soft, bran mash, one pint in the morning, one pint in the evening, when the disease at once diminished in severity, inflammation subsiding, and fever abating so rapidly, that the attack ran its course in half the usual time, (i.e. in 4 days instead of 8 days), and on the fifth day he grazed spontaneously on the hill side. It did no harm, but seemed to have really a curative effect, without any constitutional disturbance.

Seeing this, the rest of this cow's milk, (five pints,) was also divided among six calves twice a day, when they also improved at once, and were able to suck as usual. Both the bull and the calves had this treatment for only one day. On their convalescence this cow's milk, given in bran mash, was eaten by fifteen other cattle affected (7 cows, 8 calves), all of whom quickly recovered, it being given to them as soon as they were found to be attacked —

The rest of the herd were separated from the sick ones, and the milk of this cow was given to them as a prophylactic, as far as it would go, and the disease did not spread among them.

It is to be hoped that other people will repeat these experiments, for if generally unsuccessful, what a blessing they will bring to the human race.

If this isotic ingestion succeeds in curing foot-and-mouth disease, why not small-pox, another epidemic which attacks cattle?

Even in 1898 there are strong objections felt to vaccination by many people, at home as well as in India, but nowhere in the world is any objection felt to drinking milk of the cow, which in India is the object of great veneration by all castes alike.

When the new Vaccination Act was passed in 1898, the clauses of the old act which made vaccination compulsory, were not renewed, for though Lord SALISBURY'S Government had a majority of about 150 votes in the House of Commons, the force of public opinion was so strong that it was felt impossible to compel people to be vaccinated against their will. The inconvenience of the operation is generally slight, but all of us have seen occasional cases where the inflammation locally was very severe, and the general constitutional disturbance alarming, so if people can be protected against small-pox by drinking the milk of a cow which has obtained immunity against the disease, every parent will welcome ingestion to protect children against disfigurement, blindness and death.

The chief reason at times for the opposition to vaccination is the universal belief that with the vaccine and other diseases are introduced into the system, and that this does occur now and then, but it is the patient's own fault, because it persistently refuses to accept the Contagious Diseases Acts against syphilis, though it has no objection to enforce them against ringworm, and various other infectious disorders.

Only the progress of education and knowledge can remove these prejudices, and when the public came to the profession with not having discovered the germ of syphilis, medical men can only heap abuse and pursue their studies patiently, but they have every right to demand that in this they shall not be impeded by senseless dogmas like that of the anti-vivisectionists, so-called.

People are perpetually quoting the words of Shakespeare, (Hamlet, Act 1, scene 5.) "There are more things in heaven and earth, Horatio, than are dreamed of in our philosophy," yet whenever any new discovery is made it is sure to be met with a storm of indignation and contempt.

So we record here some facts noticed by ourselves and our friends, keen observers, to try to induce other people to repeat the observations, for confirmation or for refutation, so that the world may know in course of time what is fact, and what is fiction.

In the *Madras Mail* of 27th October 1898, a correspondent from Bangalore mentions that the plague has attacked the squirrels as well as the rats, and that a cat which had evidently dined off an affected rat was found this morning on its last legs — Another writer reports another cat being found sickening for plague, with its glands enlarged, &c. Now unless compelled by starvation, a cat will not touch a dead rat which has died a natural death, though she may accept a killed rat, if quite fresh, but if it is a male rat she will not look at it. This refers only to the domestic cat, a household pet, which likes the sport of the chase to whet her appetite, but does not like her game to be "high." No one can answer for the vagaries of the wandering "Tom" cat. It is well known that when a stag is killed, it has to be "gralloched" at once, for if the generative organs are not removed the taste of the venison becomes so strong, that the meat is quite uneatable. As these cats at Bangalore took the plague, it shows that they probably caught the infected rats alive, and killed and ate them. Kites as a rule pick up dead rats, while hawks prefer to catch them alive and kill them. With all carrion-feeders it seems that nature has made some provision for the preservation of the lives of her creatures, and what is more, she arranges that they can thrive on what is inimical to other forms of life — hence the proverb, "what is one man's meat is another man's poison."

Some years ago a Forest Officer, a keen observer of Natural History in all its aspects, noted a strange mortality among some Irias, a primitive tribe living on the Nilgiri Hills. Rinderpest had destroyed many cattle at the foot of the hills, where it had infected even the Bison and the Sambur. Some of the latter were found dead or dying near a stream, so the Irias slaughtered the dying and cut the bodies of dead and dying animals apart, eating them greedily in the jungle, when several men soon became very ill, the disease being no doubt that

slightest and smallest were being consumed with terrible malignant consequences.

Reading up the ages, I find the information that the men who suffered so severely had eaten the flesh of the dying animals which they had killed, while no ill effect resulted to those who had eaten the meat of the animals which were found already dead. Indeed, among the Lulus, Kotors and other hill tribes, the members are carrion-feeders of the foulest kind, no rotten meat comes amiss to them, yet they are generally sleek, smooth-skinned, apparently healthy, with sound white teeth.

Readers of Sir Walter Scott's novels will remember that "braxy mutton" is mentioned as the perquisite of the Scotch shepherds, yet nothing is said about any ill effects to those who ate the flesh of the sheep which died a natural death. Similarly the Kotor remains free from disease while he eats only the flesh of animals which have died a natural death, i.e., from illness, not from the butcher, which is a fact, explain it who can.

It is the butcher who disseminates sickness and death, for when he slaughters a beast he is quite aware if the animal is suffering from rinderpest or other disease, so when this is the case he sells the meat at a cheap price to the poor natives, who are as ignorant as they are poverty-stricken, and who often die from eating it, especially if the meat is at all under-done. The mutton in the hills is generally better than in the plains, but even the sheep is not above suspicion, and if (as often happens) the liver is the only part diseased, the butcher sells the meat to his well-to-do customers, while the liver finds its way to some poor family, and when people die they do not suspect the food, but the death is put down to dysentery or cholera, which all regard as mysterious.

The Hare, though supposed by modern Europeans to be a wild animal, and a clean feeder, in India is often the victim of hydatids, especially near native villages, so its flesh should be avoided.

In Deuteronomy xiv, there are lists of animals which Moses said were permitted to be eaten, and of others which were forbidden to the Hebrews. These lists seem very curious to Anglo-Indian officials who know the habits of the natives and of animals in hot climates, so that the ancient ideas of sanitation seem to be confused.

Verse 21 says "He shall not eat of anything that dieth of itself, thou shalt give it unto the stranger that is within thy gates that he may eat it; or thou mayest sell it unto an alien; for thou art a holy people."

That is exactly like the feeling of a Brahmin in India to the present day, who may not eat certain things, but they may be given to the pariahs who do the dirty work of the village, or the butcher may sell the meat to an unwary outsider.

Verses 4 to 20 give lists of clean and unclean animals. According to Moses an animal is clean which (v. 6) parteth the hoof and cheweth the cud," viz., (v. 4) "the ox, the sheep, the goat; the swine is unclean, (v. 8), because it divideth the hoof, yet cheweth not the cud." Similarly, (v. 7) the camel, the hare and the coney are unclean, for they chew the cud, but divide not the hoof."

Verse 11 says "of all clean birds ye shall eat," yet neither does nor in Leviticus xi is any list given of clean birds,

but in both chapters certain birds are forbidden as unclean.

Thus it is evident that Moses forbade the Hebrews to eat only animals which were vegetable-feeders, but since he was not a close observer of domestic animals in Egypt in his time were better fed than they are in India at the present day, for all Europeans who can afford to eat meat only from sheep belonging to western cities, and poultry well-fed at their own bungalows; for all domestic animals belonging to natives are scavengers, and may be said to devour all sort of sewage and garbage in and near villages and towns.

As no list of "clean fowls" is given, one cannot say if Moses considered partridges clean or not, but they will in India eat carrion, for the writer has seen a covey of partridges feeding on a dead camel, the stomach of which was overpowering.

In Leviticus, xi, 21-23, Moses allows things to be eaten which no European would touch—"These ye may eat, of every flying creeping thing that goeth upon all four which have legs above their feet, to leap withal upon the earth; even these of them may ye eat, the locust after his kind, and the bald locust after his kind, and the beetle after his kind, and the grasshopper after his kind. But all other flying creeping things, which have four feet, shall be an abomination unto you."

Moses does not seem to have observed that insects have six legs, not four legs, so what "other flying creeping things," he means cannot be guessed, but it is certain that in India at the present day the natives make no attempt worth mentioning to keep their dwellings or roads clean, but leave the scavenging to be done by oxen, sheep, goats, pigs, dogs, jackals, and all sorts of birds and insects, especially white ants, wasps, beetles, flies and mosquitos, of which the last two undoubtedly spread disease after touching sewage.

Some impecunious Germans maintain that it is quite safe to eat meat infested with hydatids or trichinella, if it is cooked at a certain temperature, but British subjects would prefer to avoid such diet, and insist upon eating only meat of animals which had been passed by a sanitary inspector of slaughter-houses and butchers' shops.

Even milk and butter must be inspected, with the farms and dairies where they are made, for these important products of the cow are of such unstable composition in a chemical sense, that they are very easily spoiled, while typhoid fever and other infectious diseases have been proved to be spread by milk, merely because the milk-cans were washed with water from a contaminated source.

Yet this milk and this water had no appearance, taste or odour to excite suspicion, so minute was the proportion of diseased products in them, but patients have died of this infection.

Therefore, if after death the raw-meat broth made from animals which have died of rinderpest is found to cure rinderpest, the post-mortem change is very remarkable, and is worthy of being studied.

Already people with weak digestion have been treated with raw-beef-julor for certain complaints, and have recovered, after all other treatment failed, so the sequestration treatment is only another step.

It is not wise to try to give plague patients such meals as their flesh of human plague-patients, but why should we not try to cure plague by the broth of the flesh of plague-stricken rabbits, as plague is a bacterial disease, as well as rinderpest?

Rats are plentiful enough, and rabbits infected from plague-stricken rats would afford a broth not unpleasant to taste, and it remains to be seen whether the serum of those that recover has the same prophylactic property. Further experiment will of course lead to better results, and less crude ways of administering the remedy. So far no laboratory is required, but a godown with a few rats and rabbits; elaboration can follow.

The lacto theory will of course require more testing, but it might be tried on cows, or goats, or pigs, near the plague-camps themselves, under intelligent supervision, which is all that is wanted.

Observations should also be made by experiments on the flies in plague camps, to ascertain if infusions of flies caught on plague-patients, if applied to rats or rabbits would give plague to these animals. It is quite possible that infection may thus be carried, and if it be proved, it would be worth while to try if cattle in Africa can be protected from the much-dreaded Tsetse fly, which is so fatal to them, and which has caused recently so much mortality among the transport animals with our force in Uganda.

A very important address was recently given by Professor KOCH to the German Colonial Society on his return from German East Africa, in which he described the observations he had made in that territory. He found a study of *Texas fever* in cattle of great assistance in giving a key to the origin of tropical malaria. Cattle disease was transferred from one animal to another by the sole agency of that animal parasite the tick. (? *Melophagus bovis*). He had been able to infect sound cattle with ticks taken from diseased ones; moreover he had rendered cattle immune against *Texas fever* by inoculating them with the ova of ticks taken from diseased animals.

Malarial fever was in many respects like *Texas fever*, and he had arrived at the conclusion that in the human subject, mosquitoes played the part which ticks played in cattle disease. Professor KOCH found they were present where malaria prevailed, and where there were no mosquitoes there was no malaria, as in a certain small island on the coast of German East Africa. He called attention to the circumstances that the natives there were proof against infection, and where natural immunity existed, there was hope of affording artificial protection. By microscopic examination of the blood the exact stage of malarial fever could be ascertained, a thing of great importance, for much depended upon the administration of quinine before the attack, or in its early stage. Doctors specially trained in bacterial observations and microscopy should be sent to Africa, West as well as East; and if science can only cope with malarial fever successfully, the conquest will facilitate the prosperous development of some of the most

fertile regions in the world. What the same eyes of Africa may be taken as equally good of India, where the deaths from malarial fever exceed those from all other causes put together, so it is to be hoped Government will excuse its best trained medical officers from routine duty and will depute them like Dr. Koch to special investigations, which are likely to prove far more valuable to the empire.

In connection with the action of ticks and mosquitoes it is worth noting that Badagas, Kurumbars, and other wild-tribes in the Nilgiris, are very fond of honey, and when they find honey-combs they eat not only the honey, but also the immature bees in the cells, pupae or larvae, which they say taste like cream. They take the combs, regardless of the bees swarming round them, and though frequently stung, they feel no pain, as the stings are followed by no inflammation or swelling, as happens in ordinary people who do not eat bees.

The mongoose is supposed to have immunity from snake-bite, and it is not known for certain whether it escapes because the venom of the snake is lost in its fur when the snake tries to bite it, or whether the immunity is caused by the mongoose's habit of eating snakes.

But other animals without fur attack and eat snakes with immunity, i.e. pigs, kites, pea-fowl, the adjutant bird, and various other wild animals in the jungles, who share the snakes with their young ones, so the latter may be supposed to be immune against snake-poison very early in life. Moreover musk rats attack scorpions fearlessly, whatever their size, and devour them, while large black ants eat the remnants greedily, and will join in packs to hunt small scorpions, which they rapidly cut to pieces with their jaws.

Snakes eat snakes, and spiders eat spiders, as most people can observe for themselves while DARWIN mentions, that the earth-worms have cannibal habits. In the south of India the belief prevails that a diet of earth-worms will cure rheumatism, and the natives in some places stew them for this purpose, putting them first in vinegar to make them vomit the earth which they have swallowed. The writer was induced to taste this stew once, and found it very good, tasting like shrimps. Some people are very fond of soup made of squirrels, or of guinea-pigs, and this is really very good when made like jagged hare. These animals are very clean feeders, and can be kept in hatches in the compound, providing an agreeable change of diet, much safer than hares or rabbits or partridges shot near native villages. The struggle for life is intense enough, as we all know, but were it not for the wise provision of nature detailed above, all living beings would suffer still more in trying to live. May this encourage us to observe nature more closely; and follow her guidance.

SEVERE LONG-STANDING GASTRIC AND INTESTINAL DISORDERS OF REFLEX UTERINE ORIGIN, CURED IN TWO MONTHS BY THE USE OF THE UTERINE STEM.

By JAMES R. WALLACE, M.D., F.R.C.S.I.
*Fellow of the Obstetrical Society of London,
Member, British Medical Association,
Formerly Resident Surgeon, Edin Hospital
for Women and Children,
Calcutta, etc.*

In April last I was called to see an Anglo-Indian lady (Mrs. C—) aged 29, of fairly good physique, a widow, childless, who was suffering from vomiting, which took place regularly half an hour after meals every day, and which symptom was attended with severe pain about the epigastrium and abdomen during each menstrual period, and with diarrhoea and dysenteric symptoms superadded during this epoch. This condition of things had been present for nearly three years, that is during the entire period of her widowhood. She had for some time been under the care of Drs. CHROMBIE and MCCONNELL, and others, but beyond receiving a little palliative relief, the persistent post-igestion-vomiting and the recurrent menstrual aggravation of this symptom and the attendant intestinal disturbance continued unabated. A remarkable feature in this case was the distinct absence of much emaciation, proving that while vomiting followed the ingestion of food by a short interval, there could not have been a complete emission of the gastric contents. The history of the case struck me as being peculiar, and I was strongly impressed with the noticeable aggravation of symptoms during the catamenial period. At the time of my visit I found that the patient was in the middle of two menstrual periods, and I could not discover any enlargement or tenderness of her liver, nor anything abnormal about either the stomach or the intestines to account for her sufferings. Enquiry elicited the fact that since her husband's death, about 3 years previously, her menstrual flux had become diminished in quantity and altered in colour, being more dark and clotted and lasting for three days only, instead of five. It was also observed that nausea and vomiting during this period were most persistent, whilst marked intestinal pain accompanied by frequent diarrhoeic motions mixed with mucus and blood, and attended with much tenesmus, not only ushered in, but continued throughout the period of menstruation. Feeling convinced that the trouble I had to deal with was of a reflex uterine origin, I suggested an examination of the uterus and appendages *per vaginam*. This was allowed and I found as the result, that she had an anteverted uterus and a stenosed cervical canal. I accordingly gave it as my opinion that the gastric and intestinal disturbance, though of such long duration, and of such a distressing character, treated as they had been by the most skilful physicians, and uncombated as they were successfully by a large and varied stock of medicinal remedies and drastic preparations of a well-studied order, were unquestionably reflex in character and utero-ovarian in origin.

On the 1st of April I introduced a 2½ inch silver uterine stem. On the 18th of April the patient menstruated, the discharge was very free, there was little or no intestinal pain, there was some relaxation of the bowels but no tenesmus or other dysenteric disturbances. The patient vomited twice on the 1st day and once on the 2nd day of the flow, and after that there was no more nausea or vomiting for a week. The stem was retained *in situ* for 8 weeks, and during this period, vomiting took place about nine times, with an interval of 5 or 6 days or more, but there was no return of intestinal disturbance. Instead of diarrhoea, however, there was a tendency to constipation, and this was met by the daily injection of two pints of warm water, with which 20 grs. of boric acid was mixed. It is important to state that from the date that the stem was introduced, the patient, as advised, partook of an ordinary diet of meats, vegetables, fruits, puddings and salads. The only medicines administered during the period of treatment was an occasional dose of castor-oil emulsion with terebene. The patient was married two months ago, and is keeping perfect health.

SOME FURTHER NOTES ON THE USE OF BROMIDE OF STRONTIUM IN EPILEPSY.*

By ANTONY ROOPE, M.B.C.P. Irel.,
*Professor of Medical Jurisprudence and Public Health in
the Catholic University Medical School, Dublin;
Examiner to the Royal University
of Ireland.*

In 1894, and again in 1896, I published some notes, with cases, on the use of the bromide of strontium in epilepsy. I have many of the cases then mentioned still under my observation, with a considerable number of others. Perhaps therefore some remarks founded on a more extended experience in the use of this bromide may be of interest to the profession. Unfortunately I cannot give the results in all my cases, as some of my patients communicated with me only by letter, and I am therefore unable to follow the course in all. In the majority of cases, however, I have been able to learn the results of the treatment.

I have not met any case in which the bromide of strontium given in the doses and method I will mention has failed to diminish the number of the attacks. In many instances there has been no return for periods extending to two, three, and even four years. Some of these cases may be considered "cured"—that is, that there will be no return of the attacks when the medicine is permanently left off. I cannot say definitely that this is so, for the reason that I always recommend the patients to continue the medicine, even though there has been no return for a long period. I do this all the more as I have not found the continued use of bromide of strontium to be followed by any bad consequences, and many of the patients have been taking 1 drachm daily without intermission for more than three years without any complaint. In this respect the strontium salt has an immense advantage over the potassium salt, which has frequently produced serious physical

*Reproduced from *The Lancet* by request.

and mental changes when continued for a long period. Moreover, patients taking bromide of strontium frequently suffer from intense depression. Several of my patients were obliged to leave it off owing to this; in fact, several expressed their feelings by writing me that they would rather suffer from the fits than from the depression produced by the medicine. I have not noticed this at all in those taking the bromide of strontium. The potassium, too, is poisonous in large doses; the strontium is not. On this point I may quote one of the most recent authorities, Dr. DIXON MANN, who in the second edition of his excellent "Manual of Medical Jurisprudence" says that "strontium salts cannot be regarded as poisonous." I have myself given 3 drachms daily for weeks without any unpleasant symptoms. I consider, therefore, that the strontium salt excels that of potassium in being more efficient and in not being followed by dangerous consequences when it is continued over a lengthened period: and as it is not poisonous it can be given in as large a dose as may be required to control the attacks.

In my earlier cases, being influenced by the remark of BROWN-SQUAND, that the combined bromides were more useful, I gave the bromide of strontium combined with one or more of the other bromides, but for a long time I have given that of strontium alone. I usually commence the treatment by ordering half a drachm night and morning in some vegetable tonic infusion. Should that dose not control the attacks, I rapidly increase it till I have found the quantity which will suit the individual case. I direct the patient to take 30 grains at once in those cases where there is any warning of the attack and to repeat this every hour if required. By this means I have no doubt the attack has been frequently prevented. I may repeat that in my experience in order to get the full benefit of the medicine I have found it necessary to give it in large doses and to continue it for a long period. Since my first communication several members of the profession have written to me saying that in their cases they have not found the same good results. I invariably find that in these cases the dose given has been too small and consequently that my practice has not been followed. I need not say that each case requires to be studied on its own merits and any exciting or predisposing cause lessened or removed. I do not think it necessary to go any further into this question, as these notes are not upon the general medical or surgical treatment of epilepsy, but upon a special medicine, nor need I give my experience in the use of any other of the many remedies proposed. Many of these I have tried, but none have given me the same good results as I have found by the use of bromide of strontium.

I should say, however, as I have more fully explained on a former occasion, that I regard the question of diet as one of much importance. I direct my patients to restrict themselves to fish and vegetables, and I generally find no great difficulty in having my orders carried out. When the attacks diminish in number, if I am pressed to do so, I allow the more easily digested meats twice or three times in the week.

I propose to return to this subject in a subsequent communication and to give details of some of my cases.

EAR-ACHE AS A FERRUGINOUS SYMPTOM OF LOCK-JAW.

By Dr. LUKMAN-UD-DOWLAH,

Staff Surgeon, H. H. The Nizam's Medical Service.

IN persons suffering from Tetanus, ear-ache has often been found to be the first symptom of the disease.

The following three instances establish the truth of this:—

(I.) A boy 19 years old, suffered from malarious fever for two months, and was for six days confined to bed from excess of Epistaxis. I was called in, and found him exhausted from loss of blood.

From physical examination, the heart and lungs appeared to be in a healthy condition. The liver and the spleen, however, were enlarged. There was swelling of the feet. The patient felt difficulty in speaking, and complained of nothing but general weakness owing to loss of blood. Internal and external remedies were applied, and measures for stopping the hæmorrhage were adopted.

This diminished the flow of blood, but did not entirely stop it, as it came on at intervals. After three days he complained of pain in both the ears, rather more in the right, which made him restless throughout the night. On examining the ear it shewed no sign, nor was there any pimple or inflammation or discharge of matter. On enquiry I learnt that the patient had never before suffered from ear-ache. I prescribed the ordinary ear-drops, containing glycerine, morphia and cocaine. The next day I was informed that the patient could not open his mouth owing to great pain. When I visited him the second time there was no symptom of swelling in or about the ear; and the boy being asked to open his mouth, did so with difficulty to the extent of about two fingers' breadth. This, along with other characteristic symptoms, convinced me that this was clearly a case of Lock-jaw. Hence instead of treating the ear, I commenced the treatment for Tetanus.

The patient was kept so much under the influence of Chloral hydrate combined with Bromide of Potash that he was fully under its effect, except when medicine or food was to be given to him.

Although the day after I began the treatment, the jaws appeared to be rigid, yet, on the 3rd day, a change for the better was noticed, and by continuing the above medicines, in ten days the patient was able to open his mouth easily, while the ear-ache had entirely disappeared.

(II.) Was a girl 17 years old, who, under the supervision of a native midwife, was delivered of her first child, and on the tenth day was brought to me to be treated for fever. The third day after coming to me she complained of ear-ache which had made her restless during the night. Formerly her ear used to discharge matter. Thinking it was the same complaint, she asked for ear-drops. I used the ear-drops, and applied the extract of Belladonna and Opium with Glycerine to the part surrounding the ear. On the fourth day of her admission, that is, the second day after feeling pain in her ear, and the fourteenth day from her delivery, her jaws began to get rigid, and eighteen hours after this, all the symptoms of Tetanus became apparent. Her friends then removed her to be treated by *vaidee*, and I heard that she died 48 hours after the symptoms of Lock-jaw had fully developed.

(III.)—A boy 15 years old, who had been accustomed to go about barefooted, had his right foot wounded by a piece of glass, and beyond tying it up with a piece of dirty cloth, he did not attend to it, and still walked about barefooted. He came to me limping, and while asking me for treatment for the wound, complained to me of feeling pain in the ear. On inspection I found the wound to be in the middle of the plantar region, an inch long, and oblique in direction. The appearance was of a superficial punctured wound. It was discharging blood and pus, due to the patient's carelessness. The wound was dressed regularly. On the fourth day after this, the boy was brought to me in a dhooly, with all the symptoms of Lock-jaw. The treatment employed was the same as in the case No. 1, but it proved ineffectual.

THE CONCLUSION.

From the facts in the foregoing cases, the following conclusions are drawn :—

Case No. 1 shows that after an excess of Epistaxis, the ear-ache led to the symptoms of Lock-jaw.

In case No. 2 and 3, though the patient's ear-ache was an old complaint, yet it proved to be the first symptoms of Lock-jaw. The opportunity for the preliminary treatment afforded in case No. 1 was not given in these two cases, as full symptoms of Tetanus developed before treatment was sought. It would therefore not be wrong for the physician to regard ear-ache as one of the preliminary symptoms of Lock-jaw.

DIAGNOSIS.

The ordinary ear-ache mostly affects one ear only. On the other hand if ear-ache is a preliminary symptom of Lock-jaw, it affects, more or less, both the ears. In the case of ordinary ear-ache, inspection generally shews the organ to be abnormal, viz., there appears either a pimple, discharge of matter or inflammation, which would not appear when ear-ache happens to be a first symptom of Lock-jaw.

In the latter case, along with ear-ache there is commonly felt a rigidity of the jaws, which would not be perceptible unless the physician carefully examines his patient. If, however, a patient's ear is affected by some local ear disease and, at the same time, the ear-ache appears as a symptom of Lock-jaw, the case becomes complicated. The physician, in order to make a correct diagnosis, will have to be careful in noting the peculiarities in the patient's condition, such as hemorrhages, epistaxis, &c. of a female patient in the lying-in state, wounds or other injuries, with other local circumstances, or effects of cold or damp, also whether the patient is predisposed to the disease. How ear-ache appears as a symptom of Lock-jaw may be thus explained :—As in the case of Tetanus, the spinal chord and the nerves are affected, and consequently spasm arises in the muscles. Moreover, it has often been observed that trismus precedes tetanus, but in some cases preliminary spasm is met within the muscles of some part or other of the body. Thus either a finger gets stiff, or some particular muscles shew contraction. Consequently, the minute nerves distributed to the muscles interior of the ear viz., the tensor Tympani and Stapedius become affected, and hence arises the pain. It is also possible that in the case of trismus when the muscular fibres are affected, the internal nerves of the ear are likewise sympathetically affected.

Indian Medical Record.

1st December 1892.

THE MALARIA PROBLEM IN THE LIGHT OF EPIDEMIOLOGY.

A PAPER of particular interest at the present moment, from the pen of Dr. ANDREW DAVIDSON, appears under the above title in the pages of the *Edinburgh Medical Journal*. It was read by the author before the British Medical Association, 27th July 1892.

This paper is an earnest attempt, "to enquire how far the mosquito hypothesis in any of its forms, or in some possible modification, can be made to harmonise with certain well-established epidemiological facts which will find their explanation when the true solution of the problem has been attained."

The author in the first place points out that there are three theories at present engaging attention, all of which implicate the mosquito in the spread of malarial fever.

First we have MANSON'S hypothesis that the plasmodium is a normal parasite of the mosquito or of some other suctorial insect, "passing from mosquito to larva, and from larva to mosquito, in never ending series." The parasite is supposed to gain access to man indirectly, thus the infected mosquitoes die and contaminate soil or water with the parasite, which enters the human system by the medium of water or dust.

BIGNAMI'S theory is that the malaria germ, present in malarious localities as a soil parasite, is inoculated into man by the mosquito and allied species of insects.

KOCH believes that man is infected by inoculation, as the Texas fever in cattle is transferred from one herd to another solely by the agency of the tick, so he supposes, is malaria propagated. The mosquito, he says, "receives the parasites, transmits them to its eggs and the young larvae, and only the next generation is able again to infect with malaria parasites."

The epidemiological facts which Dr. DAVIDSON discusses in connection with these three theories are the following—(1) Epidemics of malaria resulting from soil disturbance; (2) the invasion of countries and districts previously free from the infection; (3) the extinction of malaria in countries where it formerly prevailed; (4) slow-spreading epidemics of malaria, in which, as the disease advances, it dies out in the region just visited; (5) local epidemics caused by the formation of artificial marshy foci; (6) Ship malaria; (7) the prevalence of malaria in northern latitudes at the season of the year when the temperature is under the freezing point, and when insect life is in abeyance.

The literature pertaining to the phenomena noted under 1, 2, 4, 6, 7, is of such an unsatisfactory nature, and so lacking in precision, the phenomena are so imperfectly understood; while their claim to be regarded as facts, has been shown in so many instances to be founded upon faulty or fallacious observations, that, we do not think much advantage can be gained by the attempt to bring them into harmony with theories that are equally nebulous.

theories (a) and (b) are those of different types, they are clearly not comparable, there are things to be reconciled to the mosquito theories?

Talking of the disappearance of malaria from many parts of England and Scotland, Dr. DAVIDSON asks, "What are the signs of malarial land and its disappearance of some species of gnat or other malarial insect from these localities? There are still, fortunately for science, some malarious districts in England, and it would be of extreme interest to ascertain whether any species of gnat are present in these which are absent from non-malarious localities. It is said that there are nine species of gnat in Great Britain. Are any of these peculiar to malarious districts?"

The suggestion here thrown out is all the light Dr. Davidson has to throw upon this question. So that what appears to be one of the simplest problems in malarial epidemiology is still unsolved. What is even more curious is that the key to the riddle is actually in England, but no one appears to be looking for it. In the meantime we read of Royal Commissions rushing off to search for it in tropical Africa, where all the conditions are certain to be much more complicated.

Dr. DAVIDSON does not allude to the fact that there are plenty of mosquitoes to be found in parts of England, but this is certainly the case about Plumstead and Southampton.

Under (5) he says, "we have also examples of quite local and temporary outbreaks, clearly dependent on the establishment of marshy foci in some locality where malaria is little in evidence or altogether absent."

He fits these into the mosquito theory as follows.—"If the plasmodium is a normal parasite of insects which live in marshy localities, the creation of a marsh may be supposed to lead to the immigration into such locality of an insect previously absent from it. Up to a certain point, therefore, these local epidemics are explicable on this hypothesis, but the sudden appearance of one or more plasmodium-nourishing insects in localities from which they were previously absent, and the rapid infection of an entire community, present difficulties not to be ignored."

From this it would appear that what Dr. DAVIDSON has to tell us concerning two of the simplest and best known facts concerning malaria, is most unsatisfactory, and adds absolutely nothing to our knowledge of the subject.

Dr. DAVIDSON is well-known as an ardent believer in what he calls epidemic as distinguished from endemic malaria. It is his constant regret that there are so few examples to quote from; in the absence of any more modern data he is very fond of the great Mauritius epidemic of 1866-68, and of a less known epidemic which occurred in Sweden in 1846.

Regarding these epidemics and other sudden outbreaks of malaria which he attributes to soil-disturbance, he mentions one point of great importance in connection with the mosquito hypothesis, it is, that in all these epidemics every form of the disease is present, and that the appearance of the different types is regulated by the seasons.

Under the head of soil-disturbance he says, "A well known instance of the same kind is that recorded by WENZEL, of the severe epidemic that broke out during the

consequence of the digging up of the remains of the North Sea. I mention it, because there seems to be in connection with it, as in many other epidemics of the same kind, a point which cannot at present be fully explained in Manson's hypothesis. It is this: There is not only a corresponding increase in the average severity of the form of sickness in the summer months, but also a preponderance of the shorter rhythm, and an approximation of the continued type; while with decreasing intensity in the colder months there is a corresponding lengthening of the rhythm to tertian and quartan. Upon the assumption that the infection is caused by the setting free of long imprisoned malarial germs from the soil, it is difficult to explain why the parasites of the short-rhythm fevers should monopolise the hot season, and those of the tertian and quartan the cold season respectively. They are "shaken-out" of the soil, hypothetically, at the same time, yet the different parasites do not give rise to fever as they are brought to the surface, but each type appears in its regular season just as in endemic and epidemic fever not arising from soil-disturbance."

On the subject of soil-disturbance as a cause of malaria, Dr. DAVIDSON alludes in a foot-note to a paper which appeared in this journal on the 16th December 1897, by Surgeon-Major MOORE. This paper contains a large amount of evidence to show that the malarial fevers which ravaged Hong-Kong in its early days were not due to soil-disturbance, the contrary view has been strictly maintained both by DAVIDSON in his "Geographical Pathology" and by MANSON, in his "Tropical Diseases." It is curious to note that in the paper we are discussing, Dr. DAVIDSON makes no allusion to Hong-Kong as an example of soil-disturbance malaria. He is satisfied with the less known cases of Panama, Brazil, and Mauritius.

Dr. DAVIDSON's paper, to which we fear we have not done justice, is a much wanted and very valuable contribution to present day malarial literature. It is however mainly speculative and appeals to us less on this account.

It is not surprising to find, that having weighed the three theories referred to and found them wanting, that he should be ready to still further complicate the situation by adding a modification of his own.

His views, somewhat abbreviated, are as follows:—

The malaria parasite is not dependent on man for existence. It meets him, to his horror, in regions previously uninhabited. This fact in its history is adequately accounted for on the supposition that the plasmodium lives and multiplies in the soil of malarious localities, and finds its way into the system in water or air, or, as BIGNARDI suggests, by inoculation, the virus being conveyed from the soil in which it is present by the agency of mosquitoes or other insects. But on this theory which implies that man is merely an accidental host of the plasmodium, it is difficult to explain how a soil parasite should adapt itself so perfectly to life in man, should develop and multiply in the system, and become latent there until conditions favour its renewed activity. This perfect adaptation to its human host is not what one would expect in a parasite whose normal life-cycle is in the soil. The theory that the parasite is transferred from man to the mosquito, in which it undergoes development, and in the second generation is able again to infect man by inocu-

little is known of how it enters and maintains itself in the human body. Interference of the mosquito with the circulation or why the disease is absent from countries where mosquitoes abound.

We have difficulty in accounting for the presence of malarial fevers in certain regions, on Manson's hypothesis, that the plasmodium is a normal parasite of the mosquito. This mosquito-bred plasmodium is hypothetically there to infect him as soon as he intrudes into a malarious region. But this theory is not without its difficulties. Man is clearly not an alternative host of the parasite, in the sense that it can run in him the same cycle as it does in the mosquito, and can thus take the place, so to speak, of the mosquito in relation to the parasite. Man is the alternative host only in the sense that the parasite runs one part of its cycle in him, the other and complementary part in the mosquito. May we not rather conclude that man and the mosquito are both necessary for its propagation, its cycle being from man to mosquito and from mosquito to man in never-failing series? There is no evidence that it can complete its life-history in the mosquito alone. Are we not therefore justified on the ground of analogy, in assuming that the malaria parasite also requires two hosts for its continued existence? Should this view, that the malaria parasite runs a double cycle, and that other animals may take the place of man as its host, prove correct, as I think it will, some of the difficulties which at present surround the etiology and epidemiology of malaria would be lessened or disappear.

:O:

QUACKERY AND QUACK ADVERTISING IN INDIA.

II.

We will now cast a glance at some of the marvellous cure-all concoctions which Mr. Kaviraj NOGENDRA NATH SEN GUPTA so lavishly advertises all over India, and for which, after the usual fashion of quacks, all sorts of miraculous and impossible virtues are claimed.

In the first place there is the Keshranjan oil, the same that was sent to the Lieutenant Governor of Bengal, whose Private Secretary's letter in acknowledgement has been turned into an advertisement to gain notoriety.

It is claimed for this oil that "It cures baldness, removes dizziness, debility of the brain, melancholia, short sight, weakness of body, and of memory, vertigo and other similar maladies." Incidentally we learn that "if the hair is diseased, it cannot suck the neuro-vital fluid that keeps it in proper order."

A marvellous oil indeed! but why the advertiser should imagine that Sir JOHN WOODBURN was in need of it we are at a loss to know. *Difficile est satiram non scribere*, so we will only say that it is not a delicate compliment to assume that the ruler of Bengal suffers from any of the derangements for which it is said to be a specific.

Wonderful as the Keshranjan oil is said to be, it appears to sink into insignificance when compared with the Himsagar Pills, for we are told in the best oil among all the Himsagar medicines, and truly it would be if we could believe only a smattering of what is said about it. We are told that "it removes dizziness of the head, headache, heat in the head, troubled condition of the mind, forget-

fulness, weakness, palpitation of the heart, nervous debility, night dreams, and all other diseases arising from disordered mind."

The name of "Shastri Bhattacharya" is given to what claims to be a specific for leprosy. In the usual strange and unscrupulous style, Mr. K. N. N. Sen Gupta, does not hesitate to say, "We have tried it to remarkable success with great success and can safely recommend it." It "will remove all complaints in connection with leprosy from the earliest stage of impurity of blood to the last stage of putrefaction of muscles and flesh."

What hope is there for the unfortunates upon whom such human vultures prey?

Another good sample of unscrupulousness is found under the head of "Panchatikta Bittika, or Anti-malarious pills" which are advertised as "the specific for every variety of malarial disorder." The author does his best to turn the people against the use of quinine, and to nullify the attempts of the Government to bring it within the reach of all.

Of the users of quinine he says, "But, alas, they do not know what harm they do themselves! Quinine is thoroughly unsuited to our constitution; it checks fever no doubt, but poisons the whole system and ruins health and shortens life."

To give these views some appearance of truth he has the impudence to quote certain European authorities, this needless to say he does in the most misleading way, and the opinions thus travestied are the more dangerous as they are lies with a foundation of truth.

Thus GARROD is quoted as saying, "In large doses, it paralyzes the heart causing convulsion and death." Above the name of Dr. STILLÉ we find, "very large doses may produce blindness." These are samples of the way in which these impostors turn the sayings of others to their own advantage. It is infamous that anyone should travel on such dark and dishonest paths to the ruin of his fellow-man.

We have in quinine a drug recognised by the whole scientific world of medicine as of well proved efficacy in the treatment of malaria; and here we have a Kaviraj trying to rob his country-men of its benefits, and boldly proclaiming all over India that it causes blindness, convulsions and death.

The pamphlet we are discussing appeals to the more ignorant classes, how are they to distinguish between the true and the false?

In all quack productions there is a class of advertisement which verges upon, if it does not overpass, the boundary line of morality and indecency. "The Ayurveda Sangraha" is no exception. "Nervous Debility" stands out prominently and a medicine bearing the name "Ratihilasa" is represented as a certain cure. We read as follows "Excessive indulgence, etc., etc.; drinking, and many other irregularities of a similar kind . . . bring on nervous debility and finally loss of manhood." Further on, "This medicine within a short time removes debility, nervous prostration, premature failure of power resulting from excesses and indiscretions in early life."

We are told that "The great deity Shiva was the discoverer of this efficacious remedy."

"Samanaatha Baza" we learn, is also "a great Shastri medicine for Spermatorrhoea . . . It diminishes involuntary seminal discharges, it has the most potent aphrodisiac power."

"Amritprasha Ghrita" is represented as another cure for nervous debility. "Pranaba Ghrita" is a "specific for diseases of Indigestion." "It revives the languishing and drooping spirits of the debilitated and makes conjugal life happy." It works miracles the author says, "in the most efficacious and given up cases of gonorrhoea, etc. etc."

Aggravate come across some stuff called Makaradiwaja which appears calculated to do almost anything. It is said to be a compound of gold, mercury and sulphur and to combine in a truly miraculous manner all the virtues which eager imaginations have ever ascribed to each of the separate ingredients. We are not surprised to learn that it is represented to cure debility, typhus and typhoid fever, gleet, gonorrhoea, complaints of women after delivery, weakness of the brain, catarrhal complaints, whooping cough, etc. It is harmless as mother's milk to the new born babe in one column, and stands out as a potent aphrodisiac in the next.

Another somewhat anomalous compound is "Sanjiban Khadya or Infants and Invalid's food." This we read "dissolved in diluted cows' or goats' milk is the best substitute for mothers' milk." It may be given to infants "even when they are on the mother's breast," yet at the same time the wonderful food is said to be highly efficacious in such a jumble of diseases as indigestion, acidity, liver complaints, spleen, fever, gonorrhoea, hæmorrhage, consumption, asthma, diseases of the ear, kidneys and mouth, nervous debility, depression of spirits, diseases of women, leucorrhoea &c.

The state of the compiler's brain at this point appears to have got as mixed and marvellous as many of his wonderful quack remedies.

In the questionable class we have the "Shivada Batika" advertised as a specific for involuntary emissions.

Of course we find special remedies devoted to the diseases of women, and we have no doubt that many have been foolish enough to respond to the plausible advertisement of Mr. SEN GUPTA. We need not enter into particulars about them, sufficient to say that like the rest they undertake to cure the most extraordinary medley of diseases and to be infallible; which is alone sufficient to stamp them as cruel and dangerous lies wantonly spread abroad to prey upon the weak and ignorant.

No list of quack medicines would be complete without absolute specifics for consumption, epilepsy, syphilis, cholera, and here we find them in plenty.

But of all the wonderful things mentioned, we think the palm is borne off by the "Siddha Makaradiwaja" "This peerless panacea," we are told, "descended from heaven," "the great god Shiva presented it to the Siddhas," and the author states that, "It is the highest compensation balance in the gigantic and most intricate machinery of the human organism; so that a man never experiences the failure of nerve power even when he celebrates his centenary. It is the only solace of the dying and the decaying."

It is difficult to believe that advertisements of the kind we have been reviewing, can appeal to or mislead any one; yet it is not only the ignorant who fall into the hands of swindlers of this description. It is impossible to gauge the weakness and credulity of human nature when tormented and exhausted by sickness; anything that promises relief, no matter from what quarter the promise comes, is eagerly sought for, and it is the crowning opprobrium and crime

of these advertising quacks that they try themselves out to deceive and betray these sufferers in their distress. What it should be possible to do so with the sanction of the Government of the country is a disgrace to modern civilisation.

It only remains to bring to notice the names of a few medical men who have been guilty of unprofessional and infamous conduct in presenting testimonials in favour of these quack remedies, as advertised and duly acknowledged by Mr. SEN GUPTA in his "book."

The first name we come across is that of GOPAL KHANDRA MUKERJEE, B.A., M.B., Medical Officer, Katihar, next JOGENDRA NATH GHOSH, Assistant Surgeon, Teacher of Midwifery, Campbell Medical School, who writes, "My dear NOGN, The 'Mahamash Tulla' which you have sent for my use, wonderfully acted me, (sic) please send per bearer one phial of the same and oblige."

We have from time to time said a good deal about the standard of education in the Indian Medical Schools, if this is a fair specimen of the teachers, what must the students be like? It certainly does not speak well for the Campbell Medical School that the teacher of Midwifery should express such a partiality for quack remedies, and we trust that the attention of the authorities will be directed to the matter.

—:—

THE THIRTIETH ANNUAL REPORT OF THE SANITARY COMMISSIONER FOR BENGAL FOR THE YEAR 1897.

DISEASE AND DEATHS.

THE Bengal Sanitary Report for the year 1897 is very like its predecessors, a volume of considerable size. It contains 200 and odd pages and a portentous array of figures; the labour in compiling it must be enormous, and it is no fault of those engaged in the task if the result is distinctly disappointing.

An abundance of figures; a few more or less obvious or plausible explanatory notes; it passes muster, and is even accepted with flattering terms by the non-professional critics of the government to which it is addressed. The Sanitary Commissioner heaves a sigh of relief and the fruit of his labours is discussed with due solemnity by half the lay press of India.

We yield to none in our estimation of the immense value of statistics, when they are accurate in all the particulars in which statistics of disease should be accurate; but for masses of figures, which in most cases do not even claim to be accurate and which are often far from being even approximate, we have no respect at all. Of such figures the Report before us is mostly compiled.

It is obvious that all comparisons, deductions, and inferences drawn from such figures must be misleading, and that to take them too seriously is to fall into a grave error.

This report is of course compiled from the figures and reports sent in by the Civil Surgeons of the different districts, and this being so we should like, and indeed expect to see considerable prominence given to the opinions of these officials. In this we are disappointed for their opinions are rarely quoted.

It is only natural to presume that the civil surgeon is the best authority upon the health conditions of his own district, the unusual prevalence of disease, or the reverse, and the causes of increased or lessened mortality &c; and it is also natural to presume that had any of these officials communicated anything of importance or

of inspection on any of these points, that the Sanitary Commissioner would only too gladly have availed himself of the opportunity of giving it prominence in his report.

The absence from the Report of any interesting communications of the nature indicated inevitably leads us to the conclusion that the Sanitary Commissioner received but little assistance from the different civil surgeons, and that but little attention was paid by them to the various intricate problems relating to disease amongst the native population of Bengal.

We can safely say that, for all the light it sheds upon the different diseases which prevail in Bengal, their nature, origin, cause, and effects, the Report might just as well have never been written.

The Sanitary Commissioner in his office is bewildered by a complex labyrinth of figures which he is called upon to explain and elucidate. In his desperation he has hit upon three clues, (1) the famine or scarcity, (2) the short rainfall of the previous year, (3) improper food due to famine or scarcity. These clues are in the most marvellous way made to answer every purpose and to overcome all difficulties.

We may pause here to notice the explanation which the Civil Surgeon of Faridpur has put forward to account for the excessive mortality from "Fever" which occurred in his district. He says. "It is not confined to any particular locality, but visits almost every homestead in the district, which abounds in numberless dhils and swamps. All the conditions necessary for the production of malaria are to be found here in abundance, and to these may be added another factor which is every year gaining ground. I mean the steeping of jute in every available pool or stagnant water. There is hardly a village, hardly a house which does not go in for this trade and the result is that not a village is to be found which is not surrounded by stagnant water of a very objectionable smell, thickened and turned black by repeated steepings of jute."

This idea is repeated, without comment, by the Sanitary Commissioner, so we are left to puzzle out as best we can why jute steeping should cause fever. It is hardly necessary to dwell upon the want of logic in a man who tells you that all the conditions necessary for the production of a disease are present, and yet adds another factor, the important thing is that he has started what he perhaps thinks, and what has certainly been accepted in more than one quarter as a new idea, that the steeping of jute is the cause of fever. But how?

Is it suggested that the people drink the thickened, blackened and offensive water? We think not, for the drinking of impure water is so often credited with being the cause of disease, that, if this was the idea, it would most naturally have come under the head of impure water supply and the jute only incidentally alluded to as the cause of the impurity; whereas it is distinctly stated that the jute steeping is the cause of the "fever." For the same reason we acquit the Civil Surgeon of putting the blame upon the saturated condition of the subsoil naturally brought about by the abundance of stagnant pools.

From the evidence of his report we believe that he attributes the excess of "fever" to some specific action on the part of the jute, some poison we presume which is set free by the process of steeping.

The disadvantage of having a professional Report criticised by a Civilian who is quite unacquainted with the technical subjects of which it treats, is well exemplified by the remark of the Officiating Secretary to the Government of Bengal on the above.

"This" he says "is a striking opinion. The practice to which unhealthiness and mortality are here attributed, is not peculiar to Faridpur, and the Lieutenant-Governor will be obliged if the Sanitary Commissioner will draw the attention of Civil Surgeons in all jute-districts to these figures, and invite them to consider the effect on the health of their districts of the practice in question."

The opinion is certainly striking, and the comment on it also, but only we venture to think from the crass ignorance displayed in them both.

The idea that the steeping of vegetable fibre was a cause of malaria is no new one, on the contrary it is so old that it has been almost forgotten, and its reappearance amongst us causes us a start of surprise, not unmixed with amusement.

A vast deal of ink and paper was wasted in thrashing out this very question years ago, and in France and Italy where the belief was once prevalent, it has so long been rejected and cast into the limbo of forgotten and discredited theories, that there appear to be people now who have never even heard of it.

We can sympathise with the Sanitary Commissioner and the Civil Surgeons of other Jute districts, in being called upon to discuss a question which was decided in the early half of the century.

VITAL STATISTICS.

The population of Bengal is stated to be 71,069,617. The birth-rate for 1897 was 36.94, and the death-rate 32.94. For the year 1896 the birth-rate was 38.03 and the death rate 34.17. Thus both the birth and death-rate were lower in 1897 than in 1896, the former by 1.09 and the latter by 1.23.

The decrease in the birth-rate, such as it is, is attributed to famine and scarcity which prevailed more or less generally from October 1896 to September 1897.

Now taking the 15 famine districts, as given in appendix V, we find that in five of them the birth-rate increased instead of diminishing in 1897, while in the four districts noted as scarcity districts, it increased in two and decreased in two.

If we compare 1897 with the average of the previous five years we find, that the birth-rate increased in 3 of the 15 famine districts and in 3 out of 4 of the scarcity districts, so that, however right he may be in his contention that famine was responsible for the lowered birth-rate, the figures are not quite as conclusive as they might be.

Owing however to the admitted inaccuracy in registration, the variation in the inaccuracy from year to year, and the large margin of error which presumably exists in the estimated population, we do not consider the matter worth pursuing seriously. We would on the contrary class the statistics in this Report amongst those which may be made to prove anything.

On the other hand it strikes us as being curious that a condition of famine and scarcity that is sufficient to lower the birth-rate, should at the same time be accompanied by a decrease in the death-rate.

In general, however, from the supposition that while famine and poverty may be prevented, an excessive their influence on the birth-rate, that which becomes a question of birth-rate the meteorological conditions are of prime importance.

The general lowering of the death rate was, we are told, due to the fact that the previous year 1896, was an unusually dry one.

Some places however did not conform to this rule, but on the contrary showed an increase in the death-rate, the explanation given is that such places suffered abnormally from Cholera or "Fever," the abnormal prevalence of cholera again is said to have been caused by the people having been refused to consuming improper and unwholesome food, in other words it was due to the famine and scarcity which led to such a necessity.

As compared with 1896 there was an increase of death rate in 6 of the 15 famine districts in 1897. And as compared with the average of the previous five years, there was an increase in 8.

The whole of the large and important question of the etiology of disease in Bengal appears to be summed up in the following bald and empty statement "It will be seen that the mortality from cholera, dysentery and diarrhoea and other causes was, as usual, much higher in towns than in rural areas, while "fever" was more prevalent in the latter. The crowding together of people in towns with its attendant evils, (and the absence of proper drainage and the want of good drinking water in rural areas, explain these facts."

This is the very A.B.C. of sanitation, the trite commonplace of the causation of disease. "It needs no ghost come from the dead to tell us that."

But he who desires further information need not seek for it in the 30th Annual Report of the Sanitary Commissioner of Bengal.

We will discuss some other points of interest in the Report in our next number.

THE DOCTOR AND THE STATE

Dr. ROBERT FARQUHARSON, M.P. Chairman of the Parliamentary Bills Committee in an address to a Branch Meeting of the British Medical Association spoke some encouraging words concerning the growing interest of the State in medical matters, and the awakening in the minds of the profession of its position and influence and of its duties to the State.

The subject is one which becomes more important from day to day and in which, to their own great benefit, medical men are becoming more interested. The time has gone by when the duties of practitioners were considered to be of a purely private character and strictly limited to such questions as might arise between their patients and themselves.

The medical profession has a great future before it, if not exactly in politics, at least in the conduct of public affairs. The great advances that have been made, the way in which medical science has spread its boundaries in every direction, demand that our leaders should be ready to, at times, quit the consulting room, and take their places in the assemblies which rule the country.

Medicine has now become an important part of the Statecraft, and no nation can afford to neglect the advice of its physicians.

"I must talk to you for a few minutes" Dr. FARQUHARSON said, "about public affairs, the relations of medicine to the State, and of us to it, of the influence we have or might have, and the value of a great association like this in binding us together into that compact harmonious whole, without which we can accomplish nothing."

"I am very glad to see that our great corporations and the General Medical Council are beginning to press forward in public life, and that they are now being consulted by State departments in matters of hygiene and social legislation. To our medical parliament has been entrusted the duty of framing regulations for the construction of a Midwives Bill. The College of Physicians spoke out with good effect on the subject of the terrible ravages of syphilis in India, and I understand that the vague and mysterious body, which attracts some awe-stricken attention under the name of the Privy Council is in occasional communication with our professional leaders. The Local Government Board ought to be the head centre of everything that concerns public health, but it is underpaid and undermanned, and its usefulness is seriously hindered by the comparatively subordinate position which it holds—and why the Home Office, which regulates little more than law and order and factory legislation, should have a full-blown Secretary of State at its head, whilst the bureau to which is confided all our sanitary legislation, all water questions, and the whole of local government should merely rank alongside the Board of Agriculture, and Dover House is an anomaly which fairly defeats my limited powers of comprehension"

"Our constitution is broad and democratic, we appeal to a wide constituency, and we have planted in every corner of the United Kingdom centres of light and leading, which should illuminate, and instruct, and convince. Out of the 35,000 medical men in these islands nearly 18,000 belong to the Association, and our Branches spread and ramify everywhere, from Calcutta to India. What an organisation this is for concentrating and co-ordinating the great body of force and influence which we might and do possess!"

Dr FARQUHARSON mentions that we are democratic. As things are at present the medical profession is of necessity democratic, we are a rising body fighting for our recognition, our proper position and share in the government of the country. We are fighting not only for our own rights but for those of others. We are fighting for the health and welfare of the people, that they may have pure water to drink, unadulterated food to eat, proper houses to live in, proper treatment when they are sick. We are fighting to preserve them from the ravages of epidemic diseases, and from falling the prey to the insidious wiles of unscrupulous quacks who trade upon their superstitions and ignorance.

In most of these contests we find ourselves opposed to time honoured prejudices and to often by the weight of the conservative capitalist.

No medical man who puts the interest of his profession before all else, can be anything but a democrat. Many it

is true persuade themselves that they are Tories or Liberals, but that it is the result of an inherited attitude of mind, the attitude that has long been accustomed to regard medicine as things apart, relegated to the privacy of the museum and having no connection with public affairs.

Medical men have only to open their eyes to see that this attitude is no longer in consonance with the spirit of the times. *Advances Medicine!* is the watch word we must all carry in our hearts.

Dr. FARQUHARSON shows us what we can do. "By our organised pressure," he says, "we can educate the public mind and force the questions in which we, as custodians of public health, are specially interested, well to the front, and give them a chance of being picked out from among their competing rivals for early consideration and treatment; and then each of us can do something in the way of missionary enterprise. For, unhappily, there is much to be done. Quackery is still rampant among us and smart people and 'society ladies' delight in irregular practices of all kinds.

From the Peculiar People to the nebulous metaphysics of the Christian Scientists and their appeals to the mesmeric hysteria of the weak and credulous is not a very long step, and cures and secret remedies still deplete the purses of those curious types of twisted intellects which our higher education seems to produce.

We want a Bill which shall make it illegal for anyone to treat disease for gain, without being a properly registered practitioner.

"But in order that we can more effectually carry out our crusade and permeate the public mind effectually with our views, it is above all things necessary that we should take some part in public life, even at the cost of a little personal and pecuniary sacrifice.

"There has lately been, I am glad to say, much more interest taken in the House of Commons in matters medical."

"Sixteen years ago Sir WALTER FOSTER discoursed eloquently about the political powerlessness of the medical profession, and I fear that things are not a great deal better than they were then, except that he and Sir Wm FAIRBANKS now sit on the green benches, and for the first time in the memory of man, a registered medical practitioner, in the honoured person of Lord LISTER, has entered the sacred enclosure of the "other place." What we have to do is, first, to learn our power and then to use it. Next try to agree among ourselves, study unity and concentration."

Such is the prospect which Dr. FARQUHARSON holds out and some of the advice which he gives, and we trust that such members of the medical profession will lay his words to heart.

THE LESSONS TO BE LEARNED FROM THE DECLINE OF THE PLAGUE IN BOMBAY.

THE decrease in the mortality from plague in Bombay city which set in about the middle of October still continues, and leads to the most hopeful expectations. The decline is steady and has now lasted for over four weeks, the daily death-rate has fallen to eight, and altogether, if there is no fresh awakening of infection, there appears to be every prospect of Bombay seeing the end of its third epidemic in the course of the present month.

The following figures show the gradual and steady falling of mortality.

		Plague deaths.
Week ending 4th October	...	243
11th "	...	240
18th "	...	150
25th "	...	109
1st November	...	75
8th "	...	62

From another source we find that for the week ending November 11th the deaths were still further reduced to 62. While the numbers of daily deaths returned was, Nov. 12,—10 deaths; Nov. 13,—9 deaths; Nov. 14,—4 deaths. Nov. 15,—8 deaths; Nov. 16,—5 deaths.

All this looks exceedingly well, and when compared with the two previous epidemics goes far to justify the brightest prognostications. The present epidemic, on the 15th November, was in its 22nd week, and the number of deaths attributed to it was 2,800. Each of the preceding epidemics raged for nine months and accounted for 20,000 and 22,000 people respectively.

It is evident that for some reason or other the present epidemic has aborted, but the reason for its taking this course is unknown. It began earlier in the year, and at one time the gravest fears were harboured that it would surpass in extent and severity its two predecessors. These fears have however proved groundless.

We have evidently much still to learn, and to unlearn also, about plague and its epidemics. That the cold season of the year was particularly suitable to its ravages was one of those things which our oracles and so-called experts were never tired of insisting upon. In spite of this, we have always maintained that this opinion was based upon insufficient evidence, that it was altogether unworthy of credence, and in fact it might be classed with that other idea, now perhaps obsolete, that plague never travelled from west to east but always in the opposite direction.

We have constantly shown that there was nothing to connect the course and spread of plague in this country with meteorological conditions, but still the dread of the cold weather hangs over all the responsible officials, and in Calcutta assumes the tangible form of an expensive plague establishment being kept up in anticipation of the expected and often prophesied cold weather recrudescence.

The experience of Calcutta and of the present Bombay epidemic are strong arguments on the other side. The so-called plague in Calcutta disappeared at the very advent of the cold season, and in Bombay, an epidemic

which has been the almost constant experience that plague is a very independent phenomenon and that whatever may be the form which governs the course of its epidemics, they are not to be fought by hot and cold weather theories.

The laws of plague have still to be elucidated and in the dark as we are at present we can only agree with those authorities who tell us that it runs a regular and predestined course, which all human efforts are powerless to check or perhaps even to modify.

We used to hear a lot about stamping it out. It was at one time a favourite catchword with all plague officials, they knew better now and the pet expression has departed from their reports.

The most vigorous action on the part of the Bombay Government failed to have any appreciable effect upon the previous epidemics, while it had the ill result of interfering with the social condition of the people and of wearing out their patience.

Now obviously enough when the most severe of the measures, which were considered an absolute necessity at first, have been abolished and while others have been modified and pared away to an almost invisible tenuity, the plague quietly takes it into its head to depart.

All these things are strange and inexplicable paradoxes to the modern sanitarian with his shibboleth of isolation, segregation and disinfection.

So let it be! In the future we may hope to know all things.

While Bombay city is settling down into a state of quietude, its commercial prospects brightening, and its people recovering from the reign of terror and beginning to forget that there is such a thing as plague at all, the same pleasant outlook is by no means general throughout the whole of the presidency.

The plague conflagration has spread southwards and in several centres its deadly fires burn with unabated fury. The returns show that in the week ending November 11th there were in Dharwar 2,940 cases with 2,374 deaths; in Belgaum to the North there were 1,398 cases and 988 deaths; further North again in Kholapore there were 820 cases and 599 deaths. These are the figures that are shown in the returns, but we have every reason to believe that they fall far short of what actually is the case. We hear rumors of deaths by the thousand and of whole populous villages being completely wiped out.

The figures shown in the returns are however grave enough, goodness knows, and there is every reason to fear that the coming years will continue to see the spectre of plague stalking triumphantly through the land.

DECREES AND NOTICES

PUBLIC NOTICE

WANTED—JUSTICE IN BENGAL

1. **WANTED.**—Fair Trade in Medical Journalism. The Bengal Government subsidizes and supports the *Indian Medical Gazette* and thus misuses public money. Public protest has failed to stop this injustice. The *Indian Medical Record* has flourished for nine years without State support and has won the confidence of the medical profession. The *Gazette* has struggled on for 25 years with the aid of public funds. Comparison of subscription lists will prove these facts. The Bengal Government is guilty of injustice in this matter and it is hereby declared that this **NOTICE** will continue to appear in this form and in this position until Sir John Woodburn, the Lieutenant-Governor of Bengal, puts an end to this disgraceful and iniquitous system of State subsidy to the *Indian Medical Gazette*, which is owned by a private trading firm.

2. **WANTED.**—For the Medical College of Bengal in Calcutta, a fully qualified Surgeon and Teacher of Surgery, to occupy the position of Surgeon to the Calcutta Medical College Hospital and Professor of Surgery to the Calcutta Medical College. The aspirant should be a tried and experienced practical surgeon, well versed in all the lore of ancient and modern surgery, and be thoroughly capable of teaching a large class of students (who pay the Indian Government for their education) the following subjects:—General Science of Surgery, Surgical Anatomy, Surgical Pathology, Practical and Operative Surgery, and Clinical Surgery.

NOTE.—Certain members of the Indian Medical Service, whether they be qualified or not, will be favourably received by the Chief Secretary to the Government of Bengal, but it is specially notified that all other applicants outside the service of Her Majesty's Government in Bengal or in India, must be really and truly qualified.

This **NOTICE** will stand unchanged until the Bengal Government removes the present incumbent of the chair of Professor of Surgery (Mr. R. D. Murray M.B., who studied modern surgery in 1875, vide *Englishmen*) and till the Bengal Government does its honest duty by providing the students of the Calcutta Medical College with a proper Teacher of Surgery.

THE RAILWAY MEN'S PETITION TO THE DOMIOLLED GOVERNMENT OF INDIA.

THE FOLLOWING IS THE FOLLOWING LETTER TO THE EDITOR OF THE RAILWAY MAN.

Sir—My attention has been drawn to a reference made to me in your journal of the 10th October 1903, in which it is stated that I have been asked by an association or society of railway employees in India, to become their president, and some difficulty is expressed that I should link myself to a body that does not aim, in the highest and truest sense, at the advancement of the Cause of the European Railway men domiciled in India.

I beg to state most frankly and unreservedly that my political principles are based on the strict and just observance of that notion of British honesty and impartiality "A FAIR FIELD AND NO FAVOUR."

I recognise with deep regret that the Government of India has flung this guiding principle of true and righteous government to the winds in its dealings with the Domiciled British and European Community and its descendants in India; that the policy of the India Office in London and of the Supreme Government of this country, has evinced the most cruel and barefaced prejudice towards this important and ever growing community, inasmuch as the Government is making their struggle for existence more difficult every day, by the creation of disparaging and invidious differences in the market value of their labor as compared with labor imported from England in the various avenues of State-paid work in this country, and by the daily increasing, though absolutely unnecessary, importation of every kind of labor from England. The Government of India has heard the bitter cry of the children of Europeans in India for bread, it has read their earnest and reiterated appeals for the just redress of wrongs through their representative associations, it has had these prayers forced upon its attention in the audience chamber of its fountain head of power, the India Office of London, that stronghold of official Anglo-Indian prejudice and despotism, but to one and all of these attempts to evoke its exercise of justice, the Government of India has been either callously and contemptuously indifferent or only pharisaically sympathetic.

I bear this testimony to the shame of the British Indian Government. I do so with a burning sense of indignation at the way in which my people in this country have been treated, and I do it with the express object of arousing a sense of solemn responsibility in the hearts and minds of the Domiciled European Community of India, for the future well-being of their children. I do so because the Government of India has been indifferent to the cry of our people, for the sole reason that it believes with Lord DUFFRIN, THAT WE ARE NOT UNITED. Lord DUFFRIN in his famous minute on "the Question of forming Anglo-Indian Regiments in India" wrote:—the question of the difficulty of raising Anglo-Indian Regiments is not one as to the physical fitness of this community to serve as soldiers. It is one of political significance. DIVIDED as it now is, the Government can afford to treat its requests with indifference, but LET THEM ONCE BE UNITED, AND THEY WILL NOT BE REJECTED. These words form the keystone to the socio-political emancipation of the Domiciled British and European Community of India. This same advice was soundly in my ears by a few eminent politicians in the British House of Commons last year.

The natives of India have succeeded in obtaining a just recognition of their political position by persistent agitation and Christian witness. Our people have adhered to the old fashioned red-tapeism of forwarding cringing appeals to

Government. But "that respectfully begged" and the Government gave the same old official cold-hearted reply "It cannot interfere."

Our people cry that handover to the UNION, which being read might make "DUFFRIN'S NOT DUFFRIN" and our demand must be A FAIR FIELD AND NO FAVOUR. Equal rights for the Imported Britisher and for the Domiciled Britisher and his descendants in India. We ask that merit and ability be the only criterion for employment and promotion and that these be gauged by their only true and just test, OPEN AND IMPARTIAL COMPETITIVE EXAMINATIONS. At present, nominations and selections, entirely in the gift of the India Office or of the Supreme and Provincial Governments of India, backed by that curse of all despotic Governments, INTEREST, command the portals of every service and of every avenue of labor in this land. We demand that this autocratic system, which is warping the loyalty of the Domiciled British and European Community, disgracing the British Government, as well as ruining India, shall cease. We demand that wherever British or European labor is required in the Indian market, such talent, whether imported or locally trained, shall be treated on TERMS OF EQUALITY, and that MERIT SHALL BE THE ONLY TEST OF DIFFERENCE in the value of one commodity over the other. If this principle be not accepted and acted upon, there is no necessity for higher education in this land, and the domiciled Britisher and his children must for ever remain the bondsmen of their imported kinsmen. The very idea is sufficient to cause a revolution.

Let Railway men all over India once realise that UNITY OF PURPOSE, UNITY OF EFFORT, AND UNITY OF ACTION are the means, the only means to bring about a successful and satisfactory termination to all their disabilities and grievances, an era of peace, contentment and prosperity will then and not till then dawn on their destiny. It is the old story of the exercise of a conscious possession of power, used righteously and with a righteous end in view. Everything must be done constitutionally, but let there be a firm, manful and dignified exercise of this real and conscious power, such as the employees of the Domiciled British race possess, and those in authority will soon realise its meaning and its force.

These are my sentiments and I am prepared to stand by them and defend them, and to exercise my humble talents in the promotion of the Anglo-Indian Cause on the principle of EQUALITY GAUGED BY MERIT and actuated by a true and unflinching British spirit of FAIR PLAY.

In conclusion let me urge every Railway man, no matter what his position, to at once cast aside all fears and face the fight before him in perfect and absolute UNITY with his comrades. Let no man be a traitor to the RAILWAY MAN'S CAUSE.

Yours faithfully,
JAMES R. WALLACE, M.D., F.R.C.S.

50, PARK STREET, CALCUTTA, 24th November 1903

TREATMENT OF TUBERCLE OF THE LUNG BY THE INJECTION OF NITROGEN GAS INTO THE PLEURAL CAVITY.

FROM a letter which appeared in the *British Medical Journal*, 22nd October, by Dr. STUART TIDY headed "A visit to the Hospital of San Giovanni at Turin" it appears, that what was described by Dr. MURPHY of Chicago at the Meeting of the American Medical Association (Denver, Colorado, June 10) as a new method of treating pulmonary tuberculosis, has been employed by Professor CARLO FORLANINI of Turin for the last ten years.

"On entering the laboratory," Dr. TIDY says, "I saw an apparatus for the preparation of some gas, and on asking the

professor its use, he said, "It is for the purpose of injecting into the pleural cavity, and thus destroying the paratyphoid in unilateral tubercle of the lung." What results have you? I asked. "Gummatous" he replied, "but not well"; he replied.

And supposing they are cases of pure tuberculous infection? I asked. "Gummatous" he replied.

The professor added that he had perfected this method for ten years.

At the meeting above referred to, this method of treatment was dealt with at some length by Dr. MURPHY.

He drew an analogy between this method and the method of treating tuberculous in other parts of the body. And of this analogy rest is the keynote.

In bled knee, for instance, tuberculosis of the knee, we set at rest the diseased articulation. With rest new tissue is formed and the disease germs enclosed in a case from which they cannot possibly escape. We sustain the life of the healthy tissue to repair the destructions of the diseased. While the knee is at rest the tissue forms more rapidly, and gradually the diseased part is made by Nature to disappear. Subjects in the dead house will prove that this theory holds good in the lungs where tuberculous germs have begun an attack. Necropsies have revealed numberless persons whose lungs were once affected by the bacillus, but Nature has cured her ailments alone.

How can we put one lung at rest, to sleep as it were, put it off duty for a time, while we allow that rest to form the new tissue needed by Nature to smother the bacilli? We have the best pathological evidence that it will repair. Surgical operations prove that.

Pleurisy is a sequence of tuberculosis in 83 per cent. of the cases. Out of 146 cases of an eminent surgeon, but 4 were fatal where the operation of empyema was performed. Pleurisy is a curative and reparative to tuberculosis. Tuberculosis is repaired by pleuritic effusion. We must treat the lungs as we treat tuberculosis in other parts of the body. The lung has the greatest capacity of repairing tissue. How, therefore with such facts known, can we aid and assist the lung in its efforts to encapsulate? We must put it in a condition to build up a collar around the diseased part. That is accomplished by Nature in three ways. First, by removing the ribs and allowing a contraction of the chest over the diseased part, secondly, by opening the chest wall and rendering aid by direct injection into the pleural cavity. We inject into the pleural cavity some substance not poisonous that will remain for a long time, some substance not easily absorbed. The third method is by opening and allowing the chest wall to sink over the tuberculous cavity. I have operated by the latter method, and found that the cavity was in time obliterated. These skiagraphic views that I have were taken from a patient from November to April, at which time it will be noticed by the views the cavity has entirely disappeared. The method with the admission of air has the same curative effect as allowing the collapse of wall. The injection of a gas or fluid into the pleural cavity, nitrogen gas preferred, is the ideal treatment for tuberculosis of the lungs. The gas being very slowly absorbed may be allowed to remain for months without injury to the patient, until the disease is cured.

One of these skiagraphic views shows a patient whom I operated upon some months ago. The curative effects of the operation are most apparent. After the injection of the nitrogen gas the patient suffered a slight dyspnea, but immediately upon leaving the table remarked that he felt better than he had for months. He refused to take to bed. On the first night after the operation he was enabled to sleep well, something he had not enjoyed for months. That irrigating and annoying cough prevalent among consumptives is doubt-

fully relieved by the injection of the gas into the pleural cavity. In some experiments, the night has been very comfortable. With the operation, which is a simple one, there is no pain and no discomfort. There is no difficulty in performing the operation. There are some risks of course, but none greater than the average surgeon encounters in ordinary operations. It may be said that there are possibilities that the gas will not enter the pleural cavity when there are adhesions. These adhesions can easily be removed. The pathology upon which this is based is the quiescence of rest.

With this method of treatment one may attack the earliest stages of the disease. It may be caught in its very incipency when the patient enjoys fairly robust health and will not be endangered by any shock that may occur.

In most cases artificial pneumothorax, the operation applying to the injection of nitrogen into the pleural cavity, will be the most available operation. The arguments for it are the methods of repair. The prominence of tuberculosis of the lungs is due to the opportunities for infection and not to lowered resistance. Rest favors resistance, and by the injection of the nitrogen the diseased lung will be allowed to rest. Any functionary useless organ is the seat of connective tissue overgrowth. Thus, as the lung is a functionary organ at rest, the tissues rapidly form and enclose the destructive germs in a prison. The connective tissue overgrowth is the process by which tubercle is walled off.

The cessation of the expansion of inspiration causes the fibres to arrange themselves as is best suited for walling. The collapsed tissue shuts off blood and lymph channels, which are routes of infection. Connective tissue grows best in areas of poor blood supply. Tuberculosis long remains a local disease. The views of STRAUSS, KÖNIG, CABOT, and RÜNHENIG substantiate this. The conclusion is irresistible that in most cases of tuberculosis as we see them this is the operation of election.

TREATMENT OF ANEURISMS BY SUBCUTANEOUS INJECTIONS OF GELATINE.

M. LANGEREAUX communicated in his own name, and in that of M. PAULESCO, at the French Academy of Medicine 11th October 1898, observations on two cases of aneurism of the arch of the aorta, and one case of aneurism of the right subclavian, which were cured by subcutaneous injections of gelatine.

The solution employed by M. LANGEREAUX contained 2 grammes of gelatine in 100 grammes of normal salt solution. Of this solution he injects 200 to 250 c.c. at a time, and repeats the injection as often as necessary to procure the disappearance of the aneurismal tumor.

While these injections are of undoubted benefit in aneurismal aneurisms, the case is different with fusiform dilatations involving the whole circumference of the vessel, here there is no slowing down of the blood current and as this is one of the most indispensable conditions for the deposition of fibrin, the gelatine injections are of no use.

M. NUCHARD said, I have seen a man, without a history of syphilis, in whom a large aneurismal tumor of the aorta completely disappeared after 15 injections of the gelatine solution described by M. LANGEREAUX.

On the other hand, with the same injections, in a case of tubercle of the lung, I have rapidly checked hæmoptysis which had previously resisted all treatment. These cases appear to me to be also suitable for treatment by subcutaneous injections of gelatine.

At the same time I do not think that these injections, which are rather painful, are absolutely free from danger, I would particularly recommend that they should not be used in

considerable aneurismal artery opens close to the aneurismal mass.

On Foraminata removed.—In connection with the communications which Dr. LAROUSSEAU has just made, I would like to draw attention to a common source of error in the diagnosis of aneurism of the aorta. I remember once seeing in consultation with PARRA, a syphilitic case which presented every sign of aneurism of the aorta, particularly remarkable was a considerable zone of dulness at the base of the sternum.

I put him on a strong anti-syphilitic treatment which cured him in three weeks. In this case the appearances were not caused as PARRA and I thought by an aneurism, but by extensive gummate in the neighbourhood of the aorta. I have had occasion to observe the same thing in several other cases.

FUNCTIONAL ACTIVITY OF THE KIDNEYS

M. CHATEL (d'Evian).—In the physiological state it is known that a man passes in the 24 hours, a quantity of urine in excess of the liquid he has drunk.

In the 12 hours of the day (from 7 A.M. to 7 P.M.) he secretes two-thirds of the total urine of the 24 hours.

After the mid-day meal, he passes in two hours the total quantity of fluid taken as drink; the density of the urine then falls below 1010. The same does not happen after the evening meal.

A local disease does not affect the manner in which the kidneys act, it only becomes modified when the general health is affected by infection or innervation.

When the mode of action of the kidneys becomes re-established either spontaneously or under treatment, the equilibrium of the organism is restored and drugs are not required.

I think the knowledge of these facts interesting because perversions of the functions of the kidneys begin and creep on in a latent manner.

A SHORT HISTORY OF THE HYDERABAD MEDICAL SCHOOL

DR. KHAJA ASHRAUF *Chief Surgeon of SURIAPETT, NALGONDA DISTRICT, of Hyderabad* writes as follows in the *Deccan Medical Journal*.—In former days, English medicine was not practised in Hyderabad. Till the year 1257 Hijri, there were only Hakims, and they practised the Yunani system of medicine. The best known amongst them were Hakim-ul-Hakims, Gulam Hussain Khan, Hakim Raza Ali Khan, Hakim Shafai-khan, Hakim-ud-Dowla, Hakim Munna Jan, Hakim Hafiyat Talub Khan, Hakim Mualih Khan, Hakim Muhammad Zama Khan, Hakim Syed Sahib, Hakim Masih-u-Zaman Khan, Hakim Ahmed Yar Khan and Muhl-ud-Dowla. These Hakims were no doubt clever men, who were able to diagnose cases successfully and some of them even had access to the then Nizam. They were all outsiders who had come to Hyderabad and had gained honor and wealth here, but considering the population and the large number of patients requiring treatment, it was impossible for these few Hakims to attend all those who required medical assistance. The result was that the poorer people did not receive the attention that the nature of their illness demanded, and consequently had to bear much unnecessary suffering. As a last resort, they had recourse to witch-craft, magic, &c.

About that time a peon in the service of Mr. Deighton, Talukdar, who had worked in his hospital and had thus become acquainted with the use of Jellip and Quinine and the doses in which they were to be administered, set himself up as a Medical Practitioner. These medicines having relieved a number of the sick to whom he had given them, his reputation soon spread among the people as a Physician, in fact as a Specialist, and he made heaps of money.

In the year 1257 Hijri, His Highness the late Nawab Nasir-ud-Dowla Bahadur suffered from some urinary complaint and diabetes; and the Yunani treatment gave him no relief.

One day General Hastings Fraser, who was then British Resident at Hyderabad, had an audience of His Highness and observing that His Highness was dull, enquired after his health. His Highness told him that he was suffering from urinary complaint and, remarking incidentally that he had heard the English system of treatment praised a great deal enquired if there was a remedy for his malady. General Fraser replied that if His Highness was pleased to order, he would send a Doctor at once. His Highness consented to it, but on condition that English medicines should not be administered in either a solid or liquid form. His Highness related the story of Hakim Alvi Khan Dehlavi who was taken to Persia by Nadir Shah. A few days after their arrival there, Nadir Shah had a severe headache, and failing to obtain relief from his own medicines, he asked the Hakim to treat him, but objected to the use of medicine internally or externally. The Hakim prepared a *jam* and by means of it made him inhale some kind of medicine which removed the head-ache. "But I" concluded His Highness "will not even inhale any English medicine."

However, according to the Resident's wishes, Dr. Maclean, the Residency Surgeon, duly presented himself at the Palace, and without giving His Highness any medicine, so regulated his diet that in three months' time he was completely cured. His Highness was exceedingly pleased, and ordered that a school should at once be opened to teach English Medicine and Surgery to natives of Hyderabad.

Accordingly in 1216 Hijri, a School was started near the *Tope ha Nancha* (opposite to the Fatah Maidan) with the undermentioned pupils:—

Mahomed Yakub, Mahomed Bakir Ali, Gulam Hussain, Buran Shareef, Khwajah Ashraff, Mahamud Hussain, Gulam Jilani, Syed Nur, Gulam Muhammad, Atakhan, Pir Khan Faizulla Khan, Muhammad Molana, Molana Fakir Sahib, Vazir Ali, Shafai Khan, Mirza Ali, Muhammad Ashraff and Shams ud-din. When this school had been in existence for about six months the Prime Minister by order of His Highness visited it, and after examining the pupils, gave prizes to the deserving ones. After this, the school became more popular, and the Government was greatly interested in it. In a period of eight years, nine pupils passed and were declared qualified to practice medicine. They were appointed as Surgeons. Dr. Muhammad Ashraff and Hakim Faizulla Khan being the two first to be appointed in the City. The late Sir Balak Jung (the I), by his encouragement, gave great impetus to this school, which during the last 20 years has made such rapid progress, that it has sent out qualified Doctors to the remotest corners of His Highness the Nizam's Dominions.

It is unnecessary to mention all the progress that has been made during the beneficent rule of His Highness the present Nizam. It is one of the results of his peaceful reign that we are able to day to give expression to our feelings of gladness.

HOW THE PLAGUE WAS FOUGHT IN AN ENGLISH VILLAGE IN THE SEVENTEENTH CENTURY.

WE take the following from the *British Medical Journal*.—"Dr. GORDON SHARP, of Leeds has sent us the following interesting account of the manner in which a Derbyshire clergyman fought the plague in the seventeenth century. The village of Hyam (pronounced Bam), sometimes called the "Plague Village," is situated in Derbyshire, six miles north of Bakewell, and twelve from both Sheffield and Bux-

collected his entire year's bill on a certain market day in summer, getting perhaps five or six pounds from the larger farmers, but only as many shillings from the poorer artisans.

HOW GOLD DISSOLVES AROUND

HAS been a question that has worried the world for centuries and many and wild are the theories how the gold was washed out of the original rock and deposited in river beds and gulches in larger nuggets than those found within the parent rock; but this improbable attrition and reunion theory has been knocked on the head by a Slavonic chemist, named ZERINSKY (St. Petersburg) who made formaldehyde react on a slightly alkaline solution of a gold salt and found that when the product was distilled, gold was obtained in a colloidal condition in which state it was freely soluble in water from which it could be precipitated by adding sodium chloride to the solution. Colloidal gold probably exists in quartz rocks from which it washed out by the rains into the rivers to be deposited in the river gravels, wherever there is anything containing sufficient salt to cause its precipitation, and the fine particles by adhesion coalesce by molecular conglomeration to form a nugget whose size increases in the course of ages.

FOREIGN BODY IN THE BLADDER

FRANK SURGICAL SOCIETY.

M. PROCTOR made the following remarks on a case reported by M. ROCHARD relating to the supra-public extraction of a hair-pin which a young girl of 14 had introduced into her bladder.

M. ROCHARD had in the first instance made two ineffectual attempts, under chloroform, at extraction by the natural passage after dilatation of the urethra.

On three occasions I have had occasion to intervene in analogous cases, and it is my opinion that we must give up the hope of obtaining satisfactory results by direct extraction after dilatation of the urethra.

In cases of this kind it is, in my opinion, better to operate through the vagina, but in cases where the vagina is small and the hymen intact, as in the case under consideration, I believe that the supra-public method is indicated.

DEATH OF DR. WILLIAM PEPPER.

Is reported from California from angina pectoris. Nothing could have thrown Philadelphia into more profound grief than the news of the demise of this gentleman who had done more for that city than any man alive. He was one of those few men who was never idle and besides taking a prominent part in raising the standard, of medical education he built, and perpetually endowed the clinical laboratory as well as urged the state opening of laboratories of anatomy and hygiene and museums also for the better understanding of men and disease. He was for many years Professor of pathology and, when the Pennsylvania University bell tolls for class many a head will bow in grief over his memory.

HOURS FOR BIRTH AND DEATH.

FROM an analysis of 36,815 births at Rome between 1894 and 97 and of 26,000 deaths between 1886 to 1890, ROSEBY (*N. Y. Med Jour.*) finds that the greatest number of births takes place in the early hours of the morning, when carbonic acid which is an excitant of uterine contraction is more abundant than at other times, and that the greatest number of persons die in the early hours of the afternoon when the sympathetic, which is more active at night, is not controlled by the brain and spinal cord.

LONGEVITY STATISTICS.

BRENA CORREIA who was born in Africa in 1749 and is now residing in Rio de Janeiro, is the oldest person living, whose age has been proven, and next to him comes a coachman

of Moscow and WILLIAM URSIN of Stockholm with 140 years a piece. In England there are 146, Ireland 272, Scotland 44, Germany 73, France, 312, Sweden 10, Norway 25, Belgium 4, Denmark 2, Spain 401, and in Servia 17 persons who have passed the century mark, and it is curious to note that more persons over 100 years old are found in mild climates than in the higher latitudes.

WANTED—SYSTEMATIC RESEARCH BY REGULAR METHODS.

SAYS *Indian Engineering*:—Much of what we in British India do is fragmentary work, put up haphazard as the exigencies of the moment dictate, without the least effort to bring the various departments into line or into relation with each other. We plant a Bacteriological Laboratory in one place, Chemical Examiners in another, and we talk of establishing a research university in a third. We bring out experts at long intervals, and then pigeon-hole the reports which everybody admits to be master-pieces. We send Civilians to be trained for Directorships of Agriculture and Army Doctors for Chemical Examinerships and mint assaying. No doubt there are always good reasons for each of these steps; but the whole strikes us as wanting in continuity of texture, system, and plan.

OUR WORTHY D.G.

SAYS the *British Medical Journal*:—Surgeon-General R. HARVEY, O.B., D.S.O., M.D. Bengal Establishment, has been appointed Director-General of the Indian Medical Service and Sanitary Commissioner with Government of India, in succession to Surgeon-General J. Cleghorn, O.S.I., M.D., retired. Surgeon-General Harvey entered the service as Assistant Surgeon, March 31st, 1865, and became Surgeon-General April 1st 1895. He served with the Boontan Expedition in 1865-66 (medal with clasp); with the Loosha Expedition in 1871-72 (clasp); with the Hazara Expedition in 1891 as Principle Medical Officer (clasp); with the Mirauzi Expedition in 1891 under Sir William Lockhart as Principle Medical Officer (mentioned in despatches, D.S.O., and clasp); and with the Isazai Expedition in 1892 as Principle Medical Officer.

THE DECCAN MEDICAL JOURNAL.

WE gladly accord a hearty welcome to our newly started contemporary, *The Deccan Medical Journal*. The first number has just come to our hands and it does credit to its Editor and printer. We find no date on this number so we cannot identify the period of birth of our Deccan friend, but we expect to see many issues following the first and we wish our contemporary a long and useful life and much prosperity.

SHORT ITEMS AND PERSONALITIES.

The "Professor" of midwifery in Calcutta attends the Eden Hospital for a few minutes daily. He gets a huge state salary, and spends the bulk of his time in private practice. How much clinical gynecology and obstetrics does he teach? Was SIR JOHN WOODBURN charged a fee for publicly advertising in the daily newspapers the small number of successful abdominal operations performed by MR. C. H. JOUBERT, M.B. (ADMIRAL I.M.S.)

A meeting of the Council of the Indian Medical Association was held on the 28th November. A full report of the same will appear in our next number. Among the matters considered at the meeting was an important letter from the Government of India on the importation of doctors and nurses from England for plague duty in India, also the subject of Independent Medical Colleges and the inauguration by Government of a technical sanitary school and the institution of a degree in sanitary science by the Calcutta University.

Richards Military and Civil Assistant Surgeons, who have been in independent medical charge of districts, have not

been considered first-class officers for purposes of travelling allowance, a hardship which the Government of India has just recognised and remedied by ruling that in future these classes of officers will be entitled to travelling allowances at first-class rates. This concession will be much appreciated, and removes a hardship.

In the sad and untimely death of Military Assistant Surgeon E. J. Baptist of Madras, the Government of India has lost a most worthy and efficient Warrant Medical Officer. Mr. Baptist died on the 12th November 1898, and was only 42½ years of age. He was a frequent and valued contributor to the *Record* and this journal will ever hold his memory in high esteem.

Arsenic in wall paper causes much trouble. Hitherto the trade has been against green wall paper, but close investigation has proved the presence of arsenic in various colored papers. The best living rooms are those with bare or painted walls as no matter how free it may be from arsenic, wall papers are always injurious to health owing to the dust and disease germs they collect.

Dr. H. M. Whelpley has in his possession a number of artificial roasted beans that look remarkably like the genuine article but are made of clay. They were obtained from France where there is a pretty extensive business done in coffee berries that are made of clay moulded and colored to match the best genuine article.

Motor tricycles are recommended by the *British Medical Journal* for use of doctors in country practice. Petrol or rectified benzoline, which costs about a shilling per 100 miles, is the fuel used to attain a speed that can be regulated (by a small lever in front of the guide bar) to anywhere between 4 and 20 miles per hour on even pretty steep gradients, though a little pedaling is necessary to help the motor in climbing a very steep incline.

The Calcutta Municipality has been distinguishing itself during the past fortnight or so by allowing dust and dirt to collect in all the principal streets, inches deep, and then, just as people are going to office and about to come home again, flooding each street with water and converting it into a quagmire—a sort of death-trap for cyclists.

Professor Gerald of Halle says that if during the process of curing, tobacco leaves be steeped in a decoction of which the principal element is wild marjoram (*Origanum vulgare*), the deleterious effects of tobacco are avoided and the nicotine neutralised without altering the quality and aroma of the tobacco.

The following officers come out for a term of service in the Royal Army Medical Corps and are posted to the Punjab command,—Major Zimmermann; to the Bengal Command—Lieutenant-Colonel Carter and Captain Mansfield, and to the Madras Command—Major Oree, Captains Bullen and Buswell.

The "Professor" of midwifery in Calcutta declares to his female friends, that he and his "little assistant in Eden" will have their knives into the Editor of the *Record*. Our motto is the motto of the Wallaces, "aye ready." So come along Jobert, Stevens & Co.

Who does the midwifery in the Calcutta Eden Hospital for the poor European and Native patients who resort

there? Is it done by pupil midwives and pupil nurses? What is the septic puerperal mortality of this huge institution? Will Sir John Woodburn kindly enquire?

Until definite orders arrive from home regarding General Gore's successor as Principal Medical Officer to Her Majesty's Forces in India, General Townsend, Umballa District, will officiate from the 1st December next.

Captain A. Thompson, Royal Army Medical Corps, has been granted a gratuity of six months' pay, for the injury sustained by him in the execution of his duty at the Station hospital at Barrackpur.

Captain A. Anderson, I.M.S. Surgeon Naturalist to the Indian Marine Survey, proceeds from Bombay to Calcutta for two months to complete his description of the *echinoides* collected in the Indian sea.

"Give the Professor of Surgery a towel." This is how our modern teacher of modern surgery addresses his requests to his students, his unwilling followers, in the operating theatre of the Calcutta Medical College.

Fifty rioters connected with the recent outrageous assault on Dr. Ramasawmy Iyengar at Chikballapore on the 17th November, have been tried by the District Magistrate of Kolar and sentenced to imprisonment for six months each.

Dr. Weatherly, the Planters' Doctor, Darjeeling, and occasional poetical correspondent to the *Orissa Military Gazette*, committed suicide at 9 o'clock on Sunday, the 13th November. No reason is ascribed for this rash act.

Zinc is a metal that has been found in the human liver, ox muscle, hen's eggs, cat's liver, wheat, barley, beans and a few other vegetables; but the quantity is too small for remunerative zinc mine work.

The average brain of an intelligent European weighs 82.8 oz; but Dante's brain weighed 85.2 ounces, Schiller's 87.8, Kant's 99.0, Byron's 108.4, Gaviere's 109.8, and Rismarck's 112.1 ounces.

Wood spirit as a substitute for rectified spirits of wine is claiming a good deal of attention just now as a cheap and serviceable solvent where its toxic properties are not objectionable.

In spite of all precautions and the expenditure of vast sums of money, the plague continues to stalk through India. It has now attacked the Central Provinces, and has apparently established a firm hold there.

The Risle Plague has disappeared but "the band plays on" and the pipers have to be paid. Sir John Woodburn does not pay the "piper" and so he does not care a brass farthing, but the taxpayers of Calcutta do.

Dr. Pettifer, the special Plague Officer has had an increase of Rs. 100 per mensem to his salary, and his gari or carriage allowances have also been enhanced. For what?

Mr. E. D. Murray M.B. seems to have developed an acute attack of myopia since he has become "Professor" of surgery. People say he cannot see his friends.

It is rumoured that M. Haffkine will visit Bangalore to carry on investigations to ascertain if the plague there is different from the disease with which he is familiar

Mr. Chamberlain, as Colonial Secretary, has taken steps to establish a School of Tropical Medicine at the Seamen's Hospital, Albert Docks, London.

Lord Lansdowne has ordered the enrolment of a battalion of one thousand Chinese to serve at Wei-hai-wei under British Officers.

We are pleased to learn that Captain P. W. O'Gorman I.M.S., who is now on furlough in England, has passed the necessary examination for the D. P. H. Cambridge.

The hemlock plant grows wild in many countries; but it is strongest and most abundant in the active poisonous principles in Italy and Greece.

Foreign medical men may treat persons of their own nationality in Italy; but are liable to a penalty if they even give first aid to an Italian in a street accident.

It is now said that Colonel Taylor, R.A.M.C., who was in the running to succeed General Gore as P.M.O. in India, has been appointed in the Soudan.

The India Office has called for doctors to volunteer immediately for plague service in the Madras Presidency.

Surgeon General Oatherwood, R.A.M.C., to be Principal Medical Officer, Bengal Command, *vice* Walsh

Captain Maddox, I.M.S., is to be Personal Assistant to the Principal Medical Officer, Bengal Command, *vice* French.

Lieutenant-Colonel A. Deane, I.M.S., has joined his appointment of Inspector-General of Civil Hospitals, Punjab.

Lieutenant-Colonels Smyth, I.M.S., and Conry, I.M.S., both of Bengal, are permitted to retire.

The United States alcohol consumption in 1896 was 70,000,000 gallons less than in 1888.

WANTED—A European Medical Officer, with home qualifications and some years' experience in the treatment of coolies required for a large Tea Co. in Assam. Apply stating terms to Superintendent, care of "Englishman Office."

Defaulting subscribers to the Record are requested to send in their dues before the close of 1898.

Please send all communications for the Indian Medical Record whether for the Editor, Proprietor or Manager, to 50, Park Street, Calcutta.

ON WOUNDS OF THE ABDOMEN CAUSED BY BLUNT FORCE.*

STILL all the above mentioned symptoms, even when, as rarely happens, they are all found united in a single case, permit us to form only a more or less probable diagnosis.

It is only when characteristic perforation peritonitis is fully developed, that the diagnosis of rupture of the intestine is freed from difficulty, but then it is almost always too late.

Exploratory laparotomy undertaken as soon as possible after the injury, is the most certain means of obtaining an early diagnosis, its urgency cannot be denied in face of the unsatisfactory results which have followed the waiting plan. Exploratory laparotomy performed under aseptic conditions is almost without danger for the patient.

Of course the operation should not be undertaken in the presence of severe shock, the abatement of the symptoms of shock should be waited for. Slight shock however is no contra-indication.

Should it be considered dangerous to give an anæsthetic, the necessary opening can be made under local anæsthesia very well. It need only be large enough to see whether gas, fluid, blood, or fecal matter is present in the abdominal cavity. Should nothing be found, then in place of torturing uncertainty, we have without injury to the patient, our minds made easy.

Should the result be positive, then without delay anæsthesia can be induced and laparotomy be performed, by which alone we can hope to save the otherwise lost life of the patient, when there is a perforation of the intestines or a severe internal hæmorrhage.

In order to pursue this course with the best chances of a successful issue, the rule laid down by MADELUNG must be followed; that the physician called in to render the first assistance should with the least possible delay, place the wounded person under conditions where the investigation can be carried out in the best possible manner and with the least possible danger; as a rule this will be in the operating room of a hospital.

It is known that men have recovered from an injury which caused a perforation of the intestines under the expectant, i.e., the non-operative treatment, and the consideration of this fact has led many surgeons to oppose operation; but that was when the technique of laparotomy was not so fully developed as it is at present, and when those operated on almost all died in spite of the operation.

Statistics show how few cases of rupture of the intestines recover without operation. PATEY fixes the mortality of cases in which the stomach or intestinal canal is ruptured by blunt force, and where no operation was performed, at 97.5 per cent! And amongst the extremely few cases in which a spontaneous cure has taken place, how many have been included in which there was no actual perforation at all, but only a bruised condition of the intestine with severe symptoms?

The following combination of circumstances favorable for healing must moreover be present, the exudation of fecal matter through the perforation must be either very small, or absent altogether, the peritonitis must not suddenly develop into a diffuse septic inflammation, but must remain circumscribed, the perforation must not be too large, and must not be multiple; it must be quickly closed by neighbouring tissues, or by adhesions; such adhesions must be sufficiently firm not to be broken down by peristalsis, by collections of gas, or fecal matter, or by the movements of the patient; serious

*By Dr. Adolf Schmitt, from Münchener Surgical Clinic. (Specially translated from the *Munchener Medizinische Wochenschrift* for the *Indian Medical Record*.)

complications must be absent, such as wounds of the liver, spleen, kidneys, mesentery or omentum etc.

How seldom these favourable conditions are found in persons suffering from these injuries is evident from the enormous number of deaths, and by the small number of cases in which spontaneous cure results, without fecal abscesses, fistulae, eruption of pus into the bladder or rectum, knitting together of the intestines leading to symptoms of obstruction, in short to a variety of sequelae which in turn call for operative interference.

Under a non-operative treatment on the other hand, one can scarcely point to even a minimal number of cures.

Thus there are a certain number of cases which fulfil the above mentioned conditions, though this cannot be vouched for at the onset, and in these the administration of opium, ice, careful diet, and rest in bed may powerfully assist Nature's efforts to effect a cure. Should however a single one of the necessary conditions be wanting, all such measures are powerless to assist the onset of fatal perforation peritonitis.

The enormous dangers on the other hand with which the waiting treatment just alluded to is associated, are the very dangers which are avoided or proportionately reduced by an aseptic laparotomy.

By the earliest possible opening of the abdomen, is it alone possible to close the perforation and prevent further fecal exudation, to remove the intestinal contents that have already escaped and so diminish the danger of infection and finally to check possible hemorrhage.

Statistics also show that much better results are obtained from the operative than from the expectant treatment of abdominal contusions.

Cases of rupture of the intestines operated on within 24 hours of the receipt of the injury, gave 55 per cent. of recoveries against 25 per cent. in those not operated on. Those operated on after 24 hours (but still in the first days) showed 25 per cent. of cures.

The united results, 33·3 per cent. of cures in cases that were operated on, against 2·5 per cent. in cases that were not operated on, speak still more loudly and unmistakably in favor of operative measures.

According to our experience, and as is laid down in the text book of VON KONIG, the operation, to have the best chance of success, should not be postponed more than 12 hours after the injury, for every additional hour rapidly increases the gravity of the prognosis; especially so, when the teaching, much too widely followed, of waiting for definite symptoms of peritonitis, is adhered to.

Yet experience has shown that the chances of cure are better under operation, even when peritonitis has fully developed, than when no operation is performed.

The peritonitis *per se* does not contra-indicate operative measures, operation is admissible at every stage, only the recuperative power of the patient is not so good.

In our cases, those operated on after 12 hours all died; the only case that recovered was operated on 9 hours after the injury.

Certainly some of the cases were operated on too late, but in the majority of our cases the bad results were not due to the operation being undertaken too late, but to severe and unavoidable complications, as is shown in the histories already related, such as degeneration of the heart, shock, the operation having to be discontinued, etc.

In addition there are however a series of other contingencies—such as overlooking a second perforation, the giving way of a stitch in contused tissue, secondary perforation from necrosis of bruised and contused places in the intestinal wall,

severe hemorrhage etc.,—which according to the experience of the observer may be the cause of disappointing results.

Since in injuries of the abdomen caused by blunt force it is always almost impossible to exclude with any certainty rupture of the intestine, the opinion which we have formed is, that in doubtful cases, that is in the majority of cases which rapidly develop serious symptoms, the proper course is as follows.

Not to waste time on the opium treatment which is almost altogether hopeless, but at the earliest possible moment to open the abdomen by a small incision, and if the presence of a perforation is verified, to enlarge the incision and close the perforation by means of stitches.

While strongly urging early operative measures, it must be clearly understood that we do not recommend operations to be undertaken blindly. But when a careful investigation of the nature of the force, causing the injury, and the immediate or early appearance of complex symptoms in a measure confirms the suspicion that a rupture of the intestine is present, then we have the necessary indications for speedy operation.

A few words concerning the technique of the operation. It goes without saying that the operation should be performed as quickly as possible in cases when shock is passing off, or where there are signs of collapse coming on.

The first thing is a small punctured incision chiefly for diagnostic purposes, this may be made in the middle line, or as we have repeatedly done, over the site of tenderness, it may be done with a local anæsthetic such as cocaine, one per cent. solution. The further laparotomy where necessary, must be done under general anæsthesia.

It is sometimes very difficult to find the perforation which may be situated far back close to the spinal column, though we are certain of its presence from the evacuation of gas, or of serous, purulent, or fecal matter.

It is our custom after a careful examination of the superficial loops of intestine to search the remainder methodically by drawing out a portion, examining it thoroughly and at once replacing it, sometimes it is necessary to take out large portions at once, especially when the convolutions are extensively matted together. The adhesions are often very fragile and must of course be handled carefully, as in some cases they form an important barrier against the further extension of peritonitis, or may protect a bruised and necrotic portion of the intestinal wall from threatening perforation.

Regarding the seat of the rupture, important information is sometimes given by the character of the contents of the gut that have escaped, (particles of food, fecal matter) or by the extent and thickness of the firm purulent exudation in its neighbourhood.

When the perforation is found it is necessary to smooth the bruised and irregular edges, and the prolapsed mucous membrane, so as to close the opening by two rows of LAMBERT'S stitches inserted into sound tissue; it is also necessary to stitch up bruised portions of the intestinal wall, and ruptures of any of the layers, so that should necrosis occur, the necrosed portion may be pushed into the lumen of the gut without causing a perforation communicating with the abdominal cavity.

Should the condition be such that the necessary stitching would cause too great narrowing of the lumen of the gut, then resection of the injured portion is indicated; if however the condition of the patient does not permit of this being done at once, the injured portion should be brought as superficial as possible and the abdominal wound packed around it with sterile or iodoform gauze, so that secondary resection may be undertaken when the patient is able to bear it.

The employment of MURPHY'S or FRANK'S absorptive button will much shorten the operation of primary resection. Under certain circumstances the stitching of the intestinal wound to the abdominal wall (artificial anus) may be recommended.

If an extensive collection of blood be found in the abdominal cavity, its source should be carefully looked for; extensive hæmorrhage is rare in wounds of the intestine, more common in wounds of the mesentery and omentum, and most frequent in wounds of the parenchymatous organs when it is often very difficult to check.

(Wounds of the liver and kidney may be packed or stitched, the spleen extirpated etc.) wounds of the mesentery and omentum should of course be stitched.

We have entirely abstained from washing out the abdominal cavity, as it is usually useless and is even dangerous, we remove the escaped intestinal contents and clean out the cavity with swabs wrung out of salt solution.

Where there is a large collection of intestinal contents in the pelvis, we introduce a gauze tampon, leading to the lower angle of the abdominal incision.

Finally I may recommend the use of salt solution (1000 ccm directly under the skin immediately after the operation, sometimes even before), it makes the patient feel more comfortable, increases the strength of the heart beats and diminishes thirst; we frequently employ it in prolonged operations especially on the abdomen.

SUPPLEMENT.

After sending the foregoing communication to the Editor, I have had the opportunity of operating upon another case of abdominal contusion.

This case differs in important respects from the preceding ones, in it the effect of the injury was to cause a perforation in a loop of intestine lying in a hernia, and in addition, a double perforation in the duodenum at a distance from the hernia.

This case also proved fatal in spite of early operation; the two perforations alluded to were very small, very high up and deeply hidden, so that in spite of evisceration they were not discovered, accordingly the patient, though doing well at first, died on the fourth day after the injury from peritonitis, which even at the time of the operation was well advanced.

VIII W D, 55 years old, on the evening of the 25th May 1898, was admitted to the clinic to which he had come on foot. He said that about one o'clock in the afternoon while eating some food in the street, he had stumbled and fell striking his abdomen against the edge of a kerb stone. He was unable to get up at once and felt a severe pain in the abdomen, he afterwards managed to walk to his house, and in the evening to the clinic.

For many years he had had a right sided hernia, which was easily reduced, and kept in position by a truss, which however the patient had not been wearing for some time; he believed that the hernia was down at the time of the injury.

When he reached his house he tried to reduce the hernia himself, but could not do so on account of the pain it caused. For some time he had suffered from severe chronic bronchitis, and coughed up a large quantity of thick phlegm. The bowels had been relieved a short time before the accident, no flatus had been passed since, urine was passed spontaneously and contained no blood.

On admission at 6 P. M. the patient's face betrayed no sign of severe illness. He complained of pain in the hernia and in the abdomen, his pulse was full, strong, 80 beats; temperature normal.

Even at the first examination it was noticed that the hernia, which was on the right side and about the size of the fist, was very firm and tense and pretty painful. The percussion note was dull. No attempt was made to reduce the hernia which appeared to be strangulated. The abdomen was much distended and absolutely dull on both flanks as far forward as the mid-axillary line, the dulness did not alter with careful changes of position. The front of the abdomen was tympanitic all over, the liver dulness was normal. Tenderness was marked over the whole front abdomen, but especially so between the umbilicus and ensiform cartilage.

Immediately after admission an operation was proposed under the idea that the fall had caused strangulation of the hernia, in spite of much persuasion however the patient stoutly refused.

Towards 10 o'clock in the evening the temperature rose to 101.4°F. The pulse was weaker, 100 beats, but was still relatively good. The painfulness and tenderness of the hernia had increased, the abdomen was more distended, there was more pain above the navel, the dulness in the flanks had increased forwards and almost reached the mammary line on both sides. The liver dulness was normal. No flatus had been passed. The patient who had coughed up large quantities of phlegm had vomited and had a drawn expression.

The obvious diagnosis now was, that in addition to a strangulated hernia, there was a rupture of the incarcerated portion of the gut with a probability of some further injury to the intestines; and now eleven hours after the accident the patient gave his consent and late as it was the operation was at once proceeded with.

In the first place an incision was made in the usual manner over the most prominent part of the hernia; the sac was much thickened and infiltrated with sanguineous serum. On opening it a large quantity of fluid mixed with fecal matter escaped; the knuckle of intestine was covered with dirty matter and on its convexity there was a circular perforation with irregular, bulged out edges and mucous membrane much prolapsed.

The opening into the abdomen was narrow and firm, so the surrounding ring was notched in several places, which allowed a small quantity of muddy fluid to escape from the abdominal cavity.

The wound was plugged provisionally and an immediate exploratory laparotomy begun in the middle line. On opening the peritoneum, there rushed out a large quantity of muddy brown fluid, without any fecal odour. The parts of the intestines that were visible were covered with a fibro-purulent exudation. The incision was enlarged, beginning at the symphysis pubis and extending above the navel.

The amount of fluid that was evacuated measured 1½ litres. The intestines and their serous covering were intensely red all over, and covered with a copious fibro-purulent exudation, in many places they were so intimately bound together that it was impossible to break down the adhesions without injury to the serous coat. Between some of the intestinal loops there was thick pus.

Taking the greatest possible care of the adhesions, which were not so extensive in the superficial as in the deeper parts, the whole of the intestine was searched and almost completely eviscerated without any perforation being found. That a perforation existed I was convinced from the quantity of muddy exudation, yet I hesitated to break down adhesions which quite possibly might be the means of closing a small opening. After cleaning out the abdominal cavity as carefully as possible and replacing the intestines the laparotomy wound was stitched up.

THE INDIAN MEDICAL ASSOCIATION.

ESTABLISHED AND REGISTERED 1894.

OFFICE AND LIBRARY :
50, Park Street, Calcutta.

TERMS OF MEMBERSHIP

Every man or woman, who being duly and legally qualified to practice medicine, by virtue of holding a degree or diploma or qualification in medicine, whether British, Indian, Colonial, European or American, whether from State Institutions or Independent Medical Schools, and every person holding a Government Certificate entitling such person to practice Medicine in any official or private capacity, shall be eligible for election to Membership in the Association.

Every person desirous of becoming a member, shall send an application in the form given below, to the Secretary of the Association, and the Council shall consider and dispose of same at their next meeting. On any person being elected a member, an intimation to the effect shall be notified in the Journal of the Association, and on payment of the subscription, a certificate of membership shall be issued.

Application for Membership.

I, _____, residing at _____, am desirous of being elected a Member of the Indian Medical Association; and I agree to pay the subscription, and to conform to the Rules and Regulations now existing, or which hereafter may be made by virtue of the same.

Name..... Address.....
Professional title Date.....

Every Member shall pay a subscription of five rupees per annum which shall entitle him to all the privileges of membership. The subscription shall be considered due in advance on the 1st January in each year, and should be forwarded to the Treasurer.

The *Indian Medical Record* is the Journal of the Association, and is the medium of communication between Members of the Association. In it shall be inserted the Transactions and Proceedings, and all notices of meetings of the Association, and any other business which the Council deem necessary.

The Reading Room and Library of the Association are open to all members of the medical profession from 10 A. M. to 5 P. M. daily (except Sunday.)

Members who have paid their subscription to the Association, may obtain their membership certificates and copies of the First, Second and Third Annual Reports of the Association by applying to the Secretary. Name and address to be plainly written.

Officers and Council :

President :—Lal Madhab Mukerji, Rai Bahadur, L.M.S., F.C.U., Principal, Calcutta Medical School.

Vice-Presidents :—(1) E. W. Chambers, L.M.S., L.S.A., Lond.

(2) H. H. Sir Bhagwat Sinha, G.C.I.E., M.D., C.M., F.R.C.P. Edin., LL.D., D.C.L. Edin., Thakore Sahab of Gondal, Kathiawar.

Members of Council :—Representing Bengal and resident in Calcutta (4 members).

1. H. W. Jones, M.D., M.R.C.S., Eng.

2. J. G. Anderson, G.M.C.B.

3. K. G. Sinker, M.B., L.R.C.P., Edin.

4. Nihal Das Ghose, L.M.S.

Representing—

5. *Bombay*.—Alfred McCabe-Dallies, L.M. Dub., L.R.C.P. Ire.

6. *Madras*.—O. G. R. Naylor, M.R.C.S., L.R.C.P., Lond.

7. *Central Provinces*.—Mirza Karim Khan, M.B., C.M., Edin.

8. *Punjab*.—Professor C. O. Galeb, M.B., M.S.

9. *N.W.P. and Oudh*.—John Morton, M.D., L.R.C.P. & S. Edin.

10. *Burma*.—N. N. Parakh, L.S.A. Lond., L.F.P.S. Glas.

11. *Independent Native States*.—A. Mitra, Rai Bahadur, L.R.C.P. and S. Edin.

12. *Assam and Dacca*.—Wm. Brown, M.B., C.M. Glas.

13. *Representative of Military Assistant Surgeons' Service*.—Major James Forsyth, S.A.S., H. E. The Viceroy's Staff.

14. *Representative of Civil Assistant Surgeons' Service*.—Hari Datt Pant, L.M.S., Assistant Civil Surgeon, Gonda, Oudh.

15. *Representative of Hospital Assistants' Service*.—J. M. Philip, C.M.S., Government Ophthalmic Hospital, Madras.

Treasurer.—Major H. C. Hodgkins, S.A.S., Medical College, Calcutta.

Secretary.—James R. Wallace, M.D., F.R.C.S., Editor, *Indian Medical Record*.

Solicitors.—Messrs. Dignam and Co., Attorneys-at-Law, High Court, Calcutta.

Bankers.—Messrs. Grindlay and Co., Calcutta.

RULES AND REGULATIONS

OF THE

INDIAN MEDICAL ASSOCIATION PROVIDENT FUND.

I. The Fund shall be called the Indian Medical Association Provident Fund.

II. The Fund shall be registered under Act XXI of 1900, and the Registered Office shall be situated in Calcutta.

III. The object of the Fund is to give members of the medical community in India and Burma an opportunity of making provision for their families on the mutual benefit system.

IV. Any medical man or woman, may become a member of the Fund.

V. The Fund shall consist of two classes of subscribers, namely, (a) those who are members of the Association called Associate members, and (b) non-members of the Association called "non-associates." The subscription in each class shall be as follows:—

(a). Every non-associate shall, on joining, pay an entrance fee of Rs. 10, which shall be credited to the capital of the Fund.

(b). An annual subscription of Rs. 6 shall be payable by every non-associate member which shall go to meet the working expenses of the Fund.

(c). Members of the Association will pay no entrance fee and no annual subscription. They will pay only their fee of Rs. 6 as members of the Association and the "calls" of rule (d).

(d). On the decease of any member, a call of Rs. 1 per head will be made on all the other members of the Fund of both classes.

(e). To meet such calls, members of each class shall place in deposit in the Fund, a sum of not less than Rs. 3 at a time, to be renewed before the last rupee on hand has been paid on his account.

(f). Notice of the payment of a call shall be given by a post-card, and through the *Indian Medical Record*, which shall contain a statement of the sum paid on account of the member to whom it is addressed, and of the balance to his credit held in deposit in the Fund, and this shall be deemed a sufficient receipt for the payment of the call.

VI. The nominee or nominees of each subscriber shall, at his death, receive a bonus calculated at the rate of Rs. 1 per head for each and every registered subscriber of the Fund, and who has a deposit in the Fund to meet the call.

VII. The claims of nominees in each class shall be paid as follows.—One-half on submission of certificate of death and surrender of entrance certificate (Rule X), and the remaining half, in accordance with the terms of Rule VII, after the claim is admitted by the Directors in meeting.

VIII. Applications for admission to the Fund must be made on a prescribed form which shall contain clearly written:—

(a). The full name, age, and address of the applicant.

(b). The class he wishes to join.

(c). An engagement on his part to submit to and abide by the rules of the Fund.

(d). The name, age, and address of the nominee or nominees for whose benefit he joins the Fund.

(e). And in the case of nominees who are minors the names and addresses of two or more guardians other than the subscriber, appointed in each case, to whom the bonus will be paid.

Every application must be accompanied by the entrance fee specified in Rule V (a), or by a postal money order or cash as subscription and "call" deposits due from associate members.

IX. A certificate of membership in the form prescribed shall be issued to each subscriber by the Secretary and Treasurer as soon as his name has been registered. This certificate may be renewed in favour of a fresh nominee on payment of Rs. 8 and surrender of original certificate. On a like payment being made, a duplicate certificate may be granted when the original is lost or destroyed.

X. Claims for payment must be submitted on a prescribed form containing a certificate of the death of the

according to priority of application, on a formal identification of the nominee, who shall be required to surrender the entrance certificate granted under the preceding rule.

XI. Every subscriber shall keep the Secretary and Treasurer of the Fund duly informed of any change in his address. If he fails to do so, he shall have no cause of complaint against the Fund for any disadvantage arising from such neglect.

XII. Any subscriber who fails to renew his deposit for payment of calls before it has been exhausted, and so cannot meet a call under Rule V (c) nor the subscription specified in Rule V (b or c) within the year for which it is due, shall, after reasonable enquiry, be adjudged a defaulter, and shall forfeit all claims upon the Fund. Nothing in this Rule, however, shall prevent a subscriber, whose name may have been struck off as a defaulter from joining the Fund as a fresh member on payment of all arrears.

XIII. The Fund shall be managed by a President and three Directors resident in Calcutta, nominated by the Council of the Indian Medical Association from amongst their own members.

XIV.—An Auditor, who shall be a Councillor other than a Director, shall be elected annually by the Council, the accounts being submitted to such Auditor quarterly for audit.

XV. The half-yearly Report of the Fund shall be published in the *Indian Medical Record*, after it has been placed by the Directors before the Council of the Indian Medical Association.

XVI.—The Annual Report of the Fund shall be placed before the annual meeting of the Indian Medical Association.

XVII.—Any member of the Fund having a grievance against the Directors or Treasurer of the Fund may appeal to the Council of the Association for a consideration of his case.

XVIII.—The Directors shall meet once a quarter for the transaction of business, and shall have power to make, vary, or repeal bye-laws for the regulation of the affairs of the Fund, subject to approval at the next annual general meeting of the Association.

XIX.—All receipts, except sums credited to Working Expenses Account, shall be paid into the Bank of Bengal. When the sum accumulated in the Bank to the credit of Capital Account, in excess of the amount required to meet a call, admits of the purchase of Government Securities, an investment shall be made, and the interest obtained therefrom credited to Working Expenses Account.

XX.—When any question arises which, in the opinion of the Directors, should be referred to the whole body of subscribers, or which involves the repeal or alteration of or addition to, any of the rules of the Fund, the votes of subscribers shall be taken thereon, and the question so referred shall be decided by the majority of the votes received within one month from the issue of the circular.

FORM OF APPLICATION FOR ADMISSION.

TO THE SECRETARY AND TREASURER,

Indian Medical Association Provident Fund, Calcutta.

DEAR SIR,

(Station) _____ 189

I,

hereby apply to be admitted as (1) ^{associate} ~~non-associate~~ member of the Indian Medical Association Provident Fund, Calcutta, on behalf of my (*) _____

now _____ years of age, residing in _____ and I bind myself to submit to, and abide by, the Rules and Bye-laws of the said Fund.

I also agree that all claims on the above Fund shall be forfeited by my nominee, should I neglect to pay my dues.

I forward herewith Rs. _____

Yours faithfully,

Usual Signature and Address _____

(1) Write out one word or the other to indicate which class you join.

(2) Here state relationship. No minor will be accepted as a nominee unless two or more guardians appointed, to whom the bonus secured will be paid, the name and address of each guardian being clearly written on the back of this form.

(PRINTED BY THE SECRETARY)

From the herniotomy wound an iodiform gauze tampon was inserted into the abdominal cavity, the loop of intestine that was ruptured in the hernia was left outside, and was dressed with iodiform gauze and moist salt solution compresses.

For the first two days after the operation the result was satisfactory. The pulse and temperature were normal, there was no vomiting, large quantities of fecal matter were evacuated from the opening in the gut. The trouble caused by the bronchitis was diminished by small doses of morphia.

On the 3rd day the temperature rose to 101.4°F, the pulse was weaker, the abdomen was more distended and more painful. In the night between the 3rd and 4th day sudden collapse set in and the patient died on the morning of the 4th day.

Post-Mortem—; diffuse peritonitis, the large opening in the intestinal loop which lay outside was about 50 cm. from the ileo caecal valve; for a distance of about 30 cm. from the perforation, the mucous membrane of the intestine was dotted with small extravasations of blood; the intestinal wall was much thickened and the intestines in several places tightly bound together. After a prolonged search two small perforations were found lying close together in the duodenum about 30 cm. from the pylorus, the edges were irregular and the mucous membrane prolapsed in their neighbourhood, the intestines were less close bound together than in the rest of the abdomen. In the mucous membrane about the perforations there were several well marked extravasations of blood. In the abdomen there was only a very small quantity of muddy fluid. In addition were found signs of bronchitis, fatty liver and degeneration of the kidneys.

The perforation in the portion of the intestine lying in the hernial sac was evidently caused by bursting, owing to a sudden increase of pressure within the intestine. The escape of the intestinal contents was prevented by the narrowness of the opening into the abdominal cavity which was probably even more contracted at the moment of the accident. As a consequence, the force of the increased pressure was exerted upon the convexity of the loop where it caused a rupture, this explanation is born out by the bulged out edges and much prolapsed mucous membrane.

As in our earlier cases, it is much more difficult to explain the occurrence of the two small perforations in the duodenum; they may have been caused in the same way as the perforation in the hernia,—by an increase of internal pressure,—possibly also by direct crushing against the neighbouring special column, as in some of our other cases (case IV. for instance). It may be that they were secondary perforations following upon severe contusion of the intestinal wall, as careful search upon dissection failed to discover them at the time of operation.

We are however inclined to think that they were the direct results of the injury on account of the large amount of muddy, non-faecal, fluid removed at the operation: this could hardly have been due to peritonitis alone, considering the relatively short time of eleven hours which had supervened between the injury and the operation.

The situation of the small perforations was very much concealed and was only found with difficulty by drawing over the duodenum, considering the small degree of motility of this portion of the gut and the presence of adhesions it would have been impossible to have exposed them clearly and sewed them up at the operation.

Whether the diffuse peritonitis which was already present at the time of operation could have healed these perforations is impossible to say.

Nevertheless this observation also shows what a relatively small amount of blunt force can produce injuries of the severest kind, that such injuries are not negated by the absence of severe symptoms at the onset, and the necessity of performing an exploratory laparotomy at the earliest possible opportunity to obtain the most accurate information concerning the results of the injury.

Current Medical Literature.

MEDICINE.

Early Treatment of Syphilis.

NEUMANN holds that no remedy can be depended upon to ward off the onset of constitutional symptoms in syphilis; the most that results is their temporary postponement. He admits, however, that exceptionally abortive treatment appears to be successful. Mercury and iodine are specific anti-syphilitic remedies which do not destroy the cause of syphilis, though they control its products. No other remedy is yet known which acts directly on the cause of syphilis, whatever that may be, and of this many proofs can be adduced. Thus the abortive treatment would, if these remedies acted on the cause of syphilis, utterly destroy it before it would take possession of the whole organism. But of 100 cases thus treated in NEUMANN's clinic, none remained free from secondary symptoms. Again saturation of the organism with mercury or iodine does not prevent relapses, which have occurred up to fifty-five years after infection. Late syphilitic manifestations appear most frequently on the very sites of the early lesions, which would be impossible if the cause of the disease had been destroyed. *Per contra* mercury and iodine are often ineffectual in well-marked syphilis. By whatever remedies and in whatever manner treated from 6 to 22 per cent. of syphilitics remain uncured, that is, develop tertiary symptoms. From these considerations NEUMANN concludes that the symptomatic treatment of syphilis is the sole rational one, and that it acts by establishing a temporary or permanent immunity to the ever-present cause of the disease. The "chronic intermittent" treatment of Fournier referred to above is not to be recommended, as the results obtained by it are no better than by the symptomatic method.—*Brit. Med. Jour.*

Heart Complications in Diphtheria.

DR. CLYDE M. HILSBARD, of the Boston City Hospital, has published the results of a systematic study of the heart complications in a large number of cases of diphtheria treated in that hospital. The results of the *post-mortem* examinations in the seventy-two fatal cases which occurred are given in the report, and these results are largely drawn upon in formulating the following conclusions reached by the author:

(1) A rapid pulse-rate in diphtheria is to be dreaded. Death usually results when it exceeds 150.

(2) A slow pulse—60 in young children—is a sign often of serious heart trouble.

(3) Irregularities in the pulse occur in about ten per cent. of the diphtheria cases and are generally significant of cardiac complications.

(4) A systolic murmur at the apex is heard in about one case in ten, and its prognostic value depends upon the nature of the cause.

(5) A bruit de galop in diphtheria is a most fatal sign.

(6) After four weeks, with no heart symptoms in diphtheria there is little probability of subsequent cardiac trouble in the convalescence.

(7) All diphtheria patients who have tachycardia, bradycardia, irregular or weak pulse, a systolic murmur at the apex, vomiting or any paralysis—especially palatal—should be kept quiet in bed.

(8) The most important element in the treatment consists in absolute rest in bed.

(9) The vagus nerve in the fatal cases always had some evidence of degenerative changes. The weight of the heart was increased.

(10) The cause of death is usually from cardiac thrombi, dilatation or paralysis, produced most probably by the toxin of the diphtheria bacillus.—*Gaillard's Med. Jour.*

Treatment of Diarrhoea in Children by Sterilized Water.

MONGOUR says that the intestines of infants suffering from gastro-enteritis contain in great numbers, and in a higher degree of virulence, those bacteria which produce abnormal fermentations in the articles of food which they ingest. There are therefore two indications for treatment; first, to free the intestines as quickly as possible from the products of fermentation, and second, either to frequently change the contents, in which the bacteria develop, or else to keep these fluids in an aseptic condition. The first indication is secured by laxatives, but these cannot be many times repeated in the case of a weakened child. Asepsis of the intestine cannot with certainty be obtained. It is easy, however, to frequently renew the nourishment, although such children suffer more from lack of water than from lack of food. Moreover, water is one of the poorest media for the development of bacteria which it is safe to introduce into the stomach. The clinical results are in accord with this theory, and if a child is given from ten to twelve ounces of sterilized water daily, vomiting will cease at once, diarrhoea will soon disappear, and the temperature will fall so, that in a relatively short time milk can again be given. Absolutely no medicine will be required. MONGOUR has obtained most brilliant results from this simple treatment.—*Med. News.*

Sign of Grave Facial Paralysis.

DRS. BORDIER and FRENKEL have noted a new phenomenon in peripheral facial paralysis, which has considerable prognostic value. This is the rotation of the ocular globe from above downward during the act of closing the eyelids. BONNIER says he has encountered this sign in all cases that he has observed. FRENKEL and BORDIER explain it as an actual nervous discharge, voluntary excitation, having no action on the facial, discharges itself in another way. Dr. BONNIER thinks that it is a simple derangement in moticity. CAMPOS thinks that it is a physiological phenomenon becoming more manifest by the fact of a more considerable nervous impulse, and that the phenomenon is more manifest according as the impulse is more intense—that is to say, as the paralysis is more marked.—*N.Y. Med. Rec.*

Influence of Alcoholism in the Father upon the vitality of the Children.

THE mother, a robust, healthy woman, was married at 17 to a chronic alcoholic. During her nine years of married life she had five puny and ill-nourished children. Four of them died in the first ten days after birth from malnutrition, the remaining one by careful nursing attained the age of 1 years before succumbing. The mother then became divorced from her husband and remarried, this man, however, being perfectly healthy and strong; to whom she had 2 children. The eldest one, now 4 years of age, is the picture of health; the youngest, 14 days old, is just as stout and healthy. This marked contrast between the two sets of children is, in the absence of syphilis, very significant of the ill-effects of paternal alcoholism.—*Phil. Polytechnic.*

SURGERY.

Colles' Law.

HOCHINGER discusses COLLES' law as it now stands, also the questions connected with it. His conclusions are as follows: (1) Healthy women who have been impregnated by syphilitic men can give birth to syphilitic children, but themselves remain free from syphilis all their lives. (2) Women who are pregnant with the fetus of a syphilitic father, but free from contact infection from him, acquire through such a pregnancy a certain but very variable degree of immunity against syphilis, which has been the foundation of the so-called COLLES' law. (3) COLLES' immunity of the mother is the result of immunising substances derived from the spermatically infected fetus, and is not absolute. (4) The exceptions to Colles' law concern women who, for reasons not always easy to discern, have only absorbed an insufficient quantity of the immunising substance during pregnancy, or in whom the requisite tissue activity for the establishment of immunity is absent. (5) A retro-infection of the mother from a spermatically infected fetus, the so-called *choc ex retour*, or "syphilis by conception," is clinically not proved, and not provable, although theoretically not difficult to establish. (6) Finger's hypothesis of the toxic nature of tertiary syphilis, and of the crypto-genetic tertiary infection of the mother, is incompatible with Colles' immunity, and is at variance with the pathological anatomy and clinical experience of early congenital syphilis. (7) Hereditarily syphilitic children infected by the father should not be suckled by the mother if it is her first child, and she is free from syphilis. If the mother has several spermatically infected children and is still free from syphilis she may safely suckle a child.—*Pav. Med. Jour.*

Adhesions of liver and gall bladder in association in the tumours of the female generative organs.

FREUND has made a careful study of the adhesions that may be found between tumors of the female genital organs and pelvic and abdominal viscera, especially the liver and the gall-bladder. These adhesions may at times be so dense as almost to make the operation of extirpation of a tumor impossible. They are found in cases not only of ovarian cysts but also of uterine myomata. A case is reported of marked adhesions in a patient, 58 years of age, in which tapping had been performed 20 times, dark fluid having been removed at each puncture. The patient presented signs of ascites, jaundice, cachexia, and edema, all of which seemed to indicate some form of malignant degeneration. Ovariectomy was performed under chloroform-anesthesia, the tumor proving to be an enormous polycyst of the ovary. Owing to the frequent tapplings, adhesions were found everywhere from the liver and the diaphragm down, necessitating in addition the performance of cholecystectomy. The time occupied by the operation was three quarters of an hour. The patient made an excellent recovery. A second case occurred in a woman, 65 years of age, who presented a colossal multinodular fibromyoma of the uterus adherent to the liver, stomach, mesentery and peritoneum. The hemorrhage from the liver at the time of separation was terrific. The patient, however, made a good recovery.—*Phil Med. Jour.*

Fractures.

DR. W. L. ESTES, in the *Internat. Jour. of Surgery*, says:—

I. Unless a fragment is threatening to break through the skin the fracture should never be reduced except by the physician, and then only when apparatus is at hand to keep the parts in permanent apposition.

2. Men carrying an injured person should not keep step as the jar to the wounded part is much greater.

3. Strychnia for shock, morphia for pain, but no alcohol.

4. Always give anesthetics for reduction of a simple fracture. It is better and easier to reduce and set compound fractures without anesthesia.

5. It is very rarely necessary to make a patient go through the double agony of temporary and permanent setting of the broken bones.

6. In simple fracture gentle rubbing of the ends will assist in getting rid of shreds of tissue which invariably are caught there.

7. Nowadays a surgeon will rarely be satisfied that a bone is properly set, until verified by the X-Rays.

8. Plastic splints, preferably plaster-of-paris, are surely the best apparatus when they can be applied.

9. Ambulant treatment is coming more into vogue. No simple fractures require constant confinement to bed, except of the innominate and upper third of the femur.

10. It is not necessary and is sometimes very harmful to wait for swelling to disappear, before putting on a permanent dressing.

11. A well-applied splint with good apposition of fragments should not be removed too early. It is not necessary to apply massage early in ordinary cases.

12. Proper time for massage is two or three weeks after fracture of upper extremities and four or five weeks for lower extremities—if the bones are slow to unite firmly.—

Simple Method of Curing an Ingrowing Nail.

TARDIF says that he has been able to cure all cases of ingrowing nail, without recourse to the knife. He proceeds as follows: With a flat probe, or a match, he slips a bit of cotton between the edge of the nail and the inflamed flesh. Another strip of cotton is put along the outer margin of the ulcerated area, and the space between these two strips of cotton, and which is occupied by the ulcer, is thickly powdered with nitrate of lead. The whole is covered with cotton, and the toe is bandaged. The dressings are repeated the following day, and every day until the incarcerated edge of the nail is plainly visible. Usually four or five dressings suffice. Then with patience the edge of the nail is lifted away from the flesh and a bit of cotton is introduced under it, to keep it up. As it grows it will gradually take its proper position above the flesh, this having in the meantime shrunk and shriveled by reason of the applications of lead nitrate. The lead is to be discontinued as soon as it appears that the exuberance of the fleshy bed of the nail has been overcome. The difficulty seldom recurs. If this does happen it is necessary to repeat the treatment from the beginning.—*Méd. News.*

Intestinal Invagination in Infants.

CORDUA reports twelve cases; two were cured by energetic massage, enemas and the insufflation of air. Five recovered out of seven operated on during the first two days; two died from shock. Three were operated after the second day, all dying from gangrene and consecutive peritonitis. From a review of 184 cases in literature, he concludes that in operating great care must be practiced to avoid hernia later. In a case of gangrene there should be resection, enterotomy, entero-anastomosis, but infants under a year can not stand such a serious operation and those over a year but little better.—*Gaz. de Osp. ed. Clin.*

OBSTETRICS AND GYNÆCOLOGY.

Prolonged Retention of Placenta in Recurrent Abortions.

On July 10th I was summoned to a woman, who had a severe uterine hæmorrhage following an incomplete abortion three weeks previously. She was in a profound state of collapse, rambling at intervals, with extremely feeble pulse and sighing respiration. There was visible proof that she had had a great loss, and on examination large blood clots were found blocking the vagina; the os was contracted, and the cervix bore evidence of long-standing lacerations. Ergot was given in full doses, and after a time the bleeding ceased.

She went to stay with friends on June 13th; while there she had a fright, and aborted on June 18th, being then in the fourth month of gestation. She was assured that everything had come away, but being sceptical as to the expulsion of the placenta, she resolved, after lying up for a few days, to return to her home here on June 21st. I saw her soon after her arrival and enjoined absolute rest in the recumbent position. For the following three weeks she had neither loss nor fetid discharge, and latterly was feeling quite well.

The placenta was expelled by natural pains on the morning of July 11th; the membranes were degenerated, but the placenta was fresh and well formed, and no odour of decomposition could be detected.

This is the eighth abortion, and in all—with one exception—the placenta has been retained for periods varying from two to six weeks. She never goes beyond the fifth month of pregnancy, and usually makes a rapid recovery. She is strong and well-built, aged 35, and there is no history of syphilis. Her first three children were born at full time, and in each case forceps were used. At the third parturition extensive laceration took place, and ever since she has suffered from a vesico-vaginal fistula which has baffled the efforts of several hospital surgeons to alleviate; from this period also dates the commencement of her abortions.

Other important features worth noting in this case are (1) the long distance travelled soon after the fetus was expelled, the railway journey alone occupying nine hours; (2) the flaccidity of the mammary glands continuing long after the expulsion of fetus, the milk appearing on the third day after placental expulsion, when the quantity became abundant—this condition has existed in all the eight miscarriages. I can personally verify its truth, having attended her in the last four abortions; (3) absence of septicæmia. B. WIGGINS L.R.C.P., L.R.C.S. Edin.—*Brit. Med. Jour.*

Fetus in Broad Ligament: (?) Criminal Abortion.

M. HIVER, of Paris, related at the April meeting of the *Société Obstétricale et Gynécologique de Paris* a case of perforation of the pregnant uterus, a three-months' fetus being forced into the parametrium between the layers of the left broad ligament. This case is of great importance in respect to evidence relating to suspected criminal abortion. A multiparous woman, aged 41, was admitted dying into Professor LE DENTU's wards in the Hospital Necker one day last March; she died within half an hour of admission. The period had been absent for three months and a half. For three days the woman had complained of violent hypogastric pains and on the night before admission there were symptoms of internal hæmorrhage. A practitioner detected retro-uter-

ine hæmatocoele involving the left fornix. At the necropsy the coils of small intestine in the pelvis were found covered with the exudation familiar in the lowest type of peritonitis. There was no blood in the peritoneal cavity, but the layers of the left broad ligament were separated by a large hæmatocoele, which extended into the vesico-uterine pouch forwards and posteriorly passed behind the peritoneum into the lumbar region. The fundus uteri reached above the pubes; the tubes and ovaries were free from any disease or abnormality. On laying open the distended left broad ligament, a three month foetus was found lying in a mass of clot and blood. The pouch in the broad ligaments formed by the hemorrhage was now to communicate with the uterine cavity by a circular perforation as large as a five-franc piece, situated in the left and anterior aspect of the supra-vaginal part of the cervix. The placenta was attached to the foetus, and lay in the abnormal pouch. Its original seat was the anterior aspect of the inner surface of the uterus. There was no disease of the walls of the uterus, and no history of an external injury. Spontaneous rupture of the uterus at the third months is unknown and out of the question in this case where the walls were normal. The perforation was evidently due to an internal injury, most probably caused by a rigid stem. When once produced, it is easy to understand that the uterine contractions set up by the injury managed to force the foetus and its placenta into the parametrium. No doubt septic infection caused inflammation of the peritoneum, itself unwounded. Had the patient recovered for awhile, and died later, after the healing of the uterine wound, the condition might have been taken for a rare variety of extra-uterine pregnancy.—*Brit. Med. Jour.*

Painful menstruation—causes and treatment.

IN reviewing the subject, LAWRENCE presents the following conclusions:

1. Painful menstruation is not a disease, but merely a symptom found in various pelvic diseases.
2. Those classifications which place it as a disease are misleading and should be discarded.
3. The physiology of menstruation, a thorough knowledge of pelvic pathology, and a broad, careful habit of study and thorough case-taking, are necessary in order that menstrual pain be rightly construed.
4. Many of the cases, due to the uterus, tubes, or ovaries, may be cured in the early states by simple means, whereas neglect places them in a position demanding serious operative treatment.
5. Painful menstruation in a sterile patient is strong evidence that there is tubal inflammation with occlusion of tubes.
6. Operative procedures should be reserved for those cases in which there is a positive pathological indication; neurotic and anemic cases being treated by other and more appropriate measures.
7. As a symptom menstrual pain is often of such grave import that it should always receive the most painstaking study. If this be the rule, many a case will be cured without operation.—*Canad. Prac.*

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

Relation of the Thyroid Gland to the Female Genitalia.

By Dr. G. N. DE VOGT. The view that the thyroid gland exerts a specific action upon the genitalia is not new. As early as 1838 WUNDERLICH stated that this organ was of great significance in the sexual function. But, in man at least, this is certainly not true, as later experiments, particularly those of Gley, have shown. Some time in the '80s, H. FREUND sought to determine this close relation between the thyroid and the female genitalia, basing his opinion especially upon clinical experience. The majority of cases of struma are found at the time of puberty and of senile involution of the genital apparatus. Furthermore, Basedow's disease occurs more often in women than in men. It is also true that experimental thyroidectomy is followed by alterations in the ovaries, which have been accurately described by HOFMEISSER. But these arguments contain nothing positive? for, because experimental thyroidectomy not only causes alterations in the ovaries, but also in the whole organism, no one will observe anything therein which points to an intimate relation between the thyroid gland and the female genitalia.

If we further consider that great alterations occur in the organism during the periods of puberty and of senile involution, and that the appearance and cessation of menstruation is only a physiological symptom of these alterations, cannot the occurrence of struma during these periods be a pathological symptom of these alterations? And would not this better explain the occurrence of struma than the view that an intimate union exists between struma and alterations in the female genital apparatus? For even in men we find during these years of life the greatest number of cases of struma.

How the frequent occurrence of Basedow's disease in women can be an argument in favor of FREUND's view, is a problem which the author confesses his inability to solve; for true as it may be that Basedow's disease is relatively rare in men, it is certainly not a primary affection of the thyroid gland. Furthermore, there are a number of cases of Basedow's disease in which no struma whatever is found.

In reference to FREUND's theory, the author reports the case of a fifteen-year-old girl with struma and a dermoid cyst of the ovary, upon whom an operation for removal of the tumor had no effect upon the struma. The girl was at the period of puberty, and the appearance of the menses and the first observation of the struma were almost synchronous.

What an important support, says the author, could this case give to FREUND's hypothesis if the struma had disappeared after removal of the ovarian tumor—for, he says, *cessante causa cessabit effectus*—and in the light of this hypothesis the tumor of the ovary would then be the result of the increased ovarian irritation and have disappeared after the ovariectomy. But it was not thus to be! In the author's case the struma remained unaltered, and of the same size.

In conclusion the author states that the opinion expressed by him some time ago in his inaugural dissertation, to the effect that as yet there is no positive proof of a specific function of the thyroid gland in its relation to the female genital apparatus, is strengthened by the observation of the case reported.

Trichinosis.

T. R. Brown gives an account of investigation made by him on trichinosis, with special reference to the increase of the eosinophilic cells in blood and muscle, the origin of these cells, and their diagnostic importance. He claims to have demonstrated: (1) In a case of acute trichinosis an extensive leucocytosis with great absolute and relative increase in the number of eosinophilic cells in the blood, associated with a coincident decrease in the quantity of neutrophilic elements. (2) From the examination of the specimens of muscle removed during life, besides the peculiar degenerations of the muscle, a longitudinal splitting of some of the fibres, a remarkable transverse splitting of others, a great proliferation of nuclei, about many of which vacuoles are seen, and large numbers of polymorphonuclear eosinophilic cells, which were especially prevalent in the more degenerated areas. (3) In a second case after death, besides similar changes in the muscle, large numbers of eosinophiles throughout the infested portion. (4) In two other cases during life a great increase of the eosinophilic cells in the blood, with a coincident increase of the polymorphonuclear neutrophils, associated with leucocytosis, though of less extent than in the first case. (5) In pieces of muscle removed in these last two cases changes in most respects similar to those cited in the first case, but of less degree. (6) The similar character of the nuclei of the eosinophiles and the neutrophils both in the blood and in the muscle, and the presence in the first case of certain cells which might be regarded as forms transitional between neutrophils and eosinophiles, suggesting the possibility that the increase in the latter elements may in these instances take place in the muscle by direct transition from the neutrophils. From these observations BROWN thinks it fair to conclude: (1) That there is a marked decrease in the percentage of eosinophilic cells in the blood in trichinosis. (2) That this increase may be used as a diagnostic sign in this disease. (3) That this disease in its sporadic form is more common than has hitherto been supposed, as shown by the discovery of the three cases above described, within a comparatively short period, at the Johns Hopkins Hospital. (4) That a systematic examination of the blood should be undertaken in cases with indefinite intestinal, muscular, or articular symptoms, in the hope that in some at least of the hitherto doubtful cases a diagnosis may be reached.—*Brit. Med. Jour.*

On Infection with a Para-Colon Bacillus, with all the Clinical Features of Typhoid Fever.

THE name para colon is given to an organism between the typhoid bacillus and the colon, as its properties are so closely allied to both. The patient developed an abscess in the neck about the oesophagus, showing at the same time constitutional symptoms. From the pus an organism was obtained in pure culture, actively motile, decolorized by Gram; it did not liquefy gelatine; clouded bouillon without a film, and a few gas bubbles in glucose agar-agar; grew on potatoes as a yellowish-green film. The two most essential distinguishing points from the colon family were that it produced no indol and did not ferment lactose, while its fermentation of glucose and its growth on a scraped typhoid culture distinguishes it from the typhoid. It had a specific agglutinative reaction with the serum of the patient, which gave no reaction as the typhoid bacilli.

Clinically, rose spots were present; the spleen was palpable; the urine gave the diazo reaction; there was no diarrhoea. Some cases of so-called typhoid fever not responding to the usual reaction with typhoid bacilli may be cases of a para-colon infection.—Dr. GWYN, *Prac. Med. Jour.*

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Progress in Public Hygiene.

Conveyance of infectious diseases by means of the air.—Dr. E. GERMANO reports the results of a series of experiments in continuance of those already reported. The later series relate to diphtheria, erysipelas and pneumonia. He reports the following conclusions in regard to the spread of diphtheria: (1) The diphtheria bacillus can resist drying for a long time, both in the membrane, in the tissues and when present in dust. (2) Increased rapidity in drying, even by means of sulphuric acid, does not effect the resisting power of the bacilli either in the tissues or in the dust. (3) The bacillus survives better the more it is surrounded by dust, probably on account of its greater protection from oxidation. (4) When dried completely, the bacillus retains its virulence until it dies. (5) the air can carry diphtheria while living, by means of dust. With reference to streptococci, he says: (1) The power of surviving the drying process depends largely on the mode in which this is carried out, and the material with which it is mixed. (2) At any rate, its power of resistance is great and can continue for months. (3) The rapidity of drying has no effect on the vitality of the streptococci. (4) The resisting power increases with the amount of material in which it is implanted, and which protects it from the air. With reference to the streptococcus pneumoniae, to which he attributes pneumonia and sometimes meningitis, pleurisy and acute nephritis he concludes: (1) The diplococcus is a micro-organism which can resist drying for a long time. (2) It survives better when dried than when moist. (3) As it can under some conditions exist in a dry condition for a long time, but not to the same extent as the *Streptococcus erysipellatus*, the possibility of its conveyance through the air is established.—S. W. ABBOTT, *Boston Medical and Surgical Journal*.

Four Arguments against Noise.

THE *Philadelphia Medical Journal* for July 16th says:—“There are four reasons why every physician and every other good man should wage persistent war against unnecessary noises:

1. Because in a certain and an increasing number of sensitive and “well” people such noises distinctly and in carrying them over the easily passed line between comparative health and the sick and “unfit for service,” thus surely increasing the sick-rate.
2. Because they decidedly destroy the vital and restorative powers of the sick, and thus clearly increase the death-rate.
3. Because they dull and brutalize the nervous systems of those who can and do learn to withstand their pathogenic influences.
4. Because they serve to make the sensitive and cultured, who are able to do so, separate themselves in their search for quiet from the masses, who must endure, thus serving to intensify the license of the noise-makers, by lessening the checks upon their crimes. The separation of the community into classes in exaggerated in this way, and these, growing wider apart, make impossible desirable helpfulness, sympathy, and mutual understanding of each other. Noise is undemocratic; it should be un-American.

We endorse these sentiments and think that it might be well to begin with the suppression of the newsboy and the maddening cry of ‘Extry speshul! jyst saout.’”

Sterilization of Milk.

PROFESSOR FROSTER, STRASSBURG (British Medical Association meeting), said that one of the pieces of advice which hygienists gave was not to use milk from cows until it was boiled, not because the milk came from the animal, but because it could be contaminated by contact. Milk by boiling took a peculiar taste, the colour became yellow, and the general flavour of the milk was lost to a certain degree. Many people, therefore, did not like boiled milk. The question was, therefore, was it necessary to boil the milk in order to kill the germs of disease which were in the milk?

The process used was Pasteurisation of the milk. But this as ordinarily carried out, was insufficient to kill all infective germs with which milk might be contaminated. Instead of raising the temperature of the milk to 150° F. or 160° F. for one minute, it should be kept for a long time at that temperature. The flavour of the milk was retained, and in no way altered by the treatment. This process has been adopted by the milk companies in Amsterdam.—*Treatment.*

Legal Relations of Mania.

Dr. EDWARD C. MANN says that it is important for the lawyer to bear in mind the following points relating to mania:

1. In mania, consciousness, memory, and reason may remain intact even in the midst of the most violent paroxysms. The patient is whirled about in an emotional storm.
2. The maniac's senses are deceived and confounded. Illusions and hallucinations of sight are very common.
3. The persons with whom the insane man associates are apt to derive their characters from his delusion.
4. Real impressions on the organs of sense become, as in dreams, the materials of imaginary scenes.
5. The strange antics of the insane man are the effects of his delusion.
6. The violence of the madman is often not the effect of mere passion, but of his delusion.
7. The maniac, if of a reserved disposition, or when impelled by a strong motive, can conceal his delusion.
8. The acts of the maniac often evince the same forethought and preparation as those of the sane.
9. The maniac, in spite of his cunning, is easily imposed upon and managed.
10. Maniacs in confinement are often conscious of their state, and know the legal relations in which it places them.

In deciding medico-legal questions, it is quite necessary to know that these are some of the leading characters of mania.

The lawyer should be aware of the fact, which at times is of considerable medico-legal significance, that mental disease may arise as a result of the revolution in the system of either sex occurring at puberty. Masturbation also causes it; uterine or ovarian disease likewise. The condition of gestation or pregnancy may give rise to it. Mental disease may appear after parturition, when it is termed puerperal insanity, and it is not at all uncommon in a mild form. Obscene words and self-accusations of impropriety and delusions connected with sexual matters are all common at this time. The period of lactation may be associated with mental disturbance. The climacteric period in women not uncommonly gives rise to nervous troubles which may end in insanity. Insanity may be among the sequelae of fevers. The rheumatic and gouty poison may cause insanity at times. Syphilis and phthisis may both give rise to and be associated with mental disease, and alcoholic insanity is very frequent, and is accompanied by hallucination of hearing and other hallucinations. Finally we have the insanity of old age or senile dementia.—*N. Y. Med. Jour.*

THERAPEUTICS AND PHARMACOLOGY.

Purgatives and "Debility."

WITH respect to purgatives, there has not been that extreme variation in practise which has obtained with regard to some other remedies; but I think, notwithstanding, that the fashion of late years has been to neglect them *far too much*, although in one form or another they are perhaps the most universally applicable, and certainly among the most potent and most useful, remedies we possess. The abandonment of their employment is excused, one hears again and again, owing to the fear of their producing "debility."

I believe that few words in the English language have produced so much harm as this word "debility." Debility seems to be the *beau noir* of the present medical world. Men speak of it as if it were an entity instead of its being, as in fact it is, an effect—a result; and it was often to counteract this state that, a few years ago, stimulants were so widely given. It is disease which produces debility, and if these purgatives remove the morbid state, they often prove the most strengthening as well as the most healthgiving of remedies. "Talk about champagne," said BYRON, in one of his letters, "there is nothing which cheers your spirits up like a dose of Epsom salts." And, in a sense, he was right. Seriously speaking, sulphate of magnesia is one of the best forms of saline aperients, and the old-fashioned stock medicine of the surgery and of hospitals, the "Mistura alba," has more cures due to it than will ever be achieved by a dozen of the new fashioned remedies which have lately inundated the advertising pages of our journals. I say that Epsom salts have gone out of vogue, but a tacit compliment is, notwithstanding, constantly being paid to them, for people still find the efficacy of the solutions which contain them, and they take our old friend in a more expensive form, under the names of FRIEDRICHSHALL, HUNYADI JANOS mineral waters.

I am quite aware of the experiments by which it has been proven, or said to have been proven, that mercurials are not cholagogues. Well, I cannot discuss that matter here; but this I know, that a good dose of calomel or blue pill, given in the olden fashion, and followed by some sulphate of magnesia or other good saline purgative in the morning, will bring away copious motions of yellow, green, or black matter such as you do not get otherwise; and one feels, after that, light and buoyant and bright, and with a head clear for work—a state such as one has not felt in, perhaps, for weeks before: the melancholy—the black bile—has been removed. CHARLES J. HARE "Good Remedies—Out of Fashion," in *The Prac. Med. Age*.

Restoration of Bleeding and Indications for Venesection.

THE *Journal des praticiens* for July 9th says that at a time when the masters of French medicine are labouring for the rehabilitation of bleeding, it is interesting to note that an analogous campaign is being carried on abroad. According to M. KACZEK (*Wiener klinische Rundschau*), the principal indications for phlebotomy are: 1. Among diseases of the nervous system, meningeal inflammations, cerebral congestion, and apoplexy furnish positive indications. 2. In diseases of the kidneys, with generalized oedema and with uræmic symptoms, bleeding acts in two ways—namely, as a depleting process and as a sudorific. 3. In circulatory troubles consecutive to cardiopathies, it unloads the venous system and augments the arterial tension. 4. Its efficacy in pneumonia is remarkable. It should be had recourse to at the outset. It eases the patient by suppressing the pain in the side and rendering the respiration and

circulation freer. It diminishes also the engorgement and pneumonic exudation. If the heart should ultimately flag there need be no hesitation in repeating this little operation. 5. In chlorosis, one or more bleedings at from four to five weeks' interval are a sovereign remedy. The more the blood is altered, the more is bleeding indicated. A simple method of appreciating the alteration of the blood without the hæmatoscope and the hæmatometer, which are but little used, is as follows: Some cubic centimetres of blood are collected in a straight tube and allowed to remain for twenty-four hours; two thirds should then be occupied by the clot, above which should be seen a fine red layer composed of leucocytes, while the upper third is occupied by serum of a straw-yellow color. The more the appearance differs from this type the more the blood is altered, and the more is bleeding indicated. We fancy this new propaganda will find the invincible prejudice of a large mass of heathen very difficult to overcome.—*N. Y. Med. Jour.*

Thyroid and Thyroid Therapy.

HALDOR SNEVE, in the *Northwestern Lancet*, concludes a resumé of our present knowledge of this subject, as follows:—

1. The thyroid gland produces a secretion of the greatest importance to the metabolism of the body. Absence of function produces cretinism, if congenital; myxedema, if acquired.
2. Simple hyperplasia (simple goitre) does not produce marked pathological disturbance, but he believes it to be a larvated form of exophthalmic goitre. So-called "nervousness" can be found in the vast majority of these cases.
3. Hyperplasia associated with disturbance of the cervical sympathetic is the disease known as exophthalmic goitre.
4. Surgical interference in diseases of the thyroid gland should be limited to the removal of neoplasms; thyroidectomy in exophthalmic goitre is unphysiological, irrational, and dangerous.
5. In the majority of cases of exophthalmic goitre, medicinal and hygienic treatment, rest, galvanism through the neck (2 to 5 M.A.), tonics, sodium phosphate and thymus gland will effect amelioration. In cases refractory to medical treatment, where life is threatened, section of the cervical sympathetic should be practiced.
6. Many cases of neurasthenia are cases of masked exophthalmic goitre, and should be treated accordingly.
7. Thyroid therapy is specific in sporadic cretinism, myxedema and simple goitre, and removes obesity.
8. Thyroid extract increases the unpleasant symptoms in exophthalmic goitre, and is a reliable test in the masked form of this disease.—*Pac. Med. Jour.*

Alkaline Treatment of Eczema.

THE *Journal des praticiens* for 30th April attributes the following formulæ to Brocq:—

1. R Sodium benzoate ... 2 to 5 parts;
Sodium bicarbonate ... 12 "
Syrup of fumitory, }
Syrup of gentian, } each ... 150 "
Syrup of saponaria, }
- M. S.: From two to four tablespoonfuls daily.
2. R Sodium bicarbonate ... 7½ grains;
Lithine carbonate, } each ... 3 "
Lithine salicylate, }
Carbonic-acid water ... 4,500
- M. S.: Two glasses daily.

—*N. Y. Med. Journ.*

A good General Tonic.

- R Strychnine sulphatis ... gr. ʒss
Acid phosphoric bibuli ... mʒv.
Ferri phosphatis ... gr. i.
Quinine bisulphatis ... gr. i.
Glycerini ... 3 ss.
Elix. aurantii ... q. s. ad 3 ss.
- M. et ft. solutio. S. Take before each meal.

—WINSLOW ANDERSON.

Correspondence.

THE PLAGUE IN INDIA AND THE LOYALTY OF ITS DOMICILED BRITISH POPULATION.

TO THE EDITOR, "INDIAN MEDICAL RECORD"

SIR,—That doughty champion of Freedom and Justice, the *Bangal Times*, writes as follows under the heading of of "Plague and Loyalty":—

"Two questions, with apparently small and indirect connection between them, have been raised by our talented medical contemporary of Calcutta—*Indian Medical Record*. We allude to them as *apparently*, because a first glance fails to disclose their relationship, but a closer inspection betrays that they have something in common in certain exceptional circumstances. Our contemporary's article strives to establish a link between an alleged pestilence supposed to have visited Calcutta within this year, and Anglo-Indian loyalty; and we admit his endeavour has not failed. Plague and loyalty are abstractedly estimated to be as wide apart, as north and south, but viewed in a light that suggests ties of association, they wear a different aspect. Firstly, it is consistent with our object to ask if, at any time, this year, Calcutta has had a plague visitation, and, we believe, taking Calcutta's population as a whole, an affirmative reply will not find ready acceptance. Decidedly, our contemporary holds that a negative theory would meet with far more general approval, and we agree with him. He observes:—

"We have consistently maintained that Calcutta has not had a visitation of true plague. We say "true" plague, because every standard work on Scientific Medicine defines plague as a contagious endemic disease," and this Risley plague (there is no other name for it) has been neither contagious nor endemic."

Hence, then, whatever else it may have been, Calcutta's visitant has not been true plague, unless, indeed in a disguised and attenuated form. It was sporadic, and its fatal effects manifested themselves in so insignificant a proportion, that, to call it a plague, would be an absurd misnomer. Yet, we cannot close our eyes to one scathing fact, that official opinion favoured its entity, and it is but courteous to allow that expert testimony, even when State-subsidised, is not unentitled to a certain amount of respect. If we admit it exists, and that it opposes itself to widely-recognised non-official talent, we may feel that some covert impulse is at work, checking its full exercise, but its presence must be acknowledged, if only in a latent condition. Upon its value, however, we are not sufficiently technical to advance any judgment. Our contemporary says:—

"Judged by the clinical and epidemiological manifestations of the disease with which Calcutta was afflicted, Mr. RISLEY, one of the Secretaries to the Bengal Government, and a few of his State-paid medical advisers upheld his opinion that our city was plague-infected. Their prophecies regarding its spread have been as false as Balaam's and the opinion of the medical experts is so utterly disgraced and confounded, that, it does not find practical or logical support from either the clinical or the meteorological behaviour of the strange febrile disorder which they

terrifyingly, hailed as the **PLAGUE**. So that, from start to finish, this scare, created and fostered by State-officials, has proved itself to be a huge, unmitigated medical fraud."

How our contemporary contrives to institute a comparison between **BALAAH** and Mr. **RISLEY** and his councillors, we do not quite grasp, but we let that pass, with a slight suspicion that, having opened their mouths to rebuke those who differed from them, they might more appropriately be likened to—eh—but, as we have said, perhaps, it is better to slur over that episode. It is, however, beyond denial, that, their predictions, instead of curses have been converted into blessings, and that Calcutta has really escaped a scourge that might have decimated her. Our contemporary's language appears to us somewhat involved and inconsequential, but we hold with him entirely in his main contention, and it seems to us he is right in his insistence:—

"It is no disloyalty to speak the truth fearlessly, even though such expressions challenge the policy of the Government and lay bare its weakness and rottenness. It is false loyalty, disastrous alike in its duplicity and in its consequences, to betray the Government into a course of action that is positively dangerous both politically and financially, thereby divorcing the affections of the ruled and wrecking the reputation and prestige of the rulers."

Without doubt, such a course as our good friend decries, would be contemptibly dishonest, and fraught with results too lamentable to foresee, and too sad easily to avert; and it is clear that Government, in its so styled plague regulations, was seduced, by misleading representations, into a policy, which, whilst it was in force, compassed illimitable mischief. But we think there is something to be said in its defence. Government was hoodwinked, and displayed much infirmity of purpose, we will even allow, willingly, in some instances, yet we feel we cannot but admit that, its intention was good. It suffered itself to become blind and deaf, where it should have been vigilant and wary, still we think that it acted from indecision and hesitation to precipitate itself on the vicissitudes of what it deemed a growing calamity, without taking into its confidence—misbegotten, indubitably—those likely to suffer more severely in ignorance, than with a full knowledge of an impending and irresistible evil. Its act was incautious, and calmly viewed, unstatesmanlike, yet we think intended to be meritorious in its repressive prescriptions. Our contemporary concludes severely, though not altogether unjustly, and although we are far from an apologist for Government, we cannot but allow that, but for a panic injudiciously fanned into a despondency born of desperation, we should have had a far different experience to relate and far different sentiments to endorse. Our contemporary says:—

"We maintain that the *Englishman* and the Bengal Plague Commission are solely responsible under the misleading influence of medical men, who simply said what their paymasters bid them, that the whole commercial machinery of the metropolis was dislocated, its trade utterly paralysed, and the domestic peace and happiness of its European and Indian inhabitants wantonly disturbed for almost half-a-year. We are second to none in

our loyalty to the Government. The British Government of India is the greatest of Providential blessings in the destiny of this Oriental Empire, but, while admitting that this is so, we as frankly and as fearlessly declare that the policy of the Indian Government is not only misguided and wrong in its effect on the peace and welfare of the domiciled European and Indian communities, but it is from a sense of deep and earnest loyalty that we warn the Government that its treatment of these communities, more specially the domiciled Anglo-Indian community has created the intensest feelings of disaffection towards such policy, and it behoves a Government, if actuated by a desire to deal righteously and impartially with its subjects to disperse and eradicate the causes of such disaffection, as to do otherwise is to be unrighteous, unjust, and impolitic."

With a wearied brain, and a sick heart, we have impressed upon Government, from time to time, that its policy towards our domiciled Anglo-Indians is founded in error. Anglo-Indians can endure much—let their past brave deeds testify to that—and their inborn instincts of loyalty and fealty to our sovereign and to her constituted agents, have restrained them hitherto from any overt demonstration of discontent, any open and clearly emphasized expression that the tension upon their patience is greater than they can bear with impunity. What form their outbreak will assume, we do not know, nor need we speculate. Of this fact we are certain, that Government, by its policy of ignoring Anglo-Indian claims and by treating them with irritating contempt, is practically applying a slow fuse to a mine that will some day, we fear, explode with crash that will resound throughout her Majesty's Eastern Empire. It is useless, if not criminal, to conceal from our rulers that we are bound to have our rights—peacefully, if we can—and our aim is to obtain them through the agency of reason pleading for justice. Our pleas have already received technical recognition, in isolated instances of our members being singled out for important posts in State employment, such as imported talent could not be found to fill, and we are not unmindful of this admission of our superiority. We never sought it. Circumstances forced our **KELLNER** and **HOLLINGBERRY** and several others into notice, and into positions that earned for them a public declaration of their merits. There are many to succeed them, many to restore to India a share of patronage usurped by our India Office and Secretary of State; for them we are doing battle. There cannot be a particle of self-interest in anything we advance or advocate, as our day is past. Government cannot give us anything acceptable to our pride, but it can, and unless we stupidly over-rate our growing and strengthening resources, will, grant to our children, what the stress of untoward events has prevented our obtaining for ourselves. Government will do well to ponder over all this."

Yours &c., AN-ANGLO-INDIAN.

SOME MORE COMPROMISING CALCUTTA MEDICAL ADVERTISEMENTS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Since exposure of certain flaunting medical advertisements has already done some good, I hope a repetition of exposure in the *Record* will cause a few more of our offending brethren to hide their unworthy heads in shame. I therefore send you the following advertisements taken chiefly from the *Statesman* and other native papers:—

MAITRA & Co.

Homeopathic Pharmacists, Book Sellers, &c.,
45, 46: 47, 48 & 49, College Street, Calcutta.

Importers from Europe and America.

Under the Supervision of

Dr. B. B. Maitra, M.B.,

Late House Surgeon, Chandney Hospital, Calcutta.
Late Resident Accoucheur and Goodeve Scholar, Midwifery Ward, Medical College Hospital.

Price lists on application.

Specific for Chronic Malarious fever, Re. 1 per bottle.

Novelty of Ayurvedic Medicine.

AYURVEDIC PHARMACY,

18/1, Lower Chitpore Road,

Fouzdari Balakhana, Calcutta.

Kaviraj NAGENDRA NATH SEN, Member, Surgical Aid Society, London, Society of Chemical Industry, London, Paris Chemical Society, Calcutta Medical Society, and Indian Medical Association, Physician, Surgeon, Accoucheur, practices the Ayurvedic system of medicine after having obtained a Diploma at the final examination of one of the Government Medical Institutions of the country.

Specifics for all ordinary diseases like Fever, Cough, Asthma, Phthisis, Diabetes, etc., including disease brought on by irregularities of all kinds, Catalogues containing full accounts of diseases and remedies are transmitted on application. Prescriptions, with or without medicines, sent to every part of India and Ceylon, Cape Colony, and the British Isles, on receipt (by post) of full accounts of diseases.

Thousands of unsolicited testimonials from every quarter.

PHYSICIAN S. N. GHOSE.

Specialist in nervous debility, nervous weakness, nervous exhaustion, loss of tone in the blood. Rheumatism, Paralysis, Urinary diseases, Hydrocele, Scrofula, Liver and Spleen and also in Female diseases. Gold, silver, and other medicines electrically pulverized, and metallic liquid and oil (electrically prepared) for application, tested and analysed by an eminent European, and certified by Dr. DOYAL CHUNDER SHOME, Rai Bahadur, late Teacher, Campbell Medical School, are void of Mercury or any poisonous drugs. Wonderful effect within a week. Radical cure guaranteed, May be consulted at any hour at his house. No. 21, Wellington Street (Upper Flat.)

LAW & Co.

Homeopathic Chemists, &c.,
92, Bow Bazar Street, Calcutta.

DR. J. N. CHACKERBUTTY attends daily from 8 to 10 A.M. and 6 to 8 P.M. Cataract and other obstinate dis-

orders of the eyes are most successfully treated here. Best arrangements have been made for *Mofussil patients*. Particulars on communication. *Catalogue free on application*. Rubinis Camphor for Cholera, As. 12 per phial. Harry's Pillet, an infallible remedy for malarious fever. People tired of using other medicines should use it. Price, As. 8 per phial.

ELECTRO-HOMOEOPATHIC DISPENSARY.

First Established Mattei Agency in 1890. All our medicines are indented directly from Bologna in original tubes and phials. Experienced Electro Homeopath, Dr. R. P. DE, first authorised Agent, late of 93, Bowbazar Street, attends daily from 8 to 9 A.M. and from 6 to 8 A.M.

Electro-Homoeopathy aims at the very root of the disease, and therefore can cure even those maladies which are yet known to be incurable. Selected Books, Theobald Rs. 3-13; Gliddon, Rs. 3, Muller's Guide, Re. 1.

CHUCKERBUTTY & Co.,

34-1, College Street, Calcutta.

DR. B. L. ROY, C.M., Guarantees without the help of probe and knife, to cure Carbuncle, Liver Abscess, and any threatening Abscess; Necrosis, Sinus, Fistula and all bad Ulcers, etc. Roy Bahadur Dr. and Lall Dey, C.I.M., F.C.S., writes: "I state Necrosis which a cousin was suffering for years, pronounced incurable by Surgeon of the City, without operation, is cured by Dr. B. L. Roy, simply by external application. I safely recommend his able treatment."

Dr. B. L. Roy.

67-1, Nimitola Ghat Street, Calcutta.

Electric Treatment Rooms, 89, Beadon Street, Calcutta. Toothache and Painful Caries cured without extraction or pain. Organic weakness, Paralysis, Lumbago, Hysteria, Neuralgia, Rheumatism, etc., cured. Dr. ASHUTOSH GHOSH, L.M.S., late Resident Surgeon, Campbell Hospital.

KING & Co.,

The New Homeopathic Pharmacy,
83, Harrison Road, Calcutta.

Under the distinguished patronage of Dr. W. YOUNG, M.D., C.M., B. N. BANERJI, M.D., P. N. ROY, M.D., and all the other leading Homeopathic physicians of the country.

Just received an import of medicines, Books and Sundries per S. S. *Baravia*. We keep only the medicines of *Messrs. BOKKRE and TAPPEL of America*. Try them and realise their superiority to others. They are the cheapest because the best.

We have engaged the services of an able physician of the town who will send advice to patients in the *Mofussil* free of charge.

The Plague and its Curative and Prophylactic treatment by D. N. RAY, M.D., Price Re. 1. Correspondence solicited. Catalogue free.

HOWARD & Co.

48, Dhurrumtollah Street, Calcutta.

Consultation Department for General Diseases of Women and Children, etc. G. MANOOK, M.B., C.M. (Edin.), Physician and Surgeon, attends daily from 8 to 10 A.M. and 4 to 6 P.M. G. T. LEOPOLD, Personal Assistant to the

Late Dr. T. E. CHAWLES, Professor of Midwifery and House Surgeon, Midwifery Wards, Medical College Hospital, can be consulted at all hours.

It is quite true that some of these advertisers practice homoeopathy, but they should not flaunt their allopathic degrees. They are inconsistent. They have disowned their degrees, why further dishonor them. But some of these men have English diplomas. Can they not be reported to the General Medical Council?

Yours &c, L. R. C. P. & S., Edin.

CALCUTTA, 24th November 1898.

(We earnestly trust the Vice Chancellor of the Calcutta University will give expression to his feelings on the subject of medical advertising by graduates of the University, whose honor is in his keeping for the present. What can we say of a moribund Medical Syndicate which allows such misconduct to pass unnoticed. Men with British diplomas will soon hear more of their wrong doings M. I. M. E.)

—:—

THE TIMES OF INDIA ON THE PROSPECTS OF ASSISTANT SURGEONS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—As the *Indian Medical Record* is read by all high medical officials, I desire that you will very kindly publish the following article from the *Times of India* on the position and prospects of Assistant Surgeons:—"The recent concessions to the Assistant-Surgeons have shown that the Government of India are far from indifferent to the claims of the subordinate branches of the Medical Service. But they must go farther in the same direction before full justice has been done. A few weeks since we printed a letter in which complaint, as justified as it was bitter, was made regarding the passing over for promotion of the subordinates of the Madras and Bombay establishments who served in the Tirah expedition. Of the character of these men's service there can be no question. They worked in the thick of the fight at Dargai; they went through the trying Bara River march; they did their duty honestly and well in every engagement, taking their share of the dangers and hardships of one of the most arduous campaigns on record. We are told of individual cases of courageous performance of duty in rear-guard actions in which members of the Bombay establishment won the approval of all who saw their work. Those who have written in the interests of these men ask for no special recognition of their merits. What is asked for them is that, having done their duty as faithfully as others, they should not be treated worse than others. The list of promotions recommended and granted, which appears in a letter which we print to-day, shows distinctly that the Bombay and Madras men have been treated with marked unfairness. We take the number of recommendations as a safe indicator of the estimate which the officers in the field formed of the character of their work. By the side of this factor the most eulogistic reference to instances of individual devotion to duty are relatively of small importance. We find then that twenty of the subordinates in the Bengal establishment—one-third of the number employed—were recommended for promotion, and that of these twelve were promoted. Of the Madras men also a third were recommended—that is to say, four out of twelve. The Bombay authorities were more modest in their claim, for out of thirty-six doing duty they recom-

mended only eight. Neither Bombay nor Madras can, therefore, be said to have unduly pushed its claims. Perhaps, if the medical authorities in these Presidencies had asked for more promotions for their subordinates they would have saved them from being entirely passed over. However this may be, not a single promotion was given to either the Madras or the Bombay establishment, though a fifth of the number from Bengal who did duty with the expedition found favour at Simla. Unless there are reasons for this which have been kept from the public, this is an injustice of a 'peculiarly exasperating kind. It is well known that admirable work was done by men from the Southern Presidencies, and it is not known that the Madras authorities in recommending four out of twelve men for promotion, and the Bombay authorities in recommending eight out of thirty-six, were less capable than their colleagues in Bengal of judging of the number of deserving men whom their establishment had supplied for the campaign. It seems like suggesting a reason which ought to be no reason, but it is impossible to look at the strange table of promotions given by our correspondent to-day, without feeling that Bengal has done so well, simply because it is Bengal."

Yours &c, BOMBAY ASSISTANT SURGEON.

—:—

NEW IDEAS ABOUT PLAGUE TREATMENT.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—A new plan against plague has of late been adopted in the Baroda territory along with the usual measures, segregation, disinfection, camping out &c, and the result appears to be satisfactory.

There is a small town called Savali, (having a population of nearly 7000 souls,) at some distance from Baroda, where plague made its appearance in July last, and continued till October 1898. When segregation and disinfection had no effect on the epidemic, and camping out was not practicable on account of rain, pills (each containing quinine grs. 2, camphor gr. $\frac{1}{2}$, ipecacuanha gr. $\frac{1}{2}$, and carbolic acid m. $\frac{1}{2}$) were freely distributed by thousands as a preventive remedy. Each adult was asked to take two pills a day, one in the morning and another in the evening.

The people took to this measure kindly, as it did not at all interfere with their religious prejudices, and the result of it was remarkable. About the middle of September last (when the epidemic was at its height and the average daily number of cases was 82 from the 2nd to the 15th of that month) the pills were freely given and the disease began to decline rapidly. During the week ending on the 29th of the same month the daily average number fell to 4.4, and during the next week it was further reduced to .5. Subsequently there were in all nine cases from the 7th to the end of October 1898, since when no fresh case has occurred.

Some villages near Savali such as Sandhasol &c., were affected with plague, and there also free distribution of the pills produced the desired effect.

Sidhpour is a pretty large town with a population of about 16,000. A few cases of plague occurred there, chiefly towards the end of August last month, and the disease prevailed in an epidemic form in the next month, and continued like that in October 1898.

The total number of cases that occurred during the week ending the 4th ultimo was 71, and during the succeeding week it went up to 92, which was the highest weekly figure, giving a daily average 13.1. It was about this time that the pills began to be freely distributed; and the epidemic commenced to abate. Towards the end of the last month the daily average number of cases fell to five. In the current month it is still less, and since the 9th—there has been no fresh case.

Some villages in the neighbourhood of Sidhpoor became affected with plague, but free use of the pills checked it.

From what has been mentioned above, it would appear that the free use of these pills as a preventive measure against plague, deserves a further trial.

Yours &c., SHAMSUDIN J. SULMANI, L.M.,
Chief Medical Officer,

BARODA, 22nd November 1898.

THE WEEKLY RECORD.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—I was delighted to read in your issue of 1st November that the *Record* is going to be a weekly journal from January 1899. Owing to my official duties I can not find sufficient time, especially of late, to go through the fortnightly *Record* minutely, as I should like to do, but I still make it my duty, at any rate, to glance over the most important and interesting articles. Latterly to my joy I have been finding every issue of the *Record* replete with most interesting and useful information for any medical man with a fair knowledge of English, at least in my sphere of life, for I cannot say much about the feelings of people above my grade. Your excellent writings in the fortnightly *Record* do infinite good towards the advancement of the reader's medical and surgical learning and toward the improvement of his English, besides advocating the cause of the suffering members of the profession and advancing their interests. Judging from this how much more good the weekly edition will do? By this I simply express my feelings without the least idea of flattering or slandering any one; and I request that you will kindly give place to this in an early issue of your most valuable journal for the information of my co-professionists, and in order to awaken literary interests in those who may be hesitating to subscribe to the weekly edition for fear, that Rs. 1 or 1-8-0 per mensem will not fit into the means of all. They should consider the immense advantages accruing from such payments, for I strongly hope and believe that the future *Record* will amply repay the monetary help rendered to it.

Hoping time and space will permit the insertion of this in your much esteemed paper and heartily wishing every success to the weekly edition.

Yours, &c., W. CINDEKER,

DHARWAR, 19th November, 1898.

(We publish this single letter out of over a hundred that we have received from Hospital Assistants to show the kindly and appreciative spirit which pervades this whole class. It is remarkable how this ill-paid section of the profession has responded to the demand to convert the *Record* into a weekly. We heartily thank our Hospital Assistant friends for their prompt and kindly appreciation of our efforts.—Ed., I. M. B.)

QUACKERY AND QUACK ADVERTISEMENTS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—In your journal of the 16th November, page 415 and 416, is an editorial article headed "Quackery and Quack advertising in India." A portion of that article is devoted to an exposure of a pamphlet styled *Ayurveda Sangraha* in which various kaviiraji preparations are fully advertised. I am a kaviiraji practitioner, but I am also a Vernacular Licentiate in Medicine and Surgery of the Campbell Medical School, and by virtue of this qualification I became a Member of the Indian Medical Association.

I am well known to many of the leading Indian practitioners of this city, and acting on the advice of Dr. LAL MADHAV MUKERJEE and Dr. RAJRAJ DAS GUPTA I called upon you to show you my certificates as also to explain my position. I much regret that I have violated the etiquette of the medical profession, and I shall take immediate steps to put a stop to any advertisement which shows my connection with the medical profession. Having satisfied you and my medical brethren through your journal that I have a legal right to be considered a member of the medical profession, I shall leave my case in their hands. Trusting you will kindly publish this letter in an early issue of the *Record*.

Yours &c., NAGENDRA NATH SEN.

Government Medical Diploma Holder, Member of the
Chemical Society, Paris; Calcutta Medical Society;
Indian Medical Association, &c., &c., &c.
18/1, LOWER CHITPUB ROAD, CALCUTTA,
23rd November 1898.

(We have had a visit from Mr. Nagendra Nath Sen Gupta V. L. M. S. and have seen his government certificate of qualification which bears the signatures of the authorities of the Campbell Hospital Medical School. It proves that Mr. N. N. Sen Gupta is a properly qualified medical man, and it all the more justifies our condemnation of his advertisement. However, as Mr. Gupta promises to mend his ways, we shall cease to, refer to him in his indignant capacity as a medical advertiser and we sincerely trust other offenders will soon follow his present example.—Ed., I. M. B.)

Government Medical Gazettes.

GOVERNMENT OF INDIA.

The leave granted to Mily Asst. Surgn. E. J. Baptist, Med. Store Depot, is extended by six months.

Lieut.-Col. William McConaghy, M. D., to be Col. 25th Sep. 1898.

Asst. Surgn. and Hony. Lieut. Charles Pierce to be Senior Asst. Surgn. with hony. rank of Capt.

Asst. Surgn. William Archell Williams to be Senior Asst. Surgn. with hony. rank of Lieut.

Asst. Surgn. Arthur George Bowdler to be first-class Asst. Surgn.

Asst. Surgn. Reginald Henry Willick Hart to be second-class Asst. Surgn. from 2nd Sep. 1898.

Asst. Surgn. Joseph Nathaniel Hesterlow to be Senior Asst. Surgn. with hony. rank of Lieut.

Asst. Surgn. William Peter Bell Hart to be first-class Asst. Surgn.

Asst. Surgn. Charles Henry Arthur Alderton to be second-class Asst. Surgn. from 13th July 1898.

Asst. Surgn. Waldemar Herman Passanha to be second-class Asst. Surgn. from 7th Aug. 1898.

BENGAL GOVERNMENT.

Asst. Surgn. Preumber Mitter to do duty at Presy. Genl. Hosp.

Asst. Surgn. Mohendiro Nath Dutt to tempy. med. charge, Arrah Dispy., Shahabad dist.

Asst. Surgn. Nritto Gopal Mitter, Arrah Dispy., leave for three months

Asst. Surgn. Chunder Coomar Gupta, Burdwan Dispy., to act in med. charge, Monghyr Dispy.

Asst. Surgn. Surendra Nath Dutt, Lalbag Dispy., to act in med. charge, Chanchal Dispy., Malda dist.

Asst. Surgn. Sani Bhuvan Mukerjee, Chanchal Dispy., to act in med. charge, Tamuk Subdiv. and Dispy.

Asst. Surgn. Abhoys Kumar Sen, Tamuk Subdiv. and Dispy., leave for three months

PUNJAB GOVERNMENT.

Hosp. Asst. Abbas Ali Shah, to Jail Hosp., Peshawar, 31st Oct. 1898.

Hosp. Asst. Ghulam Ahmad, from Jail Hosp. Peshawar, to N.-W. Ry. Hosp., Nowshera, 2nd Nov. 1898.

Hosp. Asst. Muhammad Hayat, from N.-W. Ry. Hosp., Nowshera, Egerton Hosp. genl. duty, 7th Nov. 1898.

Hosp. Asst. Pir Bakhsh, Bannu, to retire from the service from 30th Sept. 1898.

Hosp. Asst. Harbans Singh to do genl. duty, Civil Hosp., Ferozepore, from 18th Oct. 1898.

Hosp. Asst. Harbhagwan from Miani to Khushab Dispy. 9th Nov. 1898.

Hosp. Asst. Bishan Das from Khushab to Miani Dispy. 11th Nov. 1898.

Asst. Surgn. Parma Nand, from Southern Panjab Ry., Bhatinda, to N.-W. Ry., Khanpur, 4th Nov. 1898.

Asst. Surgn. Lachman Das II, from N.-W. Ry., Khanpur, to Southern Panjab Ry. Bhatinda, 5th Nov. 1898.

Hosp. Asst. Abdulla Khan to do duty at Jholm from 12th Oct. 1898.

Hosp. Asst. Ganesah Das to do genl. duty, Civil Hosp., Sialkot, from 5th Nov. 1898.

Hosp. Asst. Harbans Singh, doing genl. duty Civil Hosp., Ferozepore, to Mehraj Dispy, Ferozepore Dist. and assumed charge 31st Oct. 1898.

CENTRAL PROVINCES GOVERNMENT.

Passed Med. Pupil Ramabhraya Jagannath Dube, doing duty under Civil Surgn. of Nagpur, is restored to the grade of 3rd Class Civil Hosp. Asst. from 18th Oct. 1898.

Hosp. Asst. Kabil Ahmad did duty under Civil medl. officer, Mandla, 18th and 19th June 1898.

Hosp. Asst. Ramchandra Krishna Chandorkar, Main Dispy. Balaghat, held charge of the Jail and Police Hosps., Balaghat from 11th to 22nd Oct. 1898.

N.-W. P. AND OUDH GOVERNMENT.

Asst. Surgn. Dalip Singh Katwal, Travelling Plague Med. Insptr., Allahabad Circle, to Plague duty at Hardwar, Saharanpur dist.

Asst. Surgn. Chander Mohan De. on Plague duty at Hardwar Saharanpur dist., to be Travelling Med. Insptr. of Plague, Allahabad Circle.

Asst. Surgn. P. N. Banarji, Chunar Dispy in Mirzapur dist., privilege leave for two months from 1st Nov. 1898.

Hosp. Asst. Narain Das, on Reserve duty at Pilibhit, Chunar Dispy, Mirzapur dist.

ASSAM GOVERNMENT.

Leave for one month, is granted to Hosp. Asst. Ananda Kisor Datta.

Hosp. Asst. Asvini Kumar Datta, Bhanga Dispy. in Sylhet dist. to Lushai-Hills dist. a supery. under Civil Surgn. from 20th Sept. 1898.

Hosp. Asst. Asvini Kumar Datta, a Supery. Lushai-Hills dist. to Champai Mily. Police outpost from 8th Oct. 1898.

Hosp. Asst. Mohendra Chandra Chakravarti, Champai Mily. Police outpost Lushai-Hills dist. a Supery. under Civil Surgn. from 17th Oct. 1898.

Privilege leave for three months, is granted to Hosp. Asst. Kailas Chandra Das, Tura Dispy Jail and Police Hosp., from 15th Sept. 1898.

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Re. 1 for subscribers and Rs. 2 for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTHS.

RAWA.—On the 24th October, at Tuticora, the wife of Dr. H. Bawa, F.R.C.S., etc., of the Ceylon Medical Service, of a son.

CAMPBELL.—On the 12th November, at Shillong, the wife of Lieutenant-Colonel R. Neil Campbell, M.B., I.M.S., of a daughter.

CAMA.—On the 13th November, at Bellary, the wife of Major R. H. Cama, I.M.S., 9th M. I., of a son.

MARRIAGE.

MEYER.—(COTGRAVE).—On the 9th November, at Matheran, by the Rev Davis, O.M.S., Captain Charles Hardwick Louer Meyer, M.D., B.S. (London), I.M.S., to Mary Scott, third daughter of T. M. Cotgrave, Esq.

DEATHS.

BOOKEY.—On the 7th November, 1898, at Abbottabad, Panjab, Stella, the infant daughter of Lieutenant-Colonel J. Bookey, I.M.S., aged 3 months.

BAPTIST.—At Madras on the 12th November, Assistant Surgeon E. J. Baptist, I.M.S.

CARROLL.—On the 10th November, 1898, at Meer Meer, Mary Josephine, the dearly loved wife of Assistant Surgeon Charles Carroll, I.M.S.

GUPTA.—At Calcutta on Wednesday, the 23rd of November, 1898, Dr. P. M. Gupta, Civil Medical Officer, Faridpur.

WEATHERLY.—On the 13th of November, at Kidderpore, Arthur John Weatherly, M.R.C.S. Civil Medical Officer and Planter's Doctor, son of Frederick Weatherly, of Faridpur, Somerset, aged 38.

NOTICES TO CORRESPONDENTS.

H. K. S. Your communications are always appreciated.

S. J. (Baroda).—Thanks, next number.

Eden Hospital.—We note Mrs. S's complaint that her nurse was sent to the Eden Hospital on the 19th November with a sick child, that she waited at the hospital from 11 A.M. to 4 P.M. without attendance, and was finally told that she could not be attended still 5 P.M.

Civil Apothecary. (Madras).—Officers of your designation are reckoned as belonging to the Assistant Surgeon class. They cannot be considered as being on a par with hospital assistants.

N. B. (Dagbhai).—Having attended to a case of miscarriage 10 miles from your station and having been detained for 24 hours, you as an Assistant Surgeon, should charge a fee varying from 100 to 150 Rupees. Each daily visit should be charged for at Rs. 24 plus travelling allowances, and if when in attendance with another doctor, you gave chloroform, you should charge Rs. 16 for this service.

W. C. (Wadi Junction).—We are very sorry we cannot help you in the way you desire.

A. K. H. (Poona).—You will find all the information you need in the Medical Register and Directory of the Indian Empire, and you will learn something further on the subject of your enquiries, in this and the last issue of the Record.

C. K. (Fao).—We regret we are not at all versed in Arabic.

A. B. C. (Deolali).—The papers you sent us are very creditable.

H. C. B. (Janai).—Your protest about Khaviraj N. N. S. Gupta needs translation. If you will have this done we shall be obliged. It is in Bengali.

Military Assistant Surgeon. (Karachi).—You are perfectly right when you say that a large number of the men of your class are positively apathetic concerning their own interests. You are further correct in stating that while they have enjoyed more special benefits than any other class from the existence of the Record, they are apparently the most ungrateful and unappreciative. It is perfectly true that the names of Civil Assistant Surgeons have come in in large numbers for the new weekly Record, while your comrades have shown marked lethargy in the return of the post cards sent them.

J. W. (Karachi).—The new scale cannot be altered and it is not at all too high for any class.

D. D. (Dinapur).—You will observe that British qualifications are necessary for the post you write about.

M. A. R. Thanks. Next number.

N. D. V. (Jettur).—We have nothing to do with the sale of the Medical Register and Directory of the Indian Empire. The entire financial responsibility of the above volume rests with Messrs. Barker Bros., Medical Publishers and Printers, at 150, Dharamtala Street, Calcutta. We can state frankly however that the cost of the publication to them has been very high, and they are not likely to reduce the price of the book.

Native States. We regret to observe that some Dispensaries, Hospitals and even "States" try to wriggle out of full subscription to the Record. Our rules for concessions refer only to individuals and not to institutions. We learn also of Civil Medical Officers buying the Record through and in the names of their Hospital Assistants. This is somewhat mean.

W. M. (Jubbulpore).—Kindly make out your case and send it with a copy of your service records and certificates to the Secretary, I.M.A.

ORIGINAL ARTICLES.

ON THE TREATMENT OF CARBUNCLE.¹

By THOMAS H. MANLEY, M.D.,
Professor of Surgery, New York School of
Clinical Medicine.

It is well-known that felons, erysipelas and carbuncle are most commonly observed during the spring and early summer. They all present many features in common, although the clinical distinction is clear enough. They often appear to be aroused into activity by some local change in the tissues, produced and maintained by what we vaguely designate "constitutional disturbances," but of which we certainly know very little.

CARBUNCLE.

MEREDITH defines a carbuncle as "a local specific inflammation of the subcutaneous areolar tissues, rapidly leading to sloughing of the deeper and more compact parts; followed by destruction of the skin, the whole of the dead tissues finally separating in the form of a slough."²

Carbuncle is a lesion which presents many very puzzling features. In all of its phases, as a rule, it is a very painful affection, in most instances commencing as a papule with an indurated base, assuming an intense inflammation, finally running into suppuration and gangrene, with later granulation and cicatrization of the ulcer. In this respect it is identical with whitlow. In other more aggravated phases the extent of constitutional disturbance is considerable; bodily strength rapidly fails and well-marked evidence of infection of the circulation is present.

In many cases of this class carbuncle kills. MEREDITH says that "death may come from exhaustion, which is sometimes aggravated by *hemorrhage, the result of free incision* [*italics mine*], but the most frequent cause of a fatal termination is pyæmia."

LOCAL CHANGES IN THE PARTS

Carbuncle kills, then, by the protracted, agonizing distress it occasions, which racks the system and cripples the vital powers; and by the toxic effects of resorbed dead tissues, ichor, pus and bacteria. This lesion gives issue to grave symptoms, only when certain local pathological changes set in.

How may these be aborted or rendered innocuous, or is either result possible? This brings us to the consideration of treatment.

TREATMENT: CONSTITUTIONAL OR LOCAL, PROPHYLACTIC, PALLIATIVE OR RADICAL.

Within the past year two notable essays on the therapy of carbuncle have been contributed by two distinguished members of the medical profession of New York; the first by Dr. L. DUNOAN BULKLEY, and the second by my colleague, Professor CARL BECK. Both of these contributions are noteworthy because of the extreme tendencies inculcated in each; by the former in the direction of conservatism and palliation, and by the latter in recommending early and complete excision.

EARLY EXCISION.

BECK says, "As the infiltrated tissue must be eliminated at all hazards, be it infected by whatever bacteria, it is

better to sacrifice it at once and to remove it with its disastrous inhabitants."³

Theoretically this position cannot be assailed; i.e., a limited focus of virulent infection of any description, wherever found, should be eradicated. But practically this is often either injudicious or impossible.

Anthrax, although its favorite site is along the lateral areas of the vertebral column, may develop on any part of the cutaneous surface of the face, the trunk, or the extremities. From our experience in excising chancres or buboes, it is well-known that before the stages of suppuration or ulceration it is impossible to determine just how wide the limit of invasion is; and, hence, quite in spite of a free dissection, suppuration will invariably follow, with a large, open breach in the tissues, left to heal by granulations. Again at times a wide area is involved by an infiltration which extends deeply into the neighboring parts, so that a free division of important and highly vascular structures will be necessary in excising the indurated parts.

In the incipient or papillary stages of carbuncle, excision affords us a simple means of at once and radically dislodging it, though we may have to repeat the procedure with each eruption of a fresh papule.

Finally, the most cogent objection one can bring against excision is that it may involve an operation requiring the employment of pulmonary anæsthetics, although when the area invaded is of limited dimensions a local analgesic will suffice; but in any event the tissues must be divided with loss of blood. It goes without saying that in carbuncles of huge proportions extending deeply into important structures it is quite impracticable. If anything like an extensive dissection be required, our patient must remain quiet until at least repair is well begun.

CONSERVATIVE TREATMENT.

At the late meeting of the British Medical Association in Montreal, Dr. BULKLEY, of New York, submitted a somewhat remarkable essay on the treatment of felons, boils and carbuncles, which, coming from one so well and widely known, must work incalculable mischief.

He begins by saying that "the knife has long been associated in the minds of both the laity and profession with the treatment of boils, felons and carbuncles, and incision is the recognized treatment on all sides." He declares that he has not incised a carbuncle in fifteen years, and adds that "if others will carefully and intelligently carry out the details in treatment, they will have equally as good results as himself." He advises the same general plan for felons and carbuncles. Now, it certainly would be an enormous gain to medical science if surgery could be dispensed with in a class of cases which practitioners have always regarded with serious apprehension, and which are sometimes a source of terrible torture and even danger to life.

Let us see what this innovation consists in. First, internal medication; the sulphate of calcium for its supposed controlling action on suppuration, purgatives, tonics, etc. Secondly, something locally, of a protecting, soothing and antiseptic character. The doctor quotes Paget as condemning the incision of carbuncle under all circum-

¹ Read before Society of Medical Progress, New York, March 20, 1898.
² Quain's "Dictionary," second edition, p. 274.

³ "Radical Treatment of Carbuncle." *The Clinical Recorder*, January 1, 1898.

stances. It is true that this celebrated surgeon severely criticized the indiscriminate cutting of carbuncles—the deep crucial incision—unless one was “certain of deep-seated suppuration; but that was nearly twenty-five years ago, long before the first days of Listerism had flashed on the horizon, and hence principles of treatment regarded as orthodox then are effete and antiquated.”⁴

KAPOSI declares that “treatment of carbuncle in its direct sense is almost powerless, as it cannot be cut short by ice, heat or early incision.”⁵ GUTHRIE advises “free and early incision followed by thorough curetting as of benefit in some cases, but complete extirpation is better.”⁶

Sulphide of calcium in my own hands has invariably proven inert as a pus destroyer; but what is of vital importance to bear in mind right here, is that, in the early stages of both felons or carbuncles there is no pus whatever. Several years ago the last phalanx of my little finger (left hand) was the seat of a felon. For three days and nights the agony was something dreadful. In the meantime various local remedies were tried, without the slightest relief. On the fourth day the physician was permitted to do what he wished to do on the first, viz., to sink the blade of a strong bistoury down deeply to the bare bone. The effect was instantaneous, but not a drop of pus escaped. Several times in the early and always the most painful stages of felons have I opened them with the same result. My experience has been that when pain ceases gangrene has begun, or the bone is necrosed. In genuine felon, true paronychia, which does not early abort of itself, penetration to or destruction of the diseased process beneath the periosteum, alone will save the affected joint or cut short the inflammatory changes.

It is inconceivable and contrary to all experience that any oleaginuous, impermeable or antiseptic substance can penetrate through the unbroken derma to reach the seat of disease. In fact, there are but very few medicaments which the skin can absorb at all.

That the constitution is involved in these cases is undoubted, and that bracing reconstructions are sometimes needed, is certainly correct. In advanced cases, however, the grave enfeeblement of the vital powers with marked evidence of pyæmic absorption is a consequence and not a cause. That glycosuria is anything more than a coincidence occasionally in carbuncle is by no means proven.

Sir JAMES PAGET is the authority for the statement that carbuncles sometimes spontaneously abort early. I have never seen one do so, and the probabilities are that the local induration described by him as carbuncle was some simple form of papillary intumescence. The tendency of unchecked carbuncle is toward progressive destruction of tissue, anpuration, necrosis and sloughing of tissue, with the great dangers superadded of septic infection, pneumonia, meningitis, etc. To dally with a lesion of such a serious character is, to put it mildly, a grave error. In the remote past, before the days of anesthetics or antiseptics, we did well to spare our patients the horrors of the blade for whitlow or carbuncle, until every possibility of mistake in diagnosis was eliminated and

the thing was “ripe;” but that won’t pass for up-to-date surgery in our time; for it may be, and it should be, stated in the most emphatic terms, that at the present, in both anthrax and felon, surgical interference must be prompt and radical, though, happily for the poor sufferer now, it may in the former spare him mutilation or the loss of even a single drop of blood.

POTENTIAL CAUTERY.

Moty reports a case of anthrax affecting the lower lip, with secondary foci on the breast, the forearm, and the shoulder, treated by puncture with Paquelin’s cautery at each suppurating orifice and subsequent dressing with carbolic acid. In some of the smaller foci the disease was checked at once by the puncture, and no more pus was formed. As for the deep-seated ones, the author remarks that the patient’s sensations are the best guide to their situation, for at first they do not betray themselves by physical signs; yet it is of importance to treat them promptly, whether pus has formed or not. The part may be cocaineized before the cautery is applied.⁷

In the early stages both of paronychia and anthrax they may be so effectively benumbed with cocaine as to admit of all necessary manipulation. The potential cautery, Paquelin’s or the electro-cautery, may be used with great satisfaction on many types of carbuncle not calling for total eradication and which are easy of access.

DIRECT, IMMEDIATE AND TOTAL DESTRUCTION OF THE CARBUNCULAR TISSUE BY THE DEEP OR HYPODERMIC INJECTION OF PURE CARBOLIC ACID.

Five years ago I commenced the treatment of carbuncle by the injection of pure carbolic acid. I am assured now that this method is simple, safe and durable in its results. To inject concentrated carbolic acid directly into the living tissues, however, may strike one as a measure fraught with danger, and is a measure which must be exceedingly painful. The first case of carbuncle which I tried it on came under my care in its acute inflammatory stages. It was the source of the most intense pain, with marked constitutional disturbance. The pulse was 116 a minute, the temperature 103° Fahr. Through loss of sleep and appetite my patient was reduced to great weakness. He had delayed professional aid till late, because of his fear of an operation.

In this instance the carbuncle was large, with several openings, lying over the midcervical region of the spine. In this instance the effects of carbolic acid injection were most extraordinary. Since then I have treated in both sexes more than fifty cases of carbuncle. About three-fourths of my patients were in hospital and dispensary practice. Five were physicians and three were physicians’ wives. There was no mortality, and in no single instance was there protracted delay in repair, except in those which came under my care late. Without exception when employed early this method arrested the advance of the boil, nipped it in the bud, so to speak, destroyed its root and branch, and, what is an enormous gain under these circumstances, permitted the afflicted to continue with comfort their ordinary occupations. CROCKER in his work on skin diseases notes that “it is said that a one to ten per cent. hypodermic injection of carbolic acid will abort carbuncles.” He does not appear to have had any experience with it himself.

⁴ Paget’s work appeared in 1873.

⁵ Kaposi “Skin Diseases” p. 317, vol. I.

⁷ Indian Medical Record, February 16, 1898.

LOCAL AND CONSTITUTIONAL EFFECTS OF THE DEEP INJECTION.

The first sensation the patient experiences after the needle is deeply lodged, is a burning heat from the crude acid. This is quickly followed by an immediate loss of all pain. The acid in places when it issues up blanches and chars the tissues, coagulates and destroys the purulent foci over a wide area. In the diminutive initial papule it also at once numbs all pain and stamps it out. The relief is so prompt and the destruction of infective spread so decisive, that the suffering patient again enjoys his unbroken sleep and recovers his appetite. And in this procedure we have an illustration of just the reverse of what is promised through constitutional measures, demonstrating as it does that the *fons et origo* of all the distressing and grave systematic disturbances of carbuncles are entirely dependent on a most virulent local septic process—a process which, if left undisturbed, proceeds to the total death of all the tissues invaded. In no instance in which I have employed these injections has there been any evidence of toxic effects on the system through absorption by the circulation, although it is possible that some of the salutary effects resulting may depend on the phonic elements acting on the system. This view derives some support from the interesting case recently reported by G. SCOTT JACKSON, M.D., of Glasgow.* His patient had anthrax, resulting from an infection of a sore on a sheep. The sore on the arm having attained great proportions, the whole limb being enormously swollen, JACKSON cut deeply down through the infiltrated mass, and then mopped the divided surfaces with pure carbolic acid. Besides, he immediately placed his patient on carbolic acid and iron internally, ten grains of the acid and ten of ferric tincture. From a desperate condition his patient was immediately relieved, with a subsidence of all the symptoms and rapid recovery. The writer believed the satisfactory result was attributable to the loss of blood after incision and the large doses of carbolic acid.

TECHNIQUE.

Before describing the details of the phonic injections for virulent abscesses it is necessary to state that they must be modified to meet the requirements of the various stages and types of the lesion. It may be well to bear in mind also that when utilized late, their most precious value is lost. The time for prevention, prophylaxis, has passed, and dead tissues cannot be recalled to life; but even when utilized in the advanced stages of the malady their value is infinite in arresting pain and checking the farther advance of disintegrating processes.

In employing this powerful agent let us be quite certain that we are dealing with a genuine anthrax, in order not needlessly to subject our patient to such heroic treatment for, perchance, an innocuous transient papule. Before we proceed to inject the fluid acid it is necessary first to carefully cleanse the surface, and then spray with ethyl chloride the part about to be punctured.

In my early experience I used the pure dissolved crystals of carbolic acid for injections, but later it was found that an eighty or ninety per cent. solution answered equally well. In all cases it is necessary to have a long and strong hypodermic needle, as the tissues are sclerosed and very resistant.

When an injection is made into a carbuncle in its early papillary stage, before extensive infiltration has set in, not more than from one to three drops are necessary. In all these cases, however insignificant the papule, after the acid has penetrated its base, coagulated pus will well up through its center. Care should always be observed that the surrounding integument be protected against the corrosive effects of the escaping fluid. Quite generally for small undeveloped carbuncles one injection will suffice; but, as we may miss the central "core," or infective focus, the first time, it may be necessary to repeat it once or twice, although this is unusual.

CARBUNCLE IN THE SUPPURATIVE STAGES.

After the multiple pustules of a large carbuncle have opened, its surface is raised high, and a wide reaching deeply inflamed zone surrounds it: the phenic-acid injection entirely dispenses with the need of incisions for the relief of tension and for drainage, as it totally destroys the imprisoned pus and the pyogenic bacteria which produce it. Pyogenic action extinguished, pain ceases and resolution begins.

In this class the acid must be injected with a free hand. In one case of a most aggravated description in the wife of a physician, into the enormous mass over her back I repeatedly injected as much as thirty drops each time. In carbuncle of massive proportions or great depth the fluid must be sent into the base.

Here caution must be observed, if we are operating over vascular areas, not to pierce the walls of a vessel and send the toxic charge into the general circulation. It is equally important to clear the large nerve trunks.

In most ordinary cases in this suppurative stage from fifteen to thirty drops are ample completely to destroy all purulent foci. But one needle puncture is needed through the integument. After a few drops are deposited at one point, the needle is partly withdrawn, to be sent in again in a different radius after being turned on its axis. This is repeated until the whole base is thoroughly cauterized.

AFTER-TREATMENT.

When this method is employed as a prophylactic early, there is practically nothing further to do, other than to keep the surface protected until charred center, the slough, is detached and thrown off, when complete healing quickly follows.

In large suppurating anthrax, carbolicization stays its progress only: the extensive gangrenous sloughs must be thrown off by a slow process of ulceration. At times a large hiatus is left to close in by granulation. Here complete cicatrization is sometimes very tedious because of the septic state of the system and want of plasticity in the blood. During the separation of the slough the patient should be freely stimulated and strengthened by the bitter tonics, iron, etc., conjoined with nourishing food. In severe cases the heavy wines and malted liquors are highly useful.

TYPES OF CARBUNCLES NOT CALLING FOR ACTIVE SURGICAL MEASURES.

Sir JAMES PAGET pointed out two very important features of carbuncles which it is well carefully to bear in mind when radical measures of treatment are being contemplated: 1st, that heavy carbuncles tend to spontaneous disappearance in their early stages; and 2d, that many do equally as well without the incision as with it, although he

* *Lancet*, 5th March 1898.

did not deny that the scalpel has a place in all deep-seated suppurating cases.

And so would my experience lead me to advise nothing other than palliative measures in any instance when there is absence of pain; but pain is an essential clinical constituent of any true carbuncle. If it be but transient and trivial, the sore should be let alone, or treated by simple measures; certainly by no aggressive surgery. Such a case I lately saw in the sister of a physician. The carbuncle was situated on the buttock; though freely suppurating it was quite painless. With moist dressings and compression repair was quite rapid and complete.

CASES SUITABLE FOR CONSERVATIVE OR NON OPERATIVE TREATMENT.

Pseudo-furuncle or carbuncle, those painless papillary projections from the cutaneous surface which occasion no inconvenience and make no impression on the system, should be treated with placebos or simple remedies.

For some reason, yet a mystery, even a malignant ulcer may continue its ravages without any pain; and so sometimes one may resolutely convince himself that he has no severe injury, though the head of a bone is luxated or a shaft sundered, because he endures no sufferings. In certain individuals a suppurating, sloughing carbuncle causes no pain or marked soreness. Generally with this class there is but little if any severe constitutional disturbance.

With the above class Dr. BULKLEY's line of treatment may be adopted with advantage, because it obviates mutilation and seeks to eliminate the *materia morbi* from the system. As between excision and phenic congelation for reasons set forth, the painless mummification should be quite generally adopted.

WHAT SHOULD THE GENERAL PRACTITIONER KNOW ABOUT THE EYE?*

By CARRION D. WECOTT, M.D.

Instructor in Ophthalmology at Rush Medical College, Etc., Chicago.

WHEN most of us were students, our good friend and faithful teacher, Professor HOLMES, believed that every physician should be able to recognize the commoner diseases of the eye, and that those who practiced in the country, or in small cities remote from specialists, should also hold themselves in readiness to treat such conditions wisely and with skill. He therefore gave us minute instructions for the recognition and treatment of diseases of the lids, conjunctiva, cornea and iris, and told us how to recognize cataract, and to know when it was ready for operation. He did not advise us to operate upon the eye except in actual emergency, and we were not instructed in the use of the ophthalmoscope.

Rush Medical College has never attempted to make specialists, but has done her best to prepare her graduates for the practice of general medicine and surgery. We, who are honored in calling her Alma Mater, are proud of the fact that she has never ceased her efforts to do more and better work each year.

Recognizing the growing importance of our knowledge of the eye in its relation to general diseases and conditions,

and the fact that every physician should be able to make a functional examination of the eye, the faculty, at Dr. HOLMES' suggestion, established, five years ago, a practical course in ophthalmoscopy and refraction. Since that time every member of our senior classes has had an opportunity to acquire practical knowledge of the methods of examining the eye as to its visual power and its refractive condition, and of the use of the ophthalmoscope.

We have not intended or attempted to instruct the students in the fitting of glasses, to properly do which often taxes to the utmost the knowledge and skill of the specially trained ophthalmologist, but we have demonstrated for them the optical properties of the eye in emmetropia and ametropia, and have taught them how to recognize the different errors of refraction, and the principles involved in their correction. Likewise it has been impossible to show the students all forms of intra-ocular disease, or to give them the skill in the use of the ophthalmoscope which comes only with months of patient practice, but, with the aid of models, we have taught them to see and to examine in detail the normal eye ground, and have demonstrated with charts and plates practically all of the important changes one is apt to see.

Basing my belief upon the stand which the College has taken and my experience with our students, it seems to me that the doctor whom we hold responsible for the health of the family and whom we expect to be prepared to do all emergency surgical operations, except possibly in the very large cities, should also be prepared to make an intelligent and comprehensive examination of the eye, both with reference to its diseases and its functions. He should be able to do this for his own satisfaction as well as for the good of his patient; and in most cases an examination which any physician can easily make will enable him to determine in a few moments whether the patient needs to consult the distant specialist, or if his trouble can be safely managed at home. It seems to me beyond question that the family physician should know that a red eye does not always mean conjunctivitis simply, and that it may mean keratitis, iritis, cyclitis or glaucoma, and that total and incurable blindness may result from any of these conditions, except the first. It is possible to differentiate positively these conditions, and having made the diagnosis one can stand from under if he is not prepared to take all responsibility in case of a bad result.

The general practitioner should always be able to differentiate between cataract and opacity of the cornea, and blindness due to glaucoma or atrophy of the optic nerve. Perhaps I feel a little sensitive on this particular point, as I once travelled one hundred and seventy-five miles, and carried all the necessary instruments and appliances for the operation of cataract extraction, to find that the patient whom I had been sent for to operate upon had no cataract, but a leucoma of the cornea, the result of an old ulcer. As it was not even a favorable case for the improvement of vision by iridectomy, I travelled another hundred and seventy-five miles home again, having lost the better part of two days, and without a fee.

It is also possible to settle the question approximately as to whether headaches and other symptoms which we attribute to eye strain, are due to manifest errors of refraction or not, and it may often save a patient a long and wearisome journey, as well as considerable expense,

* Read at the Scientific Meeting of the Alumni Association of Rush Medical College and sent by the author for publication in the Record.

if the family doctor will interest himself in the simple devices which are employed for this purpose. As many of you are doubtless aware, eye strain is not due to errors of refraction alone, in fact the error of refraction may play a very small part in the production of the distressing symptoms in a patient who suffers from neurasthenia or who is from any cause over-sensitive or below par. I find that most of the younger patients who are referred to me for glasses are suffering as much, if not more, from depraved nutrition and faulty habits of life, as from actual ocular imperfections.

There are practically no perfect eyes. Absolute emmetropia is a curiosity, and if all astigmatics wore glasses, almost no one would be without; but it is fortunate that there are some who have sufficient physical health and nervous force not to be disturbed by the additional effort of accommodation which is necessary for the auto correction of these defects. If everything possible was done by the general practitioner for the cure of eye-strain without resort to glasses, fewer patients would be sent to the offices of the ophthalmologists.

Every physician should also know that strabismus always means defective sight and imperfect refractive conditions, and that the cure of strabismus does not consist merely in the restoration of the normal appearance of the eyes, but rather in the correction of the error of refraction, the improvement of sight and the restoration of binocular vision. All of this is absolutely impossible unless we can begin the treatment of these cases very early. I believe that their treatment cannot be commenced too early, and I will venture to say that if the management of these cases can be begun when the symptoms first appear, and carried out with patience and intelligence, more than seventy-five per cent. of the cases of convergent and divergent strabismus can be cured without operation. In this connection I hope that none of you will fail to read the excellent paper by my friend, Dr. GEORGE M. GOULD, of Philadelphia, published in the *Philadelphia Medical Journal* of 21st May. The conclusions which he has reached are so thoroughly in accord with my own experience that I cannot forbear quoting. He says:

"1. Positive squint, easily recognized by any one, needs immediate expert help to prevent fatal and permanent amblyopia.

"2. By alternately covering the eyes (the cover test) the physician may, at a very early date, detect beginning imbalance.

"3. By bandaging the good eye, and observing if the child can pick up, handle and touch objects accurately, one may prove whether a suspected amblyopia really exists or not.

"4. The earlier in childhood, and even during infant life, that amblyopia, muscle imbalance, or high degree ametropia is discovered, the easier the prevention of almost certain and irremediable ocular injury. The child may be too young to wear glasses, and still therapeutic measures may be instituted (temporary mydriasis, or blinder for the good eye, for example) that will prevent injury too great for recovery.

"5. Glasses, when required, must be ordered much earlier in life than is supposed possible or taught neces-

sary. If I had a child of two years of age needing them I am sure they would be ordered, and just as sure they would be not only tolerated, but welcomed, and most sure they would prevent great ocular, physical and mental injury."

Unquestionably the family physician should be able to manage cases of conjunctivitis in all its forms, and he should certainly understand the nature of blennorrhoea neonatorum, and appreciate the importance of carrying out in minute detail the modern treatment of this disease, which is responsible for possibly 25 per cent. of all blindness which exists in the world. Likewise he should understand the importance of all injuries to the eye, and the necessity for proper initial treatment. A foreign body in the cornea is frequently overlooked because no examination is made in the dark-room by means of oblique illumination and the use of the ophthalmoscope, and infection and inflammation results in the loss of an eye, which could have been saved without any difficulty had the true nature of the trouble been determined.

I quite agree with the teaching that only those who are qualified by especial training and experience should operate upon the eye, except in emergencies, but there are occasions when sight may be preserved by the prompt action of the surgeon who is first called, in a case of punctured wound of the eyeball. All who are liable to be consulted under such circumstances should hold themselves in readiness to restore or cut a prolapsed iris, and to preserve in an aseptic condition any clean wound of the eye. The general practitioner may not be prepared to do iridectomy in a case of acute glaucoma, but tension can be temporarily relieved, and perhaps the sight of the eye preserved until the ophthalmologist can be consulted, by simple paracentesis of the cornea.

It is hardly necessary for me to call the attention of this audience to the advantage afforded by the use of the ophthalmoscope in general diagnosis, for it is now universally recognized that this little instrument is indispensable to those who aim to learn all that can be known of the condition of the brain and nervous system, and it furnishes valuable confirmatory evidence of many diseases of other parts. Perhaps, however, you will pardon a few suggestions. Everybody knows about BRUHN's retinitis, and that disturbance of sight due to the lesions of this complication is sometimes the first signal of grave disease of the kidney. Somewhat similar changes in the retina frequently accompany diabetes, and some forms of choroiditis often furnish the only evidence of hereditary syphilis. Twice within the year I have seen monocular optic neuritis due to anemia, in which the condition of the eye first called attention to the grave character of the disease.

As you are all aware, optic neuritis or choked disc is a frequent sign of abscess of the brain, and the most constant symptom of brain tumor. Embolism of the central artery of the retina, or one of its branches, with its sudden blindness and characteristic eye ground, may give the first hint of important heart lesion. Thrombosis of a retinal vein, while not so easily recognized, is equally suggestive.

Examples might be multiplied indefinitely, but I do not wish to be didactic. It is my purpose, rather, to remind you once more, that the eye is anatomically a

part of the nervous system, and that : "The ophthalmoscope is of use to the physician because it gives information, often not otherwise obtainable, regarding the existence or nature of diseases elsewhere than in the eye. This information depends upon the circumstance that we have under observation : (1) The termination of an artery and the commencement of a vein, with the blood circulating in each. (2). The termination of a nerve, which from its close proximity to the brain, and from other circumstances, undergoes significant changes in various diseases of the brain, and in affections of other parts of the nervous system. 3. A nervous structure, the retina, and a vascular structure, the choroid, which also suffer in a peculiar way in many general diseases."

—:—

DR. MARSHALL ON VENEREAL DISEASE.

By WILLIAM HUNTLY, M.A., M.D., B.Sc.
Nussereabad.

PERHAPS the saddest phase in the various discussions on the U. D. question, which it has been our lot to read, is concerned with the attitude taken up towards the moral aspects of the question. We would not have even introduced this part, but that it is introduced in the contribution to this question by Dr. MARSHALL in the *Indian Medical Record* of 1st November. He writes : "With regard to the moral side of the question we leave this aside altogether," and then adds, "with the exception of pointing out, as has been done before again and again, that we are dealing with &c., &c., and further that moral methods have been tried and failed." We might add also that we have read rubbish like this before, not only concerning venereal diseases, but also about drunkenness and indeed against every reform ever attempted.

It would be interesting if Dr. MARSHALL would inform us when these moral methods were tried, to what extent they were tried, how long they were tried (e.g., as long as the U. D. Acts were given a chance and failed), and what moral methods. Perhaps Dr. MARSHALL is unaware that the highest Army authorities have issued instructions to their officers to set moral methods in the front. Perhaps he does not know that when he says "no one thinks of checking these diseases by moral means" and includes venereal in the category, that the very latest document is the ample recognition and admission that these diseases have moral relations. And we can assure Dr. MARSHALL that in the near future more earnest efforts will be made to enlist morals in the fight against this disease and the vice with which it is mixed up. There is even great promise in this initial movement towards moral reform, when we read what has been done under temperance reform. It is too late for any one to heed such vague and loose statements as those submitted by Dr. MARSHALL. The question by the latest official military document on the subject has passed from being one of disease and sanitation, to being at its root a moral one. The pity is that it was not thus admitted long ago.

Dr. MARSHALL shows or tries to show a very fine appreciation of the differences of expression between Mr. WILSON and the *Lancet*. He finds fault with Mr. WILSON saying that, "The *Lancet* is conscious of complete failure." Would we direct Dr. MARSHALL to again weigh the meaning of the words of the *Lancet* quoted by himself.

The words ran thus,—*"There can be no doubt that the results were disappointing,"* and then adds the *Lancet*,—"the whole system should be amended and reconstructed." That reads plain enough. The whole system was disappointing, so much so that the whole system needs reconstruction. This certainly does not spell success. A new lock, a new stock, and a new barrel, before the old gun is fit for use ! Somehow we prefer a new gun. Remember that it is the whole system. That was the verdict. Is it likely that a fragment of that system at present being tentatively tried in India, will succeed where the whole system disappointed.

It is not worth while criticising in detail the statements of Dr. MARSHALL. We have at hand a volume of notes on the treatment of gonorrhoea by the late Sir Geo. MACLEOD, and these notes were taken before 1885. We have also a volume of treatment dated 1896. If Dr. MARSHALL will write out a statement of the great improvement in treatment between 1885 and 1895, which seems to him to explain most things, we shall be pleased to submit without alteration these old notes, and our readers can judge for themselves of the wonderful improvement in treatment, and what it all amounts to.

We shall also be pleased to learn how very modern our ideas have grown in the matter of the treatment of syphilis, and for that part of it, so also will the readers of the *J. M. R.* be glad to have the benefit of the modern ideas, on which Dr. MARSHALL puts such emphasis.

If Dr. MARSHALL agrees that hundreds are misled by Mr. WILSON simply placing in columns the figures supplied by the army authorities, letting them tell their own tale and quoting from the *Lancet*, it is very certain that almost no one will be misled by his article and his explanations. His three reasons why the acts failed may satisfy himself ; they will not satisfy even those who attempted the system. He will have to go down a little deeper and more thoughtfully into the question on its physiological, sanitary and moral bearings, before he will be likely to produce anything seriously worth consideration."

—:—

AN OLD BUT SUCCESSFUL TREATMENT FOR PLAGUE.*

By J. V. RAMASWAMY NAYUDU, L. M. & S,
Medical Practitioner, Madras.

OF all places visited by this pestilence, countries near the Mediterranean suffered much earlier, more frequently and for a longer time. It is natural therefore to expect that experience gained there will be useful in throwing some valuable hints for combating the disease in our country.

It was with this expectation that I went over some books on the subject that I could lay my hands on, and I found that among the various drugs used, there was one which was very highly spoken of as having been largely used with great success, which struck me as deserving a trial here also. I therefore made it my purpose to bring it to your notice.

The drug I mean is OLIVE OIL which is said to possess both preventive and curative properties.

*A Paper read before the Madras Medical Association on 18th November, 1898.

Mr. BALDWIN, the British Consul at Smyrna, observed that out of nearly a million people who died of Plague in Egypt in the space of four years, there was not a single oilman or dealer in oil. Taking this hint he suggested unction with Olive oil as a protective against Plague. The method was first tried in 1792 when 22 Venetian sailors repeatedly annointed with the oil lived for five days with 3 infected persons (all of whom died), without a single individual catching the infection.

Three Armenian families consisting of 27 persons were saved from infection by adopting this precaution, though they lived in the same floor and constantly attended on Plague patients.

The nurses in the Plague Hospital at Smyrna were effectually protected against infection by this method.

On the 14th June 1819, in answer to a question from a select committee of the House of Commons, Sir BROOK FAULKNER, Physician to the forces at Malta, said that the military attendants at the pest hospital were protected against infection by wearing a dress of oiled silk.

In 1804, Sir J. MCGREGOR recorded in the medical sketches for the year that during the Egyptian campaign, all men employed in applying oil to the feet of camels escaped the Plague.

Mr. JACKSON recorded in page 46 of a book on the Commerce of the Mediterranean, that the coolies working in the oil stores at Tunis smeared themselves with oil, and that they were rarely affected when the epidemic raged in the city.

The oil was subsequently tried as a curative in the early stage of the disease and found to answer well ; and for this purpose the oil was applied warm all over the body.

Though the preventive property of the oil was admitted by many eminent men, some were a little doubtful about its curative effects : even they unreservedly admitted that the abundant perspiration which it undoubtedly produced, was conducive to recovery in no small degree by expelling the poison.

Mr. JACKSON, in his account of a very destructive Plague which prevailed in Morocco in 1719, recommended this oil to many, both as a preventive and curative. He said that the oil was eminently successful in both capacities.

Here is something more *authoritative* and *emphatic*.

The Rev. LEWIS of Pavia, Chaplain and Agent to Hospital called St. Anthony's at Smyrna, after trying this oil for five years, pronounced it to be the most efficacious of all remedies made use of during a period of 27 years.

His directions were simply these:—

"Immediately after a person is perceived to be infected with Plague, he must be taken into a close room, and over a brazier of hot coals, with a clean sponge dipt in warm Olive oil, his body must be very briskly rubbed all over, for the purpose of producing a profuse sweat. During the friction, sugar and Juniper berries must be burnt in the fire, which raise a dense and hot smoke, that contributes to the effect. The friction ought not to be continued more than four minutes, and a pint of oil is enough to be used at each time."

"In general the first rubbing is followed by a very copious perspiration ; but should it fail of this effect

the operation may be repeated, first wiping the body with a warm dry cloth ; and in order to still further to promote perspiration, the patient may take any warm Sudorific drink, such as elder flower tea &c."

"It is not necessary to touch the eyes ; and other tender parts of the body may be rubbed more gently."

"Every possible precaution must be made use of, to prevent the patient taking cold, such as keeping covered those parts of the body not directly under the operation ; nor must the linen be changed till the perspiration has entirely subsided. The operation should be repeated once a day until evident symptoms of recovery begin to appear."

"If there are already tumours on the body they should be gently and more frequently rubbed till they appear to be in a state of suppuration, when they may be dressed with the usual plasters."

"The operation ought to be begun on the first appearance of the symptoms of the disease ; if neglected till the nerves and the mass of the blood are affected or a diarrhoea had commenced, little hope can be entertained of cure : but still the patient should not be despaired of, as by an assiduous application of the means proposed, some few have recovered even after diarrhoea had commenced."

It is a curious coincidence that the following passage occurs in the Bible and bears additional testimony.

"And they cast out many devils and annointed with oil many that were sick and healed them.—St. Mark.

"Is any sick among you ? let him call for the elders of the Church ; let them pray over him annointing him with oil in the name of the Lord"—JAMES. The oil referred to here was probably Olive oil.

Encouraged by the success which attended the external use of the oil in curing Plague, the oil was tried internally.

In 1820, two hundred persons were thus treated and the remedy was found to fail in 10 cases only.

Mode of administration was as follows:—

As soon as infection was caught (this probably means as soon as symptoms of the disease appeared) 4 to 8 ounces according to the strength of the constitution was given to the patient. This produced profuse sweating which seemed to expel the poison. The Sudorific action of the drug was aided by taking decoction of Elder berries (*Sambucus Nigra*).

The oil in some cases acted as an emetic, in others as a purgative, but profuse perspiration was a general rule and most favourable for recovery.

The efficacy of the drug was so great that the Moors who were generally averse to taking any medicine internally, especially for Plague, readily took to it.

In a village near Tangiera a father who had lost his wife and four children by Plague, adopted this treatment and saved himself and four other children.

To render the drug more efficacious, the oil was subsequently used both internally and externally, with the result that scarcely one instance occurred in which this double application failed.

A Spanish physician who had been upwards of a year in Africa, cured by this means almost all the Jews affected by Plague in Tangier.

Of the 300 persons attacked since the beginning of

1820 and who adopted this treatment, the malady proved fatal in scarcely a dozen.

In the same year the disease was prevalent also in the Isle of France (Mauritius) where of all the medicines tried the following was found most efficacious; 2 drachms of camphor dissolved in an ounce of Sulphuric ether and mixed with a bottle of Olive oil. Two table spoonfuls of this was given every half-hour. This was supplemented by abundant *mucilaginous* drinks. M. GALMAR treated 86 Negroes and cured 84 by this method.

The method of treatment is very simple. If a trial of this treatment here should result in success half as good as is mentioned above, it deserves in my humble opinion universal adoption.

My object in bringing this to your notice is that we should take advantage of the above facts and that a trial should be made of this method of treatment in the present combat against Plague.

The treatment may be improved in the light of the present state of our knowledge. If so, the combatants are at liberty to change their tactics.

I have reached the limit of the subject proper of this paper, but with your permission I wish to say something more.

Olive oil does not seem to stand by itself in the possession of the virtue mentioned above.

For:—

When Plague or a disease closely resembling it (known as Ghant-ka-roq) prevailed in the northern parts of India, Doctor McADAM has recorded that the people remarked those engaged in expressing oil were not liable to infection.—Transactions of Bombay Medical and Physical Society Vol. I. The oil spoken of here could not be olive oil.

When Plague raged in London, tallow melters and butchers were found exempt. The Esquimaux Tribes who regale on seal oil remain free. These facts seem to show that any oil nay, any fatty material is protective against infection.

It therefore struck me that Nim oil of our country, should be much more efficacious in this respect as it possesses well known antiseptic properties, and that the inhabitants of some of the villages in the north who are partial to this oil should be immune to Plague.

In the Theosophist for November 1898, it is mentioned that on the third day's Session of the annual Convention of the Theosophical Society, Doctor EDAL BEHRAM of Surat informed the members that he discovered a valuable secret of native doctors about Plague. He said that he had been working amid Plague about 2½ years, and had had charge of a hospital. He discovered that if one rubs his body all over daily with *sesamum* or gingely oil (*thilka tel*) impregnated with the juice of *Margosa* tender twigs and leaves, his fever, if he has any, will be lowered two degrees within an hour, and he will recover unless the disease has gone on to the most acute phase. He believes it to be also a prophylactic.

The *margosa* twigs and leaves must be bruised and their juice squeezed out. The juice must be strained and then mixed just as it is (without dilution with water) with an equal quantity of *Sesamum* or gingely oil. This must be boiled until the water of the juice is entirely evaporated, (which is known by ceasing of the froth and the surface becoming smooth). This must be bottled and kept tightly corked to prevent access of air.

Now this may be efficacious but the preparation is not as simple as it appears, for we cannot get tender *margosa* leaves in abundance except in Spring. The mature leaves do not yield much juice. Therefore why should not the seed oil itself be tried?

Native Physicians give the oil internally for many complaints.

The following is from (*Sarvoweshathi guna kalpam*). *Nimba thilum jayath kustam vrasa slashma juvarakrimoon.*

Nim oil will conquer leprosy, ulcers, fever, and diseases caused by worms.

I think Nim oil if tried will conquer Plague also.

DIFFERENTIAL DIAGNOSIS OF INFLAMMATIONS AND TUMOURS OF THE ILEO-CÆCAL REGION*

By P. SOUWENBURG, M.D.

As inflammations and some other affections of the gall bladder, liver, kidneys and pancreas as well as certain disorders of the female pelvic organs may so simulate appendicitis as to confuse the surgeon, the following points will be valuable for differential diagnosis.

Tuberculous infiltrations of the ileo-cæcal region may be distinguished from carcinoma and perityphlitic foci, by the history of the case, which often includes symptoms of stenosis, but fails to reveal the characteristic attacks of recurrent appendicitis. If however the appendix is itself the seat of tuberculosis the differential diagnosis becomes impossible.

Perityphlitic exudates like carcinoma are usually immovable, so to clear up any doubts about a movable swelling, inject the gut with air which cannot cause dilatation in the event of a new growth which stiffens the intestinal wall.

Investigation and various forms of intestinal obstruction may create doubts, but if there be tenesmus, bloody mucus in the stools, or complete obstruction of the bowel without passage of faeces or flatus, the probabilities are against the presence of appendicitis, which can also be distinguished from psoas, iliac or spinal abscesses, which are flat and non-projecting, while there are no peritonitic symptoms and the pain extends more towards the genitals and right extremity, when the thigh is flexed or rotated inwards.

Though diseases of the gall-bladder and liver are hard to differentiate from perityphlitic exudates, still patient enquiry into the history of the case will often determine the diagnosis. Thus in gall-stone or hepatic colic the (a) most painful point is close to the border of the ribs and the pain (b) shooting towards the shoulders causes (c) persistent vomiting, whereas in appendicitis the pain (a) which is greatest in the ileo-cæcal region extends (b) towards the navel and the (c) vomiting is not so persistent.

While there may be jaundice in both cases the tympanitic zone existing between the abscess and the liver in perityphlitic is absent in inflammatory or calculous disease of the gall-bladder, where the area of dulness is in direct relation with the normal liver dulness; but empyema of the gall-bladder and dilatation due to gall-stone obstruction are hard to distinguish.

Appendicitis may also be confounded with pelvic peritonitis, acute perimetritis, perisalpingitis and perioophoritis; but while the position of the exudate is of utmost importance, the lack of intestinal disturbance and the relations of the suspected tumour will point to pelvic troubles, though when the appendix becomes attached to the pelvic organs, the position of the tumour is of little help towards diagnosis.

In pelvic troubles the pains extend toward the genitals, rather than towards the epigastrium and the signs of diffuse peritonitis are wanting, while in chronic pelvic disease just as in appendicitis there may be acute recurrences; but in the former the symptoms are almost always markedly increased during menstruation.

Pelvic peritonitic exudates usually form in DOUGLAS' pouch and press the uterus against the abdominal wall. The uterine mucous membrane becomes congested and swollen, and the rectum excretes an abnormal quantity of mucus and exfoliates bits of membrane. In acute diseases of the adnexa, which are ushered in with vomiting and hiccough, the seat of the trouble is *ab initio* located in the vicinity of Poupart's ligament.

* Specially translated from the German for publication in the Indian Medical Record.

A MIRROR OF PRACTICE.

SUPPURATIVE RUPTURE OF A STRICTURED URETHRA : EXTRAVASATION OF URINE : PERINEAL URETHROTOMY : RECOVERY.

BY JAMES R. WALLACE, M.D., F.R.C.S.I.

Member, British Medical Association,

Formerly Resident Surgeon, Medical College Hospital, Calcutta, etc.

On the morning of the 24th October last, Mr. R.—, a Scotchman, aged 52, consulted me for a painful swelling in the perineum accompanied by an almost entire stoppage of urine. He had suffered from urethral stricture for several years. Six years ago he underwent partial dilatation by catheterisation, and obtained some relief for a few months. In March last the constriction returned and catheterisation was resorted to; but the patient suffered so much on this occasion, (while the smallest numbers which were tried and could not be passed into the bladder), that he relinquished treatment with the result that his urine dribbled from him constantly and gradually became more and more ammoniacal, causing intense irritation along the urinary passage. Latterly, about a fortnight before he consulted me, much increasing pain was felt in the perineum, and some swelling was noticeable in this part. On the 20th October, the patient got a rigor followed by fever. The urine became more intensely ammoniacal and the perineal swelling acutely painful. On the 24th the temperature rose to 104°F. the fever having been present since the 22nd, without any actual remission, and when I saw him that day I found on examination a hard, brawny, non-fluctuant swelling in the perineum, confined to the left side and stretching upwards into the left groin. No pus had been passed with the urine up to this time. I decided that the swelling was a threatening abscess due to extended inflammation from the stricture into the surrounding cellular tissue. I advised the patient to go to bed, which he did at 11 A.M. I saw him again at 9 P.M., and found the scrotum large, swollen and oedematous, with a similar condition of subcutaneous infiltration around the whole perineum, and left groin to within an inch and a half above Poupart's ligament. The penis was enormously swollen and dropsical. It was clear that rapid extravasation of urine was taking place, the temperature had risen to 105, the tongue was dry and red, the pulse rapid and intermittent, and generally the patient's condition seemed critical. I informed him of his danger, suggesting the urgent necessity of the operation of perineal section into the bladder, and free incisions into the extravasated area. With this object, I advised immediate consultation with Dr. HAVELOCK CHARLES, Professor of Clinical Surgery to the Calcutta Medical College. The patient was seen by Dr. CHARLES at 8 P.M. and he recommended perineal urethrotomy and the free incisions suggested. Accordingly at 9 P.M., after thoroughly asepticising the whole area, the patient was chloroformed by Dr. FELDSTEIN, and I opened the urethra in the middle line of the perineum. From this incision, urine escaped freely, and the distended bladder emptied itself through this vent. Free incisions were made into the left groin, penis and scrotum.

One out was fairly deep in the median raphe, and gave exit to some pus. The wounds were freely dusted with iodoform and boracic acid, and covered with iodoform gauze and boracic cotton, held in position by a T bandage. By 8 o'clock next morning much of the cedema had subsided and within another 24 hours it was gone entirely, and with it the fever too.

Urine poured from the perineal wound for four days only, and as it ceased, the urine was observed to trickle from the unhealed incision in the scrotal raphe. This continued till the parts were all thoroughly healed. On the 14th November, that is 21 days after the operation, it was decided to attempt an entry into the bladder by means of a No. 1 catheter. After much difficulty, I succeeded in doing this, and also in passing Nos. 2, 3 and 4 at the same time. Five days later I got No. 5 into the bladder, and by continued daily gradual dilatations, I managed to introduce a No. 12 on the 3rd of December. This number will be used twice a week for three months.

It is very interesting to note, that four days after I began catheterism, the fistulous opening in the scrotum ceased to have urine pass through it, and closed most effectually, so that not only had the patient recovered from a most dangerous and critical complication, such as extravasation of urine undoubtedly is, but also had his stricture relieved and practically cured. He also got rid of a very tormenting sequel in the form of a urinary fistula, (resulting as it did from the rupture of an abscess into his urethra), by the early resort to catheterism, which precluded the fistulous tract from assuming a chronic and incurable form, as it often does by inflammatory fibrous changes occurring in it.

—:O:—

ANTISTREPTOCOCCUS SERUM IN THE TREATMENT OF PRIMARY VENEREAL SORES AND THEIR COMPLICATIONS*

BY JAMES MOORE, F.R.C.S., Edin.

Delfaz:

WHETHER the chancre is an entity caused by the strepto-bacillus described by DUCREY, or an ordinary septic abrasion—the anatomical and physiological peculiarities of the genital organs accounting for the subsequent ulceration and complications—it certainly bears a very close relation to infection of a small wound by the streptococcus in any other region of the body. This analogy suggested to me that antistreptococcus serum might possibly have a curative effect on the chancre, and prevent suppuration (or liquefaction) of the acute inflammatory bubo so often accompanying it.

CASE I.—S. Y. consulted me on March 7th about pains in both sides over Poupart's ligament. He had had connection on February 28th, and on March 3rd noticed a sore in the coronal sulcus to the left of the frænum. On examination, I found four typical chancre, three having been produced by auto-inoculation, two glands in the left groin and one in the right considerably swollen and very painful; the outline of each gland could be easily felt, there being very little periadenitis. The patient informed me that the pain in the glands commenced about twenty-four hours before consulting me. I washed the glans penis in hot boracic solution, dried with pledgets of

* Reproduced from the *British Medical Journal* by request.

cotton wool, and sprayed the sores for ten minutes with peroxide of hydrogen. I then injected 1 drop of pure liquid carbolic acid into the base of each ulcer by means of a fine hypodermic needle and ordinary hypodermic syringe, passing the needle about one-eighth of an inch into the fissure. The ulcers were then dressed with a powder, containing ioretin and zinc oxide, equal parts. The skin over the lower part of the abdomen was disinfectant in the usual manner, and 5 c.cm. of antistreptococcus serum injected about an inch above and an inch to the outer side of each bubo, after allowing the patient to rest for about twenty minutes. A pad of sterile wool was applied over each point of injection, and kept firmly in place by a double apica bandage. I ordered the patient to bathe the penis for half an hour in as hot water as could be borne, and subsequently dress the ulcers with the above powder twice daily.

On March 9th the ulcers had a healthy appearance, the pain and swelling in the bubos had diminished. The patient said that for twelve hours after injection the region around the point of injection was painful. A scarlatiniform eruption was present on the lower part of the abdomen and inner part of the thighs. I inject 5 c. cm. into each side as before, and continued the local treatment of the ulcers.

On March 12th three of the ulcers had healed, and only the parent ulcer remained, and healthy granulations covered the entire base. There was no pain in the bubos, and swelling was scarcely evident.

On March 19th the ulcer had healed, and there was no trace of bubo. I have seen the patient twice since, and he continues in health.

During the past eight months I have used this method of treatment in 48 cases of acute inflammatory bubo, and in only 7 cases did suppuration occur. In 3 of these the inflammation had been in existence at least four days. I have also used this serum in the following case of phagedenic chancre.

CASE II.—On July 6th I was called to see B., who had been leading a very irregular life, in which alcohol played a very prominent part, for the past five years. He had a suspicious connection on June 4th, and on June 14th an ulcer appeared on the under surface of the glans penis implicating the frenum. From that time until my seeing him the ulcer had been practically neglected. I found the patient in a semi-comatose state, the skin dry and hot, the pulse 130, the temperature 104.3°F. On examination the under surface of the glans penis was entirely destroyed, and the urethra exposed. The discharge from the sore was offensive and sanious. The base was studied over with little patches of false membrane of a yellowish-green colour. On removing one of these a raw bleeding surface was exposed. The entire penis was swollen, of a dark-bluish colour, and presented numerous bullæ. The glands in the region of Poupart's ligament were not swollen. There was no rash on body or limbs. The fauces were congested. I ordered the penis to be immersed in a hot solution of mercury perchloride (1 in 5,000) for two hours, and twice daily; in the intervals iodoform was to be dusted on the ulcer, and the penis wrapped in gauze wet with the hot solution, and changed every twenty minutes. Into the right leg I injected with the usual precautions 10 c.cm. of antistreptococcus serum, and ordered him small doses of strychnine with tr. strophanthus, mv, every four hours.

On July 7th the temperature was 102°, and the pulse 120. The patient was brighter and answered questions more readily. There was no change in the ulcer. Some of the bullæ had disappeared from the penis. The right leg was red and swollen for about six inches above the point of injection. The inner side of the thigh showed a scarlatiniform eruption. The glands in Scarpa's triangle of the same side were enlarged. I ordered lead and opium

lotion to be applied to the swollen part around the point of injection, and continued the baths, etc., and general treatment.

On July 8th the patient was much brighter, the pulse was 105, and the temperature 101.5°F. The swelling in the right leg and glands had diminished. The ulcer showed much less false membrane, and the discharge was less sanious. I continued the general treatment, and injected 10 c.cm. of serum into the left arm.

On July 10th the pulse was 98, the temperature 100°F. and the general condition was much improved. The discharge was purulent, with streaks of blood. The false membrane had almost entirely disappeared, and the bullæ entirely. The penis was less swollen, and had a healthy appearance.

I was now at a loss to know whether the hot antiseptic baths to the penis, with iodoform to the ulcer in the intervals, combined with the general tonic treatment, or the use of the antistreptococcus serum was responsible for this happy result. I saw the patient daily for six days; did not inject any serum, but continued local and general treatment as formerly.

On July 16th the pulse was 115, the temperature 103°F. The penis was swollen and painful. The discharge from the ulcer was sanious. The base of the ulcer on clearing away the discharge showed numerous cup-shaped depressions. There was no extension of false membrane. I injected 10 c. cm. of serum into the right arm.

On July 18th the pulse was 98, the temperature 100°. The swelling and pain in the penis had abated, and the ulcer looked healthier.

On July 19th 10 c.cm. of serum were injected, and I gave 10 c. cm. of serum every third day up to July 28th. On that date I noticed two undoubted mucous patches on the left tonsil, and a few small papular syphilides on the abdomen, chest, and face. The temperature was 99°F., the pulse 82. The ulcer was one-third of its original size, and healthy granulations covered the entire base.

On August 1st the patient was convalescent, and taking small doses of mercury and iron.

I have to thank Dr. CALWELL for kindly advising me in reference to the condition of the patient's heart and lungs.

From my experience with antistreptococcus serum in venereal sores and their complications, I have arrived at the following conclusions:

1. While recognising the great importance of early local antiseptic treatment of the chancre, I believe that if 5 c. cm. of the serum is injected subcutaneously into each inguinal region in cases in which inflammatory bubo is likely to develop, it will prove a good prophylactic measure, and assist in healing the chancre.

2. If inflammatory bubo has already developed, and the acute inflammatory symptoms have not been present more than forty-eight hours, 10 c. cm. injected into the inguinal region corresponding to the inflamed gland will cause resolution in the majority of cases.

3. If there is evidence of pus formation the serum may possibly limit the extension of the suppuration, but in this class of case my results have been anything but satisfactory.

4. The serum should always be injected into the area drained by the infected gland, preferably the right and left inguinal region. I have not seen good results by injecting it into remote areas.

5. In phagedenic ulceration complicating venereal sores, this serum would appear not only to neutralise the toxins in the blood, but also to bring about a healthy condition of the ulcer.

Indian Medical Record.

16th December 1898.

THE THIRTIETH ANNUAL REPORT OF THE SANITARY COMMISSIONER FOR BENGAL, YEAR 1897.

II.

CHIEF DISEASES.

CHOLERA.

CHOLERA statistics may be accepted as fairly accurate. It was less prevalent during 1897 than during 1896, the mortality figures being 2.76, against 3.19 per 1000. Of the total 45 districts, there was an increase of cholera in 23 and a decrease in 22. Taking the 27 districts that were unaffected with famine, there was an increase in 15 and a decrease in 12.

That diseases such as cholera should fluctuate from year to year is surely one of those universally admitted facts which we all confess our impotence to explain; not so the report before us, red tape demands an explanation for everything, let us see what it is.

The Sanitary Commissioner has told us that the low death-rate "was due chiefly to the healthiness of the year, consequent on the exceptional dryness of the previous year," and again that it was "chiefly due to less cholera and fever," therefore the decrease in cholera was according to him due to the failure of rain in the previous year.

The Civil Surgeons however appear to hold the opposite view for we read, "The civil surgeons of other districts which were severely affected, attribute the outbreaks more or less to a deficient and polluted water supply, caused either by the scanty rainfall of the previous year or by the serious deterioration of tanks, wells and small streams by the upheaval of their beds by the earthquake of the 12th June. In some of the famine-stricken districts the epidemic is said to have been brought on by the people largely living on jungle products and other unwholesome food."

As the earthquake was pretty general, it does not seem clear why cholera should follow it in some places and not in others, and if it was a potent cause of cholera why was there a general decrease in the disease. As for the theory that cholera was due to the consumption of unwholesome food in the famine districts, it is met by the fact that there was an increase of the disease in the majority of the districts unaffected by famine.

DISINFECTING OF WELLS.

Some experiments were made on the effect of disinfecting wells by lime or permanganate of potash. Out of the 15 districts in which the experiments were tried, we are only given the results obtained in Lohardaga district and Ranchi town, these are extremely favorable, but not sufficiently extensive for the formation of any definite opinion.

ANTI-CHOLERA INOCULATIONS.

During the year, 10,950 persons were inoculated against cholera. We read that, "The record of results of inoculations is unfortunately incomplete like that of the preceding year," no doubt from changes, and an insuffi-

cient staff. Surgeon-Captain VAUGHAN who was in charge of this important work was sent on military duty on the 3rd August.

We read in one place that the inoculations are strictly voluntary, and in another that "Messrs. DRIVER and STAINFORTH and Mr. MATHEWSON, the principal forwarding agents in Parulia, are very particular to have every cooly inoculated before they are despatched." There is a suspicion of a disagreement between the two statements.

The general idea is that the inoculations are beneficial. With reference to Hazaribagh town and Central Jail where they were tried, Surgeon-Captain NOTT reports, "On the whole little is to be gathered, either favourable or unfavourable, from the inoculations performed in the Hazaribagh town and Central Jail" but then the virulence of the epidemic had subsided before they were begun.

SMALL-POX.

The death-rate from small-pox was .27 against .18 for the previous year.

FEVER.

The death-rate under this heading was 23.62 against 24.76 for the previous year and 19.81 average of the past 10 years. The statistics are quite unreliable. A death-rate of 23.62 is very high, but what the meaning of "fever" is no man can tell, in fact we are in entire ignorance of the nature of the diseases which cause the greater part of the mortality in the province of Bengal. With the possible exceptions of cholera and small-pox, every disease is to be found heaped together under the all embracing name of "fever."

That this is the case is freely admitted. Under the head of "dysentery and diarrhoea" the Sanitary Commissioner says that the number of deaths from this cause is larger than the number registered "many of these are erroneously reported under other heads of diseases (cholera, fever, and other causes) by illiterate Chaudikars."

The Civil Surgeon of Hazaribagh is reported as saying "No doubt a very large proportion of the over 40,000 deaths returned as from fever, more accurately should have been returned under this head, (dysentery and diarrhoea) though fever, whether symptomatic or really malarial, probably was a sufficiently prominent symptom to excite attention."

This being so, we think it is mere waste of time constructing maps and diagrams of the prevalence of "fever" in the different districts, and carefully tracing its fluctuations from year to year in different places with vast statistical details.

In discussing the question of fever we note that every argument is based on the assumption that "fever" is malaria, this assumption is by no means warranted.

We are grateful to the Sanitary Commissioner for giving us a map of Lower Bengal illustrating the character of the soil.

The soil of Lower Bengal is here divided into alluvial and older formation, a great belt of alluvium forms the valley of the Ganges; stretching south and west from Bhagalpur and Rajmahal we have the greater part of the older formation.

Time out of mind malarial fever has been held to be a disease of alluvial soil, and accordingly we would expect to find it more prevalent in the Ganges valley than in the older formation. A glance at the "fever" map will show

that this is not the case, the Ganges valley is not depicted as suffering unduly from "fever."

Puri, which shows the smallest amount of fever is alluvial, while Hazaribagh which is one of the districts showing the greatest, is in the older formation.

Pabna heads the list of "fever" mortality in 1897 and the Civil Surgeon explains it by saying that the increased prevalence of "fever" in the year may be attributed to the scanty rainfall. A variation in the rainfall appears to be a god send to these officials, when seeking for an explanation of anything unusual in the health conditions of their districts, it is a universal solvent suitable to the most diverse circumstances.

SANITARY WORKS (CIVIL).

Under this head we find :—"It will be seen that only 15 Municipalities spent over 10 per cent. of their income on original sanitary works against 17 in the previous year, while 37 municipalities spent nothing at all on this account as compared with 28 of the preceding year. It is disappointing to find that such important towns, as Raniganj, Hooghly, Bhadreswar, Balli, South Suburban, Berhampur, Noakhali, and Bettiah, did not devote anything for new sanitary works."

On page 57 we have a table showing the "effect on the public health of large and important sanitary works." For fear we should expect too much, we are told that, "As the registration of vital statistics was very defective prior to 1890, no definite conclusions can yet be drawn from the figures" in the table.

Examining the table we find that out of the 14 places mentioned, the statistics of which we are not told to distrust, the introduction of important sanitary works was followed by an increased death-rate in six.

This is not a result to brag about, and does not speak very highly in favour of the introduction of large and costly drainage and water work schemes.

In matters pertaining to sanitation it is always the old story of the leper king, the old hankering to do some great thing; we all know the extraordinary readiness with which Municipalities embark upon the most expensive projects, while things that appear trivial are slurred over or cast upon one side. Those important works once executed how are they looked after and supervised? An important side light is thrown upon this question, in so far as it relates to Lower Bengal, by the inspection reports of the Sanitary Engineer. These inspection reports are excellent in form and matter and offer the most interesting reading. Let us follow Mr. SILK in his inspection of the Bhagalpur Water Works.

These works were opened in 1887 and extended in the year 1897, the total cost has been Rs. 6,14,107, but the final bills for the extension have not yet been paid.

"At the time of my inspection" Mr. SILK writes, "the mouth of the intake pipe was entirely closed by an accumulation of brushwood and silt" "the form of the intake must be entirely altered."

"The practice of bathing above the intake has not been entirely stopped."

"The pumps of the two rotary engines have given considerable trouble during the year, owing to the suction valves not having been properly and regularly examined and repaired. The thumping and irregular working of these pumps is positively terrifying, and it has always

been a matter of surprise to me, that the pumps have not knocked themselves and the engine house to pieces long ago."

"No record whatever of the work done by the engines was being maintained by the Superintendent."

"The boiler houses were in an extremely untidy and dirty condition."

"At the time of my inspection the filter beds were in a most unsatisfactory condition, and no attention was being paid to the rules issued by the Sanitary Board."

"The general condition and appearance of the pumping station has been gradually deteriorating within the last three years," &c., &c.

Of the Mymensingh water works, filter beds, he says:—"The appearance of these was not at all pleasant as they were swarming with frogs and other aquatic reptiles."

The inspection report on the engines shows that every possible means had been taken to let them get out of order.

DACCA WATER WORKS.

Regarding the intake for the Dacca water-works we read: *The intake*.—"The following extract is taken from my report for 1896 :—

"In the report for 1894 attention was directed to the danger of mooring boats on the up-stream side of the intake, and in 1895 it was reported that a bye-law had been passed to prevent this. I regret, however, to have to report that, although a bye-law may have been passed, boats are allowed to moor above the intake just as much as ever. This is a very serious matter, for, as the case stands at present, the urine, sullage water, and not to mention night-soil, of the crews of 40 or 50 boats, pass down in front of the intake; these are mixed with river water undoubtedly, but it is almost certain that the suction pipe will draw in some of the diluted sewage."

"It seemed to me, at the time of my inspection, that so far from the mooring of boats in the neighbourhood of the intake being prevented, their numbers had increased, and to make matters worse the channel, into which the suction pipe dips, has much deteriorated from the advance down stream, of a large *chur*; the water-supply of Dacca is therefore at present derived from nothing more or less than a back-water of the river, heavily polluted by a large floating population."

FILTER BEDS.

"On enquiring what thickness of fine sand was in the filters, the Superintendent informed me that it was about 1' 7" or 1' 8", but when I came to dig up the sand in No. 1 filter, I found it be only 11"; the Superintendent has since reported that the thicknesses in filters Nos. 2 and 3 to be 1' 3½" and 1' 5½" respectively. The Superintendent's verbal statements have therefore been shown to have been unreliable. Filter No. 1, should be thrown out of work at once as the sand is much too thin and steps must be taken to bring the thickness up to at least 2'0" with freshly washed sand at a very early date. In the Sanitary Board's Circular No. 11, dated the 15th November 1894, it is stated that sand layer should never be allowed to get below a certain thickness of about 12", and further it is laid down on the rules for working filter beds in Bengal, rule 8, forwarded to the Chairman with Sanitary Board's letter No. 3538B, dated the 9th July 1896, that the fine sand in a filter bed should never be

reduced by scraping to a less depth than 12." I am really at a loss to understand why there should be so much difficulty in attending to very simple rules, so simple that they are quite intelligible to any non-professional man, and I consider it to be one of the duties of the Chairman and the Municipal Commissioners to visit the pumping station occasionally and see that these rules are being attended to."

These inspection reports, from which we have only quoted at random, form an overwhelming charge of the most culpable negligence in the administration of the important sanitary works, from which so much has been expected.

In conclusion, we append an extract showing the undermanned state into which the sanitary administration of Bengal was allowed to fall, owing to the paucity of medical officers on military duty in India.

"It will be seen that for half the year, which included the working season, there were no Deputy Sanitary Commissioners, all three having been ordered to military duty in connection with the disturbances on the North-Western frontier. There is, therefore, very little to show as to the work of these officers during the year under report."

QUACKERY AND QUACK ADVERTISING IN INDIA.

III.

Very closely allied to, and hailing from the same part of Calcutta (Lower Chitpore Road) as the "Ayurveda Sangraha" of Kaviraj NOGENDRA NATH SEN GUPTA, is the "Ayurveda Prochar" of MESSRS B. L. SEN & Co.

This is a pamphlet of 48 pages, it does not set up to be a *Medical Journal*, and is not adorned either with vile illustrations or fulsome press notices; it is simply a price catalogue of quack remedies with the usual unscrupulous lying statements as to their wonderful properties in all sorts of diseases. It also contains a large number of private testimonials.

We are told that this is "the Oldest and only Reliable Ayurvedic House in India," and that "it is under the direct supervision of a physician of vast experience and learning." The names of two so-called physicians appear, Kaviraj BINOD LAL SEN, and Kaviraj ASHUTOSH SEN. We need hardly remark that their names are not to be found in the Directory and that they have no claim whatever to style themselves physicians at all. There is a strong resemblance between the drugs advertised by these two firms, except that they go under different names, and it is fairly safe to assume that they are connected and carry on their nefarious trade in common.

We have seen that the "Ayurveda Sangraha" advertises a so-called specific for malaria called "Panchatikta Batika"; the "Ayurveda Prochar" has one also called "Rishabhak Batika" in both cases the effects of these drugs are compared with those of quinine in parallel columns: in each case the wording is exactly the same and the same wonderful results are claimed for each of these Ayurvedic drugs, while every effort is made to discredit quinine and to persuade the readers that it does more harm than good.

Considering the universally acknowledged specificity of quinine, and the beneficent efforts of government to

bring it within the reach of all, this action on the part of these quacks appears to us to be almost criminal.

In addition to the "Rishabhak Batika" we find "Bhunnibadi Kashaya" which is also represented as a safe and infallible remedy for malarious fevers of all kinds, with or without enlarged spleen and liver."

Both these firms advertise a compound to which they give the name "Makaradhwaaja," one says it was a gift from the "great god Shiva" the other that "it was probably discovered in course of the search for the Elixir of Life."

Of course it cures everything, we read that "the marked and undoubted benefit derived from its use in *all* (sic) diseases, is not only extremely astonishing but highly mysterious."

When a remedy cures every disease, it is naturally somewhat invidious to draw fine distinctions in describing its effects, but it is certainly a remarkable thing that this remedy seems to have different results in the hands of these two quacks. No. 1. says it cures all sorts of fevers, allays anorexia, dispels all sorts of neuralgic pains, removes every kind of disorders of the respiratory organs, digestive function, etc. No. 11. says it "may be specially recommended in general and nervous debility, a general break-up of the constitution, chronic and other malarial fevers, cough, loss of memory and other intellectual faculties," gonorrhoea, gleet, spermatorrhoea, skin diseases, female complaints, etc. etc., for more complaints than we have space for.

Below we have the following testimonial which, if genuine, we can hardly imagine was meant for public circulation.

SHAIKH JAMIRUDDIN, Vaccinator, from Rajarampur, Raniganj (*Dinajpur*) writes:—"During the nights, I was an awful victim to *night pollutions*. Your *Superior and Genuine Makaradhwaaja*, produced a very salutary effect and at once stopped those nocturnal seminal involuntary discharges."

It is perfectly evident from their catalogues that these quacks find it particularly advantageous to their illicit trade, to thrust under the eyes of the public, all sorts of supposed remedies for nervous diseases, female complaints, impotence, sexual disorders, etc. All such are freely advertised with plausible and artful suggestiveness.

The influence exerted by such advertisements is an immoral one, and it is impossible to exaggerate the baneful and degrading effects that the perusal of such literature must have upon the minds of many of its younger and more ignorant readers.

In the interests of morality and public health we think it is high time that some steps should be taken to check the unbridled license displayed in this style of advertisements.

In the catalogue before us we have the following *Brihat Chhagaladya Ghrita*, "extremely useful in" " " " general debility arising from despair, hopeless love, excesses and abuses " " " It is the finest aphrodisiac known."

Tala-Kalyana Ghrita.—"Is an aphrodisiac " " " It is very useful to females that are barren " " " It capacitates barren women for conception " " " If taken by males it acts as an aphrodisiac."

Chyavanaprasa for "gonorrhoea, spermatorrhoea and all other enervating diseases."

Sita-Kalyana Ghrita.—"It is very useful for all sorts of complaints of females regarding menstrual flow, * * specially indicated in leucorrhoea."

Himsagra Tala "is a boon to persons suffering from impotency." It is amusing to read that, "It relieves severe aching and cutting pains occasioned by a fall from a horse, camel, or elephant or any other high place." Surely the ingenuity of quackery cannot go further than this specific for a fall from a camel!

Maha Kameswara Modaka.—"It has the greatest aphrodisiac action and is used in Impotency with satisfactory results."

Ashwa-Gandha Ghrita.—"It is a very powerful remedy" * * for persons suffering from spermatorrhoea. It is so very potent in its action that it is said to rejuvenate (sic) old and infirm persons and to remove sterility. As a *nervine tonic* it is unrivalled * * can be safely used by children."

Madanananda Modaka.—"Is highly potent in curing Impotency. It is one of the best aphrodisiacs extant * * also used in spermatorrhoea."

Kumara-Kulpa-Druma.—"Excellent cure for sterility * * very useful to females and * remarkable and useful to those who do not menstruate or have not menstruated at all * * renders women capable of conceiving."

Amrita-Prasha Ghrita.—"The most powerful remedy for curing Impotency and for restraining seminal wastes, * * bestows on the patient eternal youth, so to speak, * * also cures all sorts of gonorrhoea."

And so the list goes on for another three pages until one is inclined to think that half the natives of Bengal are suffering from impotency, spermatorrhoea, sterility or gonorrhoea and that the chief necessity of their life lies in an aphrodisiac. We cannot however find space for any more of this disgusting rubbish.

As to the prices charged, we can only say that they are as exaggerated as the promises. For one tola (one rupee weight) of one of their remedies, these swindlers have the brazen faced impudence to charge Rs. 80.

As a supreme effort in therapeutics we may allude to "*Saraswatarista*" "*restorer of memory and voice*." This wonderful compound we are told "*sharpens the intellect enabling men to follow the most abstruse reasoning, and invigorates the mind so that long and deep thinking, prolonged studies and night-keeping (sic) do not strain or tire the system*." In the following sentence the advertiser appears to have been indulging his satirical vein, he says, "*The medicine is really an inestimable boon to Students, Singers, Actors, Orators, Lawyers, Stammerers and others whose power of articulation is defective*" surely this is rather hard on the Orators and Lawyers?

There is no getting to the end of the magical effects attributed to some of these drugs, so that we are not surprised to find that the above in addition to all its other virtues, is a cure for gonorrhoea as the following testimonial plainly shows.

BABU AKHOY KUMAR CHATTERJI, of Salap, District Pabna, writes:—"The *Chronic Gonorrhoea and Gleet* from which I have been suffering, has all but disappeared by the use of three bottles of your *Saraswatarista*."

It remains for us to bring to notice the medical men whose names are to be found in this quack pamphlet as giving testimonials to the authors. They are as follows.

Guru Gobinda Sen, L.M.S., Late House Surgeon of the Calcutta Mayo Hospital.

Adyanath Bose, L.M.S., Bhowanipore.

Ganga Dhar Roy, L.M.S., 24-Pergannaha.

Dr. Kali Prosonna Mukhopadhyaya, Medical Practitioner from Jalpaiguri. This gentleman says "I have given up practising as a doctor since I had the good fortune of noticing the wonderful effects of your medicines."

If he is the gentleman who appears under nearly the same name in the Calcutta Calender, the university might take notice of this naive admission of incompetence.

Dr. N. Banerjee, L.R.C.P., M.B.O.S., (London).

Dr. D. N. Chatterjee, M.B., C.M., (Edinburgh) Calcutta.

Dr. U. Gupta, M.D., (Edinburgh and Philadelphia).

Dr. R. G. Kar, L.R.C.P., (Edinburgh) Calcutta.

Dr. J. N. Mitra, M.R.C.P., (London) Calcutta.

Dr. Subhada Prasad Mukherjee, Birblum.

Babu Sashi Bhushan Ghose, Medical Practitioner, Chandpala, Barda, (24 Perga.)

Dr. H. W. Mitnish, M.B.O.S., London and Late Civil Surgeon in the Punjab

Dr. Udaya Chand Dutta, Civil Medical Officer, from Serampore.

A distinguished lady doctor from Pataldanga.

Dr. Nilmoni Das, Charitable Dispensary, Chirawar.

Dr. Bipin Behari Mitra of Jagdal, District Dinajpur.

Dr. Chundra Kanta Chuckerburty, Kanain Hospital, Cachar.

Dr. Sarat Chandra Sen, District Mymensing.

Dr. Ananda Chandra Gupta.

We give the above names as they appear in the quack catalogue. To the title of Doctor, none of them have any claim while guilty of such conduct.

Some of them are easily traced, and it is to be hoped that their universities will see their way to impress upon them the infamy of their conduct from a professional point of view.

Some are evidently not qualified practitioners at all, and others it is difficult to trace, owing to the want of that proper system of registration, the absence of which the Secretary of State for India so highly approves.

The necessity for discipline in the medical profession is so obvious, that it is extraordinary the authorities are so loath to recognise it, it is a very different case in the legal profession.

It is hardly necessary to allude to the revelations that have so recently occupied the attention of the English press, to point the moral.

The most severe disciplinary measures should be at hand to be put into force against qualified practitioners who league themselves with quackery.

Medical Education in India is indeed in a bad way when the highest authorities set their faces against the introduction of such measures, and when the universities see their diplomates prostituting their calling in this disgraceful manner.

MAJOR-GENERAL H. R. MORGAN ON THE TREATMENT AND PROPHYLAXIS OF PLAGUE.

We have received a copy of what we must call a very remarkable communication, addressed by Major-General H. R. MORGAN to the Resident of Mysore on the subject of "Plague Inoculation etc."

The object of the communication is to suggest an alternative to HAFKINE'S inoculation method in the prophylaxis of plague, which may be employed in cases where there is an objection to the latter.

As General MORGAN says, "It occurs to me that perhaps their scruples might be overcome, if we were to rely upon the veneration for the cow professed by all Hindoos, and they might be induced to try the protective treatment, if it could be introduced into the system in cow's milk."

The ideas upon which the new protective treatment are based will be gathered from the following brief account of experiments which General MORGAN gives, the treatment by the way is said to be curative as well as protective.

"Record of General H. R. MORGAN'S serum experiments."

"RINDERPEST IN 1890."

2. In 1890, out of a herd of 40 cattle, I lost 25 head, (13 cows, 12 calves), from cattle plague, which murrain was then raging in the district, running its fatal course in five days. The usual treatment having failed, and six other beasts being affected, I heard that a raw preparation of a diseased animal, its flesh macerated in water at a temperature of about 65°F. was a certain cure, administered internally, so I resolved to try it. I took the flesh of beasts which had been dead not more than 24 hours, (the fresher the better), cutting it from the hind legs where it seemed quite fresh, made the broth raw, and gave it to these six animals, when only one died, a full-blooded Aden bull, to whom it was given too late."

"There were five other animals in the herd which up to this time had not been affected by this rinderpest, so the broth was given to them as a prophylactic, and none of them took this plague."

"Some milkmen in Ootacamund were advised to try this remedy. They did so in 12 herds and saved their animals, which till then had been dying daily."

"In none of the animals, sick or well, treated with this raw broth, was there the slightest constitutional disturbance observed."

The dose of the strained raw meat extract was one pint twice a day to grown animals and half pint to calves.

We need scarcely remark that the terms "*Serum experiments*" and "*Serum method of treatment*" are complete misnomers in the connection, while the expression "*raw broth*" is merely a contradiction of terms.

What was used was simply a raw meat extract.

"CHICKEN CHOLERA IN 1891."

"In 1891 my poultry were attacked by chicken cholera, a meat extract, as before described, was made from the bodies of two fowls found dead in the morning, only the flesh being used, before signs of decomposition appeared. Result, "only two died out of 85, i.e., none at all after the use of the serum treatment" (sic).

"The birds which seemed unable to pick up food were considered ailing from the disease of which the two others had died, so they were first treated with the raw

broth, (sic), which was poured down their throats, a tea-spoonful at a time, several times a day."

"In the evening the invalids were able to take a little warm soft mash of boiled rice. The birds which were unaffected, had some of the raw broth, (sic), mixed with their usual food, and the disease did not spread."

FOOT-AND-MOUTH DISEASE, 1898.

"In September 1898, foot-and-mouth disease appeared at Salatha in my herd of 60 cattle, in common with those of surrounding villages; 7 were attacked, of which 1 cow and 3 calves died straight off. It must here be noted that foot-and-mouth disease is most fatal to English cattle and all calves.

"The usual treatment having failed to check the course of the disease, the following experiment was tried.

"A country cow, three days after recovery from the attack, was milked twice a day, giving 3 pints of milk in the morning, and 4 pints in the evening.

"An English bull in the early stage of the disease (1st or 2nd day) was so ill that he could not eat grass; so this cow's milk was given to him in a warm, soft, bran mash, one pint of milk in the morning, and one pint in the evening when the disease at once diminished in severity, inflammation subsiding and fever abating so rapidly, that the attack ran its course in half the usual time, (i.e., in 4 days, instead of 8 days), and on the 5th day he grazed spontaneously on the hill side. The whole of his mouth was raw, so it was considered dangerous to give him serum broth made from the flesh of the dead cattle, for fear he might get blood-poisoning by having this fluid applied to the raw surface of his sore mouth, so the milk of the convalescent cow was tried instead, and it did no harm, but seemed to have really a curative effect, without any constitutional disturbance.

"The rest of this cow's milk, 5 pints, was divided among six calves, twice a day, when they also improved at once, and were able to suck as usual. Both the bull and the calves had this treatment for only one day. On their convalescence this cow's milk, given in bran mash, was divided among 15 other cattle which became affected, (7 cows, 8 calves,) all of which quickly recovered, it being given to them as soon as they were found to be attacked.

"The rest of the herd were separated from the sick ones and the disease did not spread among them. The milk of this cow was given to them as a prophylactic."

The General's theory is that an antitoxin is ingested which has a curative and prophylactic effect, and makes suggestions for the application of his method to plague, briefly as follows.

A rabbit is to be inoculated with plague serum as soon as it has died, a raw meat extract (raw broth) is to be made. This extract is to be given to healthy rabbits to see if it gives them plague, also to plague-stricken rabbits to see if it cures them. "If they do recover from plague" he says "it will show that their serum has antitoxin in it" a rather rash conclusion.

Then the extract is to be given to a cow and the effect of its milk on plague stricken rabbits noted.

Such is a fairly full account of General MORGAN'S experiments and somewhat naive suggestions which we do not fancy our readers will be inclined to take too seriously; on the other hand his *bonafides* is undoubted, and it would be unfair to altogether laugh him out of court.

We do not think that the Bacteriologists need feel any pangs of jealousy at the invasion of their domain by an outsider, it is only too evident that General MORGAN is too ignorant of all that pertains to the subject on which he has let himself loose, to excite any feelings beyond those of astonishment and perhaps amusement.

Always supposing the diagnosis to have been correct, it is within the bounds of possibility that his meat extract was swarming with the special micro-organisms and their products, of rinderpest and chicken cholera, though the muscular tissue is not usually held to be their place of selection.

In such a case his extract should have proved itself a fertile source of infection, that it did not, but on the contrary appeared to have curative effects, may perhaps be taken as an addition to our knowledge of the therapeutic effects of meat juices.

Of a totally different character are the immunising and curative effects attributed by him to the milk of a cow recovered from foot and mouth disease. If the serum of an animal that has got well from an infectious disease possesses these properties, why not the milk? The argument is plausible enough, though it of course by no means follows that because the serum contains an antitoxin the milk does also. All things being considered however, the result put down to the milk treatment are altogether too wonderful to be accepted; and while General MORGAN's experiments may be taken as suggestive, it must be clear to any one acquainted in the smallest degree with bacteriology that they prove absolutely nothing.

The few scraps of medical literature, culled from various sources which General MORGAN ends up with as bearing upon, and giving some support to his theories, are irrelevant to an extent which is amazing and evidently quite beyond the grasp of the author. The last paragraph states that Veterinary Surgeon EDWARDS has cured 23 cases of rinderpest out of 25 seizures by means of raw meat extract made from the flesh of animals that has died from the disease.

General MORGAN has kindly contributed a paper on the above subject which appeared in our last issue and to which we may refer the reader for fuller details.

—:—

THE HARD CASE OF THE PRIVATE PRACTITIONER IN INDIA.

We have over and over again inveighed in these columns against the close condition of medical practice in India, and the frightful and most unjust extent to which the private practitioner is handicapped. Competition which does good in all branches of work and commerce, is not welcomed in medical practice in India, and the man who embarks upon it, has a hard and bitter fight before him, which too often appears to lead to no road except that of ruin and despair.

Officialism is rampant everywhere, the state paid doctor is all powerful, he is in possession and however unequal to the work there is to be done, he resents the presence of an unofficial confrere, who is looked upon as an intruder. The Civil Surgeons' domain is a close borough, and all is official favour, selfishness, and the Indian Medical Service.

We have had brought to our notice recently a particularly deserving case, which has obtained our utmost sympathy, as we are sure it will, that of our readers.

We refer to the case of HENRY D. McCULLOCH, M.B., M.S., L.M., who on the 12th July 1897, opened by private enterprise, an Eye and Ear Infirmary in Delhi.

This Institution was opened, and his half yearly report which is now before us, says, "with the treble object of affording charitable relief to those of the indigent poor afflicted with blindness, and diseases of the eyes leading thereto, and diseases affecting hearing, as an aid to ophthalmic practice and increase of experience to be gained in a very wide field of surgical knowledge as well as an aid to private practice."

That there is room for an institution of the kind in Delhi there can be not little doubt.

Delhi has a population of 200,000 and yet in ten months there were only 34 operations performed for the extraction of the lens for cataract. On the other hand in Amritsar, with a population of 120,000 there were 775 extraction operations performed in 11 months, while in the Mayo Hospital, Lahore, there were 827 during the year.

There is no special Government Eye Hospital in Delhi, and the above figures shew plainly enough, that the facilities presented to the public for the treatment of eye diseases are not nearly sufficient. This being so, Dr. McCULLOCH's venture was amply justified, and it is equally obvious that he was trespassing upon no one's domain, but striking out a distinct line for himself, and one which, if supported properly, would result in enormous benefits to the general public.

We regret to learn that this institution has not met with any adequate support either from Government or from wealthy private individuals.

The total expenditure for the six months ending 31st December 1897, was Rs. 2,218, the total income was Rs. 99. The difference has to be met by Dr. McCULLOCH who, we regret to say, is by no means in a position to thus lavishly give both his time, skilled ability, and money, without reaping any return.

By all the leading civil officials, his work has been tacitly ignored, and in India when official patronage is withheld, we regret to observe, that wealthy individuals are very slow to come forward.

The sad result is, that here in their very midst in the once proud capital of the Moguls, a work, a charity, which should appeal their tenderest sympathies is ignored, passed over and left to the despairing efforts of one private individual.

Should this state of things continue we are sorry to learn that Dr. McCULLOCH's charitable venture must soon come to an untimely and unfortunate end.

From amongst the officials who have passed by on the other side, we must except Colonel R. A. P. RENNICK, then commanding at Delhi, who not only visited Dr. McCULLOCH's Infirmary with his staff, but also unsolicited, gave the founder a testimonial expressing his sense of the good work that was being done in the institution. "The Public," Colonel RENNICK says "hardly knows the really humane and good Christian work Dr. McCULLOCH is engaged on. The desperate and hopeless cases I have seen under treatment which promised every success, gave me

ample evidence of his earnestness and devotion to the treatment of the blind which ought to secure for him every support and encouragement." To the testimonial was added a valuable donation of Rs. 50.

We ought perhaps to mention some particulars concerning the personality of Dr. M'CULLOCH who is a Scotchman holding the degrees of M. B. and M. S. of Edinburgh and the L. M. of the Rotunda of Dublin. We have before us a number of his testimonials all of which speak of his early career in terms of praise and appreciation.

From a testimonial signed by Lieutenant-Colonel D. W. K. BARR, late Resident in Kashmir and Agent to the Governor-General, Central India, we learn that Dr. M'CULLOCH was employed as a Medical Officer in the Kashmir State for 10 years. "I can certify" Colonel BARR says "that Dr. M'CULLOCH is energetic, active and obliging, and that he is well suited to any medical appointment requiring a man with these qualifications."

Another testimonial is signed by Colonel NEVILLE CHAMBERLAIN, Military Secretary, Kashmir State, praising the good work done by Dr. M'CULLOCH in the autumn of 1891, in connection with the transport of troops and stores to Gilgit. "As regards your work at Astor after your arrival there" he says "in looking after a hospital full of men suffering from frost-bite and in acting as Transport Officer by forwarding stores to Gilgit, I believe the results were eminently creditable to you."

In connection with this service we learn from another testimonial signed by Captain W. R. YIELDING, Assistant Commissary-General, that Dr. M'CULLOCH obtained the thanks of Government.

"I am directed to state" Captain YIELDING says, "that the Government of India consider the reports valuable and interesting, and I am to request that their acknowledgement may be conveyed to Dr. M'CULLOCH."

All these are testimonials that any man might be proud of. Yet of what avail are they in a country like India?

And now a word on the subject of Delhi and its medical appointments. There are few if any Civil Surgeoncies in India where the appointments are so numerous.

We may enumerate the following:—Medical officer of the Civil Hospital,—The Lunatic Asylum,—The Central Jail,—Police Surgeon, The E. I. Railway,—The N.-W. Railway,—The S. P. Railway,—The R. M. Railway,—The D. N. Railway, all of which meet in Delhi. Ex. Officio Health Officer, the care of the officials of the E. J. Canals and of the W. J. canals,—the Schools,—the Cambridge Missionaries,—and finally the Mills and Factories over which a sphere of influence is exercised.

This gives some idea of the work the Civil Surgeon of Delhi is supposed to do. Of course it is utterly impossible for one man to properly perform even a portion of this work. The mantle of the Civil Surgeon spreads however and covers some of his subordinates.

In this way we find his House Surgeon, an Assistant Surgeon, in charge of one of the Mills and in addition running a private practice in the city. Another Assistant Surgeon is styled the Assistant Civil Surgeon, he is house Surgeon at the Police Lines Hospital and Civil Dispensary, he also has a private practice in the City.

While, what is worst, we have the post of Executive Health Officer occupied by a native who runs a chemist's shop, without even the qualification of a Hospital Assistant.

That the Civil Surgeon should acquiesce in these irregular practices and connive at some of his unqualified assistants conducting private practice on their own account, comes perilously near to what is generally known as "covering," and it is perfectly certain that such things could not be done in England.

We have gone into this case pretty fully as it is a fair representation of what the unofficial private practitioner has to encounter in India.

We trust our having drawn attention to it may do some good, and that Dr. M'CULLOCH may not be driven for want of funds, into closing an enterprise so beneficial to the poor of Delhi.

THE EIGHTEENTH MEETING OF THE COUNCIL OF THE INDIAN MEDICAL ASSOCIATION.

IN accordance with Notices issued by command of the President, the Eighteenth Meeting of the Council of the Indian Medical Association was held at its Office, 50, Park Street, Calcutta, on Monday, the 28th November 1898, at 6 P.M.

Present.—Dr. LAL MADHUB MOOKERJEE, Rai Bahadur, (President, in the Chair) Drs. H. W. JONES, RAJHAL DASS GHOSH and J. R. WALLACE.

Business.—(1). The Notice calling the Meeting having been read, the Minutes of the last Meeting of the Council, were read and confirmed.

(2). The Secretary presented the names of 11 new members who had applied for admission to the Association. They were duly elected.

(3). THE INDIAN MEDICAL ASSOCIATION PROVIDENT FUND.—The Secretary reported that three members of the Fund had died, and their nominees had sent in their claims for adjustment. *Resolved*, that the said claims be paid in accordance with the Rules of the Fund, to the extent of one rupee for every member of the Fund, as represented by fully paid subscriptions.

(4). THE NEW CALCUTTA MUNICIPAL BILL.—The Secretary laid upon the table letters from Government acknowledging the Council's representation on this subject, and intimating that its suggestions would be duly considered.

(5). MEDICAL, PROFESSORIAL AND HOSPITAL APPOINTMENTS IN INDIA.—The Secretary laid upon the table letters received from the Supreme and Provincial Governments in connection with the Council's representation on this subject. *Resolved*, that a copy of the Council's letter to Government be forwarded to the General Medical Council of Great Britain and to the Secretary of State for India.

(6). THE IMPORTATION OF DOCTORS AND NURSES FROM ENGLAND FOR PLAQUE DUTY IN INDIA.—The Secretary informed the Council that an important communication had been received from the Supreme Government concerning this matter. It was considered desirable that the said letter be published as follows:—

No. 1561. FROM A. H. L. FRANKER, ESQ., C.S.I.,

Officiating Secretary to the Government of India.
TO THE SECRETARY, INDIAN MEDICAL ASSOCIATION.

Home Department (Medical)—Simla, the 4th Nov. 1898
SIR,

I am directed to acknowledge the receipt of your letter, dated the 12th October, submitting a copy of a Resolution passed at a meeting of the Council of the Indian Medical

Association, on the subject of the importation from England of doctors and nurses for plague duty in India.

2. In reply I am to say that the Governor-General in Council entirely agrees with the Council of the Association, that it is desirable to employ local doctors and nurses, and His Excellency in Council has been throughout very anxious to use local medical and nursing talent to the fullest extent to which they were available. Every effort has been made by the Government of India and Local Governments to secure the services of private medical practitioners and medical officers who have retired from the service of Government, but who are not disqualified physically or by reason of their age for further employment. Of 125 persons who were offered temporary employment on account of plague, 68 refused such employment or could not be found, the services of 41 were engaged by the Director-General of the Indian Medical Service, 10 were engaged by or referred to Local Governments, and only 6 were rejected as unsuitable. These figures do not include a number of doctors and nurses employed by Local Governments without reference to the Director-General of the Indian Medical Service. The list of applicants maintained by the Director-General of the Indian Medical Service, contains at present the names of only 2 suitable doctors and 1 nurse. These facts indicate that the Government of India have utilized as far as possible the available local talent, and have had recourse to England only because sufficient doctors and nurses cannot be procured in India.

3. I am to add that the claims of any local candidates whose antecedents and qualifications are satisfactory will continue to be favourably considered by the Government of India.

I have the honour to be,

Sir,

Your Most Obedient Servant,

A. H. L. FRASER, *Offg. Secy. to the Govt. of India.*

Resolved, that the Secretary do address the Government of India on the following points:—(a) information as to what means were employed by the Director-General, I.M.S. to obtain the services of qualified local medical men and nurses before application was made to London for English doctors and nurses, (b) whether the services of local doctors and nurses were sought for by means of advertisements in the medical and lay papers of the country, (c) whether the Director-General, I.M.S., would kindly provide the Council with a list of the local doctors who were offered work in connection with plague duties, (d) whether the Government will kindly state the qualifications required of candidates for plague duty with special reference to the question of the acceptance by Government of men holding Indian degrees and diplomas, (e) whether, having regard to the fact that the Council possesses a complete directory of qualified medical men, and is in touch with them through the *Indian Medical Record*, the organ of the Indian Medical Association, the Government of India will be pleased to make known its future requirements for medical men, and if so, the Council would gladly undertake the duty of forwarding the names of medical men whose qualifications the Government is prepared to accept, (f) that with regard to the employment of properly qualified local nurses, the Council would have much pleasure in co-operating with the Council of the Imperial Anglo-Indian Association, with a view to providing, for Government employment, the services of as many locally trained nurses as may be required for any emergency that arises.

(7). **INDEPENDENT MEDICAL COLLEGES IN INDIA.**—The Secretary raised a discussion on this subject. He referred to two Independent Medical Schools in Calcutta, one of which, though well equipped in many respects, was greatly handicapped in the matter of clinical instruction in meeting the requirements of its large lists of students. At present the students of the Calcutta Medical School were compelled to attend the Mayo Native Hospital, where, though the medical superintendent very kindly allowed them the fullest opportunities for clinical study which his hospital afforded, still none of his staff held the position of clinical teachers. Another difficulty exists in the fact that the Mayo Hospital is about 2 miles distant from the Calcutta Medical School. It is clearly realised that this institution, which is deservedly very popular, and which has received the countenance and patronage of three Lieutenant-Governors of Bengal, has not only justified its existence, but has a very rightful claim on the sympathy and support of the Bengal Government. That it is doing useful public work and meeting a long felt want, is proved by the success and largely utilised talent of its alumni, as also by its roll of students which now numbers 421. The School does not seek financial aid from Government, but it is now felt that with its acknowledged usefulness in its special field of operations, in providing the poor in rural districts in Bengal with fairly well trained medical attendants, the Council should approach Government on behalf of the school with a request that its students, provided they fulfil all the necessary requirements of the regular students of the Campbell Hospital Medical School in the matter of preliminary educational examination, attendance at lectures, dissections, chemical laboratory work etc., be permitted to attend the Scaldah Hospital wards with their teachers, who should be appointed honorary medical officers to the hospital. A certain number of patients in the wards should be allotted to each honorary teacher for the purpose of clinically instructing his students, provided that such attendance on the patients of the hospital by the medical and surgical teachers of the Calcutta Medical School, be done gratuitously and without any extra cost to the Government or the Hospital. That such a boon, while very materially assisting the efficient training of this class of students, would not only benefit them, but prove a blessing to the very necessitous portion of the native population among whom such medical men have ultimately to labor, inasmuch as they would thus be more intelligently and effectively trained and thoroughly qualified to treat medical and surgical diseases. It was considered desirable also in view of the fact that the other independent medical school referred to, is badly equipped, insufficiently officered and very poorly attended, it should amalgamate its resources with the Calcutta Medical School, so that by united effort, the local medical profession, represented in one section of its well educated and energetic Bengalee practitioners of Calcutta, might have an opportunity of opening a promising avenue for those of their number, whose aspirations and talents direct them into the field of medical teaching and medical research.

(8). **A TECHNICAL SCHOOL FOR SANITARY SCIENCE AND A DEGREE IN PUBLIC HEALTH.**—The Secretary raised a discussion on this subject, and suggested that the Bengal Government be asked to establish a school for training Sanitary Inspectors and for the purpose of preparing the

medical students of the Calcutta University and other local medical schools for a degree or diploma in Public Health, where practical hygiene and sanitary engineering would be suitably taught. The Council approved of this valuable suggestion and instructed the Secretary to approach the Bengal Government on the subject by letter.

(9). Certain accounts and bills having been passed for payment, the meeting closed with a vote of thanks to the chair.

THE SURGERY OF PELVIC INFLAMMATION.

DR. CHARLES of Cullingworth, who opened the discussion on this subject at the B. M. A. meeting in Edinburgh, divided pelvic inflammation into two main divisions (1). When the primary and predominant lesion is in the connective tissue area of the pelvis (cellulitis). (2). When the primary lesion is intraperitoneal (pelvic peritonitis).

In the first case, when suppuration does not take place there is no indication for surgical interference.

When however pus forms it should be let out. The operation should always be performed without opening the peritoneal cavity, in the majority of cases the abscess points externally above Poupart's ligament, where the incision should be made.

Sometimes the suppuration occurs behind the posterior parietal layer of the pelvic peritoneum, the abscess is too deeply situated to point, and its existence is only a matter of inference, the indication for operation is not so clear and the operation is complicated. The incision should be as for tying the external iliac artery followed by careful dissection beneath the uplifted peritoneum.

Abscesses situated between the layers of the broad ligament at its upper part are very rare, if they ever exist. Cases described may have been cases of pyosalpinx or suppurating ovary in which the broad ligament has been drawn over the inflamed organs in the form of a hood concealing them from view.

The indications for operation are as a rule less clear in cases of pelvic peritonitis. Still it may be said that operative interference is necessary in the following circumstances, when after the subsidence of the acute symptoms in a case of pelvic peritonitis due to tubal inflammation, a bimanual examination reveals the presence of a swelling on the posterior fossa of the pelvis on one or both sides, which exceeds in size a simply thickened Fallopian tube or a slightly oedematous ovary, and if such a swelling is found to be increasing in size in spite of rest in bed and the local application of warmth, it is almost certain that pus is present.

Again, if during an attack of acute inflammation of the uterine appendages a tense, globular, cystic swelling be formed in the pouch of Douglas, bulging downwards into the vagina and backwards into the rectum, the probabilities are strong that the swelling is an intraperitoneal abscess. Even if the contents of the distended pouch prove to be serous and not purulent, the relief of tension is necessary, so that here again the need for surgical interference is imperative.

Thirdly the outbreak of recurrent attacks of pelvic peritonitis in a patient who has had an acute salpingitis and in whom there has remained a quiescent but obvious swelling on the posterior part of the pelvis. Such attacks

are very suggestive of a collection of pus and the need for operation.

Finally operation becomes urgent when there are symptoms of general septic infection with history of pelvic inflammation and the presence of a localised swelling above the vaginal roof. Such cases frequently prove to be what is termed tubo-ovarian abscess, that is to say where a communication has been opened by ulceration between a suppurating Fallopian tube and a cyst in the adjacent and adherent ovary.

Non-suppurative pelvic inflammation tends to get well without operation, there are exceptions however where operative measures are called for, as in cystic disease of the ovary and hydrosalpinx.

Again other circumstances may justify an operation as when the woman belongs to the working class, and is willing to take the risk in order to be cured quickly.

Regarding the choice of time for the operation it should if possible not be undertaken in the acute stage but as soon after as possible.

M. DOYEN (Paris). Peritubal collections of pus have their seat (1) in the subperitoneal connective tissues (iliac abscesses), (2) in the peritoneal cavity itself (ovariitis, salpingitis, and peritoneal suppurating cysts).

Purulent collections low down in the broad ligament may be opened by a lateral colpotomy by plunging into the inflamed ligament a long forceps, and emptying the abscesses that lie low down close to the uterine artery.

Suppuration of the annexa develops mostly in the tubes themselves, there are three methods of operating (1) Simple incision of the purulent pouch by posterior colpotomy (2) vaginal castration; (3) laparotomy.

Any exclusive method should be rejected. Laparotomy should not be used when the septic focus can be reached by vaginal incision, and vaginal hysterectomy is contra-indicated when the purulent pouch reaches above the brim.

RULES FOR CHOICE OF OPERATION.

Extra peritoneal suppuration—(a) Abscess of broad ligament.—(1) By classical iliac incision. (b) Abscess of the inferior portion of the broad ligament; lateral colpotomy.

INTRAPERITONEAL SUPPURATION.

(a) The inflammatory mass remains intrapelvic, and does not reach above the brim: vaginal operation. (b) The suppurating tumours pass the brim of the pelvis, and reach the level of the umbilicus: laparotomy.

By each one of the above methods, vaginal or abdominal, three distinct operations may be performed: (1) Simple incision of the purulent focus; (2) ablation of the annexa, leaving the uterus; (3) total castration.

Concerning the vaginal method, in young women in whom castration would be an unnecessary mutilation, I content myself with free incision and tamponing the cavity; such cases can subsequently bear children.

If the annexa on one side are recognised to be diseased they are removed by colpotomy, the annexa on the other side and the uterus being left intact, if both sides are diseased (which can only be discovered during the operation) both are removed with the uterus.

Regarding laparotomy, certain encysted purulent collections limited by peritoneal adhesions can be cured by simple incision.

When pus is contained in the tubes they must be completely extirpated.

Total Abdominal Castration. Is it rational to practice ablation of the uterus in every case of bilateral suppuration of the annexa? Assuredly not. When the uterus is healthy and not painful, and when its ablation in women much reduced in strength, may lead to an aggravation of their state it should be left. Its ablation is also useless in tuberculous salpingitis, when it is healthy.

The vaginal method and laparotomy are not competing methods. Each has its own indications. M. JACOBS (Brussels) who has operated on 713 women for pelvic suppuration, considers that the vaginal method should be selected in old standing cases of pelvic suppuration with fistula, adhesions and peri-uterine abscess.

The abdominal route is the best in relatively recent cases in which there is no evidence that surrounding organs are seriously involved, following this rule M. JACOBS has had only 8 deaths out of 432 vaginal coeliotomies and 3 deaths out of 98 laparotomies. M. LANDAU (Berlin) said that he had performed 58 vaginal coeliotomies in the course of three and a half years without losing a single case. Those patients who were operated on by vaginal coeliotomy for true,—not inflammatory,—tumours and for extra-uterine pregnancy were permanently cured. In patients with inflammatory conditions only 20 per cent. at best were cured.

M. MARTIN (Berlin) said, I lay great stress upon the history for much depends on whether there is a history of gonorrhoea or not. In gonorrhoeal cases an expectant treatment will often answer quite well, but in septic cases operation is almost always necessary, and is often required in the acute stage when high fever is present.

He remarked that the bacillus coli was a frequent cause of pelvic inflammation especially in quite young women which had not attracted sufficient attention. The first condition may be constipation, menstruation comes on, and marks the beginning of the pelvic trouble, within a few years definite swellings are found, then if operation be done, it is found that there are adhesions between the tubes and the intestines."

—:—

CAPTAIN THOMSON, I.M.S. ON THE CALCUTTA PLAGUE.

We have from the first openly expressed and maintained the opinion that the disease officially called plague in Calcutta was not true plague, and we were inclined to think that the course of events amply justified this view. We have from time to time set forth our ideas on the subject and we have given various reasons for our convictions.

Our readers are well acquainted with them, so that there is no reason to rehearse them again in this place, suffice it to say that they are unaltered and that far from seeing any reason to modify them, we hold them to be more justified than ever.

These remarks are called forth by a letter from Captain G. S. THOMSON, I.M.S., Civil Surgeon of Satara, which appears in our correspondence columns.

It is no doubt a difficult thing to diagnose plague in

Calcutta from such a distance, so that Captain THOMSON clearly labours under a great disadvantage, it is after all only natural that he should feel inclined to credit and support the official accounts, nor do we quarrel with him because his ideas happen to be opposed to ours.

Far from it, we only wish that he had something of a more convincing nature to communicate, and that he was able to clothe his ideas in language a little more lucid and a little freer from grammatical blunders.

We expect something better in these respects from the officers of a service, which is so fond of boasting of its superiority.

Captain THOMSON does us an injustice when he says that our opinion of the so-called plague was based "on the false, self-laid down, criteria, that it has become neither contagious or (sic) epidemic." The evidence brought forwards by us and upon which our opinion was founded, was by no means confined to these phenomena.

"Two facts" he then says "will, I feel sure correct your misunderstanding and enlighten your ignorance."

Where these two facts are we leave our readers to discover, for we have failed in our search, for after a long quotation above the name of MILROY he passes on to what he calls a "confirmatory fact," confirmatory that is of the other two and therefore a third fact.

This third fact is unfortunately also missing, but we are invited to seek it in "The Transactions of the Bombay Medical and Physical Society for March" where Captain THOMSON tells us "I elucidated and enunciated 'The want of Fresh Air Theory,' of plague."

We are sorry that we are not acquainted with Captain THOMSON's "Want of Fresh Air Theory" of plague, and that time prevents us exploring it for this buried fact.

His facts are therefore illusory and leave us but little better off than we were before.

Does it occur to him, when backing up certain individuals, that official reports are scarcely to be taken as expressions of personal opinion? It is not surprising to find subordinates colouring their views to harmonise with the prevailing Secretariat tint.

Again we may remark that the remarkable abstention from bacteriological research in the Calcutta disease was not without its special significance for us.

Captain THOMSON has a curious idea of pleasure, or possibly of the meaning of the word "unique" when he tells us that he "had the unique pleasure of acting as plague preceptor to Dr. BANNERMAN and DYSON." We hope they appreciate the compliment. He has, however, a very shady idea of the duties of the Sanitary Commissioner of Bengal, if he thinks, he spent his time going about diagnosing plague cases.

Captain THOMSON accounts for the so-called plague not spreading in Calcutta in the following way : "The Disease" (plague) he says, "is conditioned and is only infectious when there is want-of-fresh (sic) air ; (sic) due to deficiency of it, (!! We wonder to what else it could be due) filth or over-crowding."

To those who know Calcutta this will be strange reading. Distance certainly lends enchantment to the view, but that even from the distance of Satara, Calcutta should be held up as a sort of Sanitary paradise, where plague could not spread because there was no over-crowding and no filth, is almost incredible. Yet such is Captain THOMSON'S view ! Surely the Municipality has smelt a sweet smell (an unwanted luxury for it) of incense offered from afar.

Captain THOMSON has evidently a very erroneous idea of the size of Calcutta, when he says that "about half the people ran away from the city." We wonder what figures he relies upon, but he is altogether too illogically funny, when he ascribes their running away to the fact that they believed plague was due to fate. "They had" he says, "to bolt into the jungles and elsewhere."

The people who ran away, did so, not from fear of the plague, but from fear of the *plague regulations*. The fact of their believing that plague was due to fate, as Captain THOMSON puts it, was the very thing to keep them at home.

Captain THOMSON'S theory about plague apparently is that it is only infectious when there is a want of fresh air. We wonder how he explains the recent cases that occurred in Vienna on this theory.

The Vienna doctor who attended the first case undoubtedly caught it from his patient, the nurse's case was an equally well-marked one of infection. Yet they all occurred in a well-appointed Vienna hospital.

We will conclude with two of Captain THOMSON'S choice specimens of English, which we think, might very well be set for correction in a Calcutta University paper, "faithfully clinical type of disease," "its absolutely non-contagiousness."

FOURTH ANNUAL MEETING OF THE INDIAN MEDICAL ASSOCIATION.

The Fourth Annual Meeting of the Indian Medical Association will be held at the Office and Library of the Association, 50 Park Street, Calcutta, on Friday, 28rd December 1898, at 5 p.m. All members of the Association, and all other qualified medical men and women are cordially invited to attend.

JAMES R. WALLACE, M.D., F.R.C.S.,
Secretary, Indian Medical Association.

PUBLIC NOTICE.

INJUSTICE IN GENERAL.

1. **WANTED.**—Fair Trade in Medical Journalism. The Bengal Government subsidizes and supports a private medical journal, and thus misuses public money. Public protest has failed to stop this injustice. The *Indian Medical Record* has flourished for nine years without State support and has won the confidence of the medical profession. The other paper has struggled on for 25 years with the aid of public funds. Comparison of subscription lists will prove these facts. The Bengal Government is guilty of injustice in this matter, and it is hereby declared, that this **NOTICE** will continue to appear in this form and in this position until the Lieutenant-Governor of Bengal, puts an end to this disgraceful and iniquitous system of State subsidy to the paper complained of, which is owned by a private trading firm.

2. **WANTED.**—For the Medical College of Bengal in Calcutta, a fully qualified Surgeon and Teacher of Surgery, to occupy the position of Surgeon to the Calcutta Medical College Hospital and Professor of Surgery to the Calcutta Medical College. The aspirant should be a tried and experienced practical surgeon, well versed in all the lore of ancient and modern surgery, and be thoroughly capable of teaching a large class of students (who pay the Indian Government for their education) the following subjects:—General Science of Surgery, Surgical Anatomy, Surgical Pathology, Practical and Operative Surgery, and Clinical Surgery.

NOTE.—Certain candidates of the Indian Medical Service, even though they be unqualified, will be favourably received by the Chief Secretary to the Government of Bengal, but it is specially notified that all other applicants outside the service of Her Majesty's Government in Bengal or in India, must be fully qualified.

This **NOTICE** will stand unchanged until the Bengal Government removes the present incumbent of the chair of Professor of Surgery (Mr. R. D. Murray, M.B., who studied modern surgery in 1873, vide *Englishman*) and until justice is done by providing the students of the Calcutta Medical College with a proper Teacher of Surgery.

COMMENTS AND NEWS.

MEETING OF THE STRAITS SETTLEMENTS BRANCH OF THE INDIAN MEDICAL ASSOCIATION.

THE annual meeting of the Straits Settlements Branch, I M A was held on 17th August 1898, at the residence of Dr W R ANGUS.

The members present were Messrs. A B LEICESTER, (Chairman), W R. ANGUS (Member of Committee for Singapore) J A BEARDON, H J GIBBS, (Honorary Secretary), J V PESTANA.

The Chairman in opening the meeting said 'It is my pleasing duty to open to night the third session of our association. We have not been able yet to accomplish those aims to which reference was made in my address last year, and as I then said in dealing with matters affecting our personal condition we must exercise great discretion and bide our time.

It is very gratifying to note the interest taken by members in contributing notes on subjects interesting to the profession and particularly so to note the revival of spirit among, and the energy and interest shown by our Penang colleagues in this direction, as well as in another, that is, discussion of professional subjects. I hope to see Malacca following in their wake so that our combined efforts may in a greater degree merit the already obtained reputation for excellence in our Annual Reports from our parent association.

I would now call upon our worthy Honorary Secretary to read the report of the past session."

The Honorary Secretary then rose and addressed the meeting as follows —

"Mr Chairman and Gentlemen,

It affords me much pleasure on a second occasion to have to record another year of useful work on the part of the members of the Straits Settlements Branch of the Indian Medical Association and it is especially gratifying to see how ably Penang has come to the front in the interest manifested in the discussion of professional subjects. Malacca, much to my regret, however, still remains true to its tradition of being the "sleepy hollow."

Some of our members have, I think, just cause for complaint against the parent association in that though they have paid their subscriptions they are not furnished with the promised membership certificates. One member refuses to pay a single cent further towards the association if his certificate is not forthcoming very shortly, and I must say that I quite support him in his action. I have written on more than one occasion to the Indian Secretary on the matter, but so far my efforts have been fruitless to procure the necessary certificates. Eight Meetings have been held in Singapore and five in Penang. The average attendance in Singapore was five, while in Penang it is stated to have been 100."

The adoption of the discussion of professional subjects in addition to the reading of papers and notes has, I think, had a very good effect. One of the Penang members wrote to me stating that their weekly meetings were doing their members a great deal of good, and suggested that I should write to the Secretary at Calcutta and suggest to him that the Indian members do likewise. I must here congratulate Messrs J W W HOGAN and J F CARRIGY on passing their professional examination for promotion from the 1b 150 to the 1b 175 grade.

Two members Messrs D'VAS and BATEMAN were admitted, and Mr. BEARDON, who had returned from leave, was readmitted during the year.

I regret to have to report the loss of 2 members to the

Association, one Mr. GAWTHORNE by death, the other Mr. M. W LAPORTE by resignation. Mr. LAPORTE's resignation is greatly to be regretted, but as he attributed it to purely private grounds there was no help for it.

At the last annual meeting I likened the condition of this branch to the fretful stage of a teething infant, but now I am happy to be able to state that the infant branch is not only sturdy in its growth, but that it has cut all its temporary teeth.

The correspondence of the year chiefly consisted in the forwarding of the minutes of the meetings to the Indian Secretary for publication in the *Indian Medical Record*, the conveying of a vote of sympathy to the widow of the late Mr. GAWTHORNE and in two letters of your Secretary to a private practitioner taking him to task for an unjustifiable attack on a member of our Association which had the effect of casting a slur on the whole of us, and to a member of the British Medical Association who took the part of our members against the aforesaid private practitioner.

At our first meeting of the session under review held on the 13th November 1897, the chairman, Mr A B LEICESTER, read his inaugural address which included some remarks on general diagnosis. On Mr PESTANA's suggestion it was resolved that the subscription of members be raised from fifty cents to one dollar a month and that with the increased subscription so obtained, a copy of the *Lancet* be taken in for the benefit of the Singapore members. This has been done, and, to the undoubted benefit of those who read the paper.

Mr. GIBBS showed specimens of hæmin crystals and the method of preparing them.

Mr C J BATEMAN who had lately qualified as an assistant surgeon was admitted a member of the local branch.

On 13th December 1897, Penang notified that its members would hold weekly meetings to discuss professional subjects, and, on the 17th December the Indian Secretary forwarded several printed copies of our last Annual Report which had previously appeared in the *Indian Medical Record*, and which he was pleased to term "excellent" for circulation amongst the Straits members.

At the monthly meeting held on 17th December, Mr. LAPORTE's letter of resignation was considered and the Secretary was instructed to write to Mr LAPORTE and ask him to reconsider his resignation, and in the event of his declining to do so to kindly state the reasons for his taking such an extreme step. It was also resolved on the chairman's suggestion that every member of this Branch should provide himself with a fortnightly copy of the *Indian Medical Record* so as to support the parent association as well as show his loyalty towards it.

The following subjects were discussed: Dysentery, Abortion and Dislocations of the hip.

On the 24th December 1897 Mr. LAPORTE in reply to the Secretary, wrote declining to reconsider his resignation, and further stated that as his reasons for resigning the association were purely of a private nature, he considered the members had no right to ask to be informed of them. He also stated that he had severed his connection with the parent association.

At the meeting held on 15th February 1898, Mr. BEARDON attended as a visitor, and Mr. CARRIGY's query as to whether it was necessary for him to forward minutes of the meeting of the Penang members through the local Secretary for publication in the *Indian Medical Record*, was decided in the affirmative.

The Secretary was instructed to write for a copy of the *Indian Medical Directory*. Pleurisy, Post-partum hemorrhage and Fractures of the upper extremity were discussed.

On 16th March 1898, Mr. AMBA read his paper on the mal-praxis of native midwives in Singapore and the following subjects were discussed. Pregnancy and the diseases connected with it and the eruptive fevers. It was also resolved that Penang be asked to exchange its "Practitioner" with Singapore's *Lancet* after their respective members had done with these papers; and that the Malacca members be asked to contribute fifty cents each monthly towards defraying the cost of the *Lancet*. Malacca has failed to see the force of this argument.

On the 19th April 1898, Penang notified its willingness to exchange the above journals. Singapore has forwarded its *Lancet* but Penang's "Practitioner" has not been forthcoming. The following subjects were discussed, plague and cholera, normal labour, the puerperal state and its management and dislocations of the shoulder.

At the meeting held on 27th May 1898 Mr. RYLANDS of the Lahore medical service attended as a visitor; and Mr. REARDON's proposal that the meetings be held of an afternoon and once a week instead of at nights and monthly was negatived by the majority of the members present. Mr. GIBBS read his paper on "The microscope as an aid to diagnosis, the staining of bacteria and the preparation of nutritive media."

On the 4th June 1898 at the meeting of the Malaya Branch of the British Medical Association at which your Secretary was the guest of one of its members, a member of the above association tried, unjustly, to belittle the members of our association in the eyes of his colleagues and of the naval medical officers of H. M. S. "Hermione." This attack upon us was promptly resented by two other members of the British Medical Association, who ably supported us, and by your committee who, after fully investigating the matter, permitted your Secretary to write a letter to the offending member which utterly refuted his charge; and I have since heard, privately, that the member referred to extremely regrets his unwarranted attack upon us.

It is very pleasing to have to record the celebration of the silver wedding of our worthy Chairman Mr. A. B. LEXCHESTER on the 9th July 1898; on which occasion his colleagues presented him with a handsome silver tea service.

At the meeting held on 18th July 1898, phthisis, pneumonia, the urine in health and in disease and funis presentations were discussed and the date for the Annual meeting was fixed for the 17th August, 1898.

The professional subjects discussed by Penang during the year cover a fairly wide field, and shows the great interest Penang is now taking in the professional advancement of its members.

In conclusion I beg to express my thanks to one and all of you, and especially so to the chairman and the members of committee, for the kind consideration shown and the fullest confidence placed in me. Without this confidence I would have found it exceedingly difficult to have carried on the work of the Association to the satisfaction of its members. You will be presently asked to elect officers for the carrying on the work of our Association for the ensuing year, as to the selection of a Secretary, who of necessity, has to bear the brunt of the work, I would recommend the following words of the late Cardinal MANNING for your consideration. "To live is to change, and, to change often the nearest approach to perfection."

On the completion of the reading of the above report the members bearing office tendered their resignations, and the members were asked to vote for the election of officers for the ensuing year.

For the Chairmanship,—Mr. A. B. LEXCHESTER received 11

votes, Mr. W. B. ANGUS received 2 votes, Mr. LEXCHESTER was thereupon elected Chairman.

For the Secretary,—Mr. J. A. REARDON received 2 votes, M. H. F. GIBBS received 10 votes, Mr. A. HALE received 1 vote, Mr. GIBBS was elected Honorary Secretary.

For the member of Singapore Committee,—Mr. W. R. ANGUS received 5 votes, Mr. J. A. REARDON received 5 votes, as these members "tied" a re-ballot was asked for with the result that Mr. W. R. ANGUS received 3 votes, Mr. J. A. REARDON received 1 vote, Mr. ANGUS was therefore elected.

For the member of Penang Committee,—Mr. M. E. SIKWAN received 3 votes, Mr. C. V. NORRIS received 1 vote, Mr. J. F. CARNEGIE received 9 votes, Mr. CARNEGIE was elected.

For the member of Malacca Committee,—Mr. WRAY received 9 votes, Mr. G. M. RUPPA received 2 votes, Mr. WRAY was elected, neither Province Wellesly nor Malacca voted.

THE CAUSE OF AND SUSCEPTIBILITY TO DISEASE.

At the meeting of German Naturalists and Physicians at Dusseldorf, September 19th to 24th, 1898, HERR MARTINS ROETOCK discussing the above subject said that in reference to disease the causes assigned were usually wanting in logical definiteness. It was of the nature of a cause that it should always be followed by a certain effect. Bacteriology claimed to do away with the old uncertain connection between cause and effect. According to the new teaching every individual of a susceptible species fell ill with unfailing certainty every time that there was a previous infection with the particular pathogenic micro-organism. According to bacteriology microbes were the direct and only causes of diseases, it was of the nature of a necessity that they should produce diseases.

"These facts have been derived from experiments on animals, and the unprecedented importance attached to them, was due to their too hasty application to human pathology."

"If they are correct, every natural infection with a specific cause of disease in man, should be followed by the typical sickness."

"It has caused no little perplexity, that this conclusion so apparently self-evident on the ground of etiology has proved to be false."

RUMPF states that in 60 cases that he examined after the Hamburg Cholera epidemic of 1892-93, he found the cholera bacillus no fewer than 19 times in persons whose health was either not affected at all, or only very slightly. In six cases which were a longer time under observation, the cholera bacillus was found when the motions were perfectly solid and the persons in perfect health.

"That the results were due to errors of observation is improbable, for we meet the same conditions with regard to Diphtheria and even Tubercle."

"The more frequently and the more carefully researches are made, the oftener it is shown that healthy men harbour without ill effects, micro-organisms, which experiments on animals have shown to be virulent and specific."

"What positions are we to take up with respect to these facts? Shall we let them shake our faith in the etiological connection of the comma bacillus with cholera, of LEFFLER's bacillus with diphtheria, of the tubercle bacillus with phthisis. Seriously such a thing is out of the question."

"The error lies in the interpretation put upon the facts."

"That the pathogenic connection between man and the disease excitant, depends entirely upon the nature of the latter, while the man is merely an indifferent culture medium, is nothing less than a purely arbitrary hypothesis that bacteriology itself has made."

"When therefore objections, founded upon observed facts, are made to this young and powerful science, the fault is entirely its own."

"With the facts alone we have to deal. First of all it is clear that *infection and disease are not synonymous terms.*"

"We may freely grant that *infectious disease cannot arise without infection, but not the reverse proposition.*"

"*Every infection is not followed by disease, according to the popular saying, things that are injurious to one are not injurious to another.*"

"Were it true that the tubercle bacillus set up tuberculosis in every individual to whom it gained access, it would be indeed bad for the human race."

"But there is another condition necessary for the occurrence of disease as a consequence of infection, namely that the infected individual should be susceptible to the disease. Only the entire neglect of this condition could possibly have led to the one-sided notion of the term 'pathogenic' which has so frequently led us astray."

"It is altogether wrong to talk unreservedly of pathogenic bacteria, the circumstances of the case must always be borne in mind."

"The same may be said of the much vaunted term 'specific.' The failure of orthodox bacteriology consists in this, that it looked for the accident which caused the disease solely in the special nature of the living excitant, while in many cases the reverse is true, that the specificity of the attack lies in the reaction of the living tissue to the exciting cause."

From this standpoint the author investigated the question of susceptibility (predisposition), he agreed with GOTTSTEIN in giving it a variable value, according to the varying relations which the constitutional strength of man may bear to the energy of a special disease excitant.

This idea, which explains the causal connection between susceptibility to disease and the exciting cause of disease in infectious diseases, is not only limited to the latter, but represents a general principle which dominates the pathogenesis of internal diseases.

INSTRUCTION IN TROPICAL DISEASES.

THE *British Medical Journal* publishes the following circular letter, signed by the Permanent Under-Secretary of the Colonial Office and addressed to the medical schools:

Downing Street, 19th November, 1898.

SIR,—In the 5th paragraph of the letter from this Department of the 11th of March last, it was stated that Mr. Secretary CHAMBERLAIN, with a view to supplementing the instruction afforded by the medical schools, was endeavouring to make arrangements for giving to Colonial medical officers special clinical instruction in tropical medicine, such as is given at Netley and Haslar in the case of medical officers of the Army, Navy, and Indian Medical Services, and which, from lack of the necessary material, cannot invariably be given at the medical schools.

2. These arrangements have now been made. The directors of the Seamen's Hospital at the Albert Docks, which offers exceptional opportunities for studying cases of tropical disease, are providing the necessary buildings and teachers for the accommodation and instruction of the medical officers who may hereafter be selected by the Foreign Office and the Colonial Office for appointments in the tropics. A substantial contribution towards the initial cost of the buildings is being made by the Government, and it is hoped that by the 1st of October, 1899, it will be possible to receive medical officers at the hospital for purposes of instruction.

3. It is proposed that, as is at present the case, candidates for medical appointments in the British Colonial Possessions shall be fully qualified before they can be put upon the Secretary of State's list, that from this list a certain number shall be selected annually to fill the vacancies which may

occur in the Colonial Medical Service, that the selected candidates shall be trained for a period of at least two months at the Seamen's Hospital, and that they shall then be sent to the Colonies or Protectorates to which they have been allotted, where, when practicable, they will be attached, in the first instance, to the headquarters hospital for the purpose of gaining additional experience. In estimating the respective merits of candidates on the Secretary of State's list, regard will be had to the fact whether or not they have already received instruction in tropical medicine.

4. Judging from the replies which have been received from the General Medical Council and the medical schools Mr. CHAMBERLAIN believes that the above arrangements will prove acceptable.

5. Although the school at the Seamen's Hospital is designed for the training of medical officers for the Government Service, doubtless there will be many other medical men, such as the medical officers of missionary societies and trading corporations, and private practitioners who propose to settle in tropical countries, who will be glad to avail themselves of the advantages which such a school can offer.

6. The Colonies are being asked to make pecuniary contributions, to collect pathological material for use in the school, and to support the scheme in every possible way. So far, then, as this Department is concerned, no effort is being spared to make the school a success, and Mr. CHAMBERLAIN feels confident that the medical schools of this country will also do what is in their power to assist the development of an institution which is likely to be of general service, and to benefit medical science not only by giving a stimulus to the investigation of tropical disease, but also by qualifying a body of men to become investigators.

7. Mr. CHAMBERLAIN is so impressed with the importance of this subject as affecting the administration and well-being of the tropical Colonies that, in addition to this scheme for providing a thoroughly efficient Colonial Medical Staff, he wishes to encourage by every means in his power scientific inquiry into the causes of tropical diseases. Accordingly he has already, after correspondence with the Royal Society, instituted a Commission to study the subject of tropical malaria on the following lines:

8. The Royal Society has nominated two competent observers, who have already proceeded to Italy for a short preliminary study, and will afterwards go to some place in Africa probably, in the first instance, to Blantyre, in the British Central Africa Protectorate, where it has been ascertained that there exist good opportunities for carrying out the purpose in view.

9. In addition the Secretary of State has nominated an experienced medical officer of the Colonial Service to aid in the investigation. This officer will, in the first place, proceed to India in order to study under Surgeon-Major RONALD ROSS for about two months, so as to make himself acquainted with the result of that gentleman's researches. He will then join the other two observers in Africa, where they will together pursue their studies, which will probably occupy about two years, and report from time to time to a Committee in England, nominated jointly by the Royal Society and the Secretary of State.

10. Mr. CHAMBERLAIN has been glad to learn from the replies which have been sent to the letter referred to above that arrangements already exist, or are about to be made for giving special instruction in tropical medicine in upwards of twelve British medical schools, and he trusts that these schools, some of which (such as that of University College, Liverpool, University College, Bristol, and the University of Durham College of Medicine at Newcastle-on-Tyne), being

situated in large seaports, possess exceptional facilities for study of tropical disease, will keep in correspondence with the School of Tropical Medicine at the Seamen's Hospital, with a view to mutual assistance and advice.

11. In conclusion, Mr. CHAMBERLAIN desires to express his thanks to the General Medical Council and the British Medical Schools for the warm interest which they have taken in this matter, and for the ready and cordial support which they have afforded him. He will welcome any suggestions which may be made in furtherance of the object in view.

I am, Sir, your obedient servant,

EDWARD WINGFIELD.

UNIVERSITY WORK IN RELATION TO MEDICINE.

PARTICULARLY applicable to recent events in the University of Calcutta are some words uttered by Dr. MICHAEL FOSTER in the course of a delightful address on the above subject, delivered at the opening of Mason University College, Birmingham.

Discussing the education of the medical student in Physics and Chemistry, Dr. FOSTER argues that it would be less of a burden to the student to be taught to *understand* these sciences, to think in them as he expresses it, than to merely *know* them or be examined with a certain number of facts, but this only on the two following conditions.

"The first condition is that the authorities to whom is entrusted the appointment of the teacher, professor, call him what you will, of each of these sciences, should, in the selection of the holder and in the award of the emoluments of the chair, recognise, and that the teacher himself should recognise, that; the office is one not of teaching only, not of didactic exposition only, but of learning, of inquiry and research. I know very well that the gift, of investigation and the gift of facile exposition do not always, possibly do not often, go hand in hand. But the power of thinking in a science on which I have been dwelling is not taken in as drops falling softly from the lips of the teacher into the open mouths of the passively recipient hearer; it has to be gained by the exertions of the learner, and largely by active work in the laboratory. And I never heard of anyone having in him the true spirit of inquiry who in the quiet studies of the laboratory failed to carry his pupils with him onward from truth to truth, however sorry a figure he might cut when he attempted in a formal manner to thump the professorial pulpit. On the other hand, if the spirit of inquiry be lacking, an exposition clear as crystal, aided by elaborate diagrams or a projection lantern, while it seems to be wholly luminous, may leave the mind of the hearer really dark. The art of teaching in the true sense of the word is not the art of pouring into empty vessels; it is the art of awakening latent powers, the art of nursing that feeble infant, the desire to know, until, growing strong in limb, it is able to walk alone and go on its own way. The only teacher who can truly teach is one who is himself bent on going forward, to whom each bit of new knowledge which comes before him is not something to be stuck in its proper place in the catalogue of things known, but a stepping-stone from which to make a new stride."

EXAMINATIONS.

"The second condition is that the tests, trials, examinations, call them what you will, by which the progress of the student is measured, should be directed to appraising his intellectual growth, not his accumulated knowledge, to determining how far he has got on the road, not the amount of luggage he has gathered on the way."

We commend the above and indeed for the matter of that the whole of Dr. FOSTER's able, lucid, and original address to all thinking people, and more especially to those who are in any way connected with and responsible for the education of our youths.

Equally applicable is the following remark from the same source, which strikes straight at the abuses in our Indian Universities, where unfortunately the chief professional appointments are most commonly sought for the large and lucrative practice to which they lead.

"By all means, as I have already urged, let teaching and learning stand side by side; bid the teacher investigate and the investigator teach; but let the teaching be so ordered and so rewarded that the teacher has ample time and repose for his research, and, content with his hire, is placed beyond the temptation of giving up to the search for gold, the time and energy which ought to be spent in the pursuit of truth."

A SPEEDY WAY OF DILATING A RIGID OS IN PARTURITION

DR. J. FARRAR (Gainsborough) read a paper before the British Medical Association on the above.

The method consists in the application of a ten per cent. solution of cocaine to the os.

The efficacy of cocaine was discovered by accident in the following case. Dr. FARRAR says.

"I had been in attendance on a primipara on and off for some forty-eight hours. The os was thin, rigid, and obstinately unyielding; frequent attempts at stretching it, first with the finger then with a mechanical dilator, both with and without chloroform, and afterwards with indiarubber bags, had all proved futile; as had also the internal exhibition of approved medicaments, chloral hydrate, bromide of potassium, morphine, etc. In spite of these attempts, however, the os still remained firm, its margin feeling almost like a circle of sheet tin, and its orifice not larger than a shilling. The pains were very strong, frequent, and almost persistent, and the patient—who was, I should add, a deaf-mute—was losing self-control. The case was therefore becoming serious and as it was necessary that relief should be given without further waiting, I determined to incise the margin of the os. The woman being, as I have said, a deaf-mute, and exceedingly frightened and despondent at the condition of matters, I could not on the one hand, as in ordinary cases, talk and reason with her, and tell her what I proposed to do; and, on the other hand, I scarcely thought it prudent to further alarm her by the pain she would feel on the incisions being made, as this would probably make her quite unmanageable; and so, further, the administration of chloroform was contraindicated owing to symptoms of approaching exhaustion, I had only local anaesthesia left to me. The anesthetic I chose was cocaine. With a 10 per cent. solution of the hydrochloride on a piece of rag I smeared the os round and round, first on the outside and then within, finally leaving the rag between the margin and the head of the child. At the end of four minutes, by which time I considered anaesthesia would be sufficiently advanced for my purpose, judge of my astonishment—and, I may say, my gratification—when on introducing the scissors to make my limited incisions, I found the os had not only lost its rigidity, but that it was widely open, and as flexible and distensible as a rubber bag."

Dr. FARRAR had equally good results in four other cases, he strongly recommends this simple mode of procedure.

UNCLASSIFIED FEVERS OF THE TROPICS.

THE following is the classification of Tropical Fevers recently suggested by Lieutenant-Colonel A. OROMBIE, I.M.S., to the British Medical Association.

A PROVISIONAL SCHEME SHOWING THE PROBABLE POSITION OF THE UNCLASSIFIED FEVERS IN INDIA.

I Non-specific fevers of doubtful causation, probably climatic

a Ephemeral fever.

*b. Common continued fever.

1. Febricula. *Variety*: Nakra or nasha fever.

2. Simple continued fever.

*3. Ardent fever.

*c. Thermic fever, strisias, heat apoplexy.

*d. "Low fever"

II. Specific fevers of known or unknown origin :

1. Aphthous fever.

2. "Milk sickness"

*3. Urban continued fever.

4. Enteric fever.

*5. Non malarial remittent fever.

6. Malta fever.

*7. Double continued fever (Manson).

8. Relapsing fever.

*9. Acute febrile icterus

10. Yellow fever.

11. Beri-beri

12. Cerebro-spinal fever.

13. Typhus fever.

III. Malarial fevers.

1. Intermittent { Quotidian,
Tertian
Quartan

2. Remittent or continued malarial fever (Laveran).

IV. Fevers of compound origin :

*1. Typho-malarial fever.

*2. Kala-azar.

*3. Hæmoglobinuric fever (?)

"I have marked" he says "with an asterisk the clinical types which I would include under the heading of "Unclassified Fevers of the Tropics"

PLAGUE IN RUSSIAN TURKESTAN

THE fact that an epidemic of some unknown disease was raging in a village in the district of Jakender-kul, was first made known by a report from the Governor of Samarcand, dated October last.

Since then the disease has been identified as plague. The medical officer of Pendjikent who investigated the subject, reports, that a woman having died after a few days' illness in the village of Marzin, a native of Anzob a village some miles distant washed and buried the body, and then returned to Anzob where almost immediately she took sick and died after three days.

Next some of this woman's relatives and some of the people who had assisted at her burial took ill and died; then some of the inhabitants of the village became affected. The unusual mortality caused some excitement in the village and some one gave the unfortunate advice that the body of the dead woman should be exhumed as she had not been buried according to the precepts of Oheriat. This was done, but after it the epidemic spread with such rapidity that the matter was reported to the government.

Immediate measures were taken, Anzob was isolated and all the roads leading to it guarded, the clothes and bedding of the dead were burnt, the village was cleaned and disinfected and the sick isolated.

A cordon was placed round Anzob, and so far none of the surrounding villages have been attacked.

TRANSPORT FOR THE SICK AND WOUNDED.

WE have received a copy of a long communication from Brigade Surgeon Lieutenant-Colonel R. TEMPLE WRIGHT, I. M. S., addressed to "The President, Transport Committee, Simla, dated Ootacamund, Nilgiris, 1st September, 1898."

Lieutenant-Colonel TEMPLE WRIGHT is the inventor of the "Milver Ambulance Cart" which we learn was "awarded a medal at the Calcutta Exhibition of 1883."

For the "Milver spring stretcher," which we presume is intended for use with the "Milver Ambulance Cart" the inventor makes the following claims—"My stretcher is equally comfortable to the patient whether used in a common cart, a railway carriage, or on boardship, but I must own that at present it has been used only on deck, for the Captain of the steamer on which it was tried said he had no cabin large enough for it."

As the communication does not contain a detailed description of either the Ambulance Cart or the Spring Stretcher we are unable to discuss their merits.

We learn, however, that full particulars, with models and photographs, been forwarded to the President of the Transport Committee. We wish Lieutenant-Colonel TEMPLE WRIGHT every success as the result of his prolonged exertions.

THE MALARIAL MICROBE.

SAYS the *British Medical Journal* :—"A Rome correspondent of the *Corriere Sanitario* has sent the following statement to that journal in reference to Professor KOCH's opinion as to the cause of malaria

"According to the illustrious Berlin bacteriologist, the malarial agent is neither a bacillus nor a microbe, but a virus which mosquitoes belonging to a particular species produce and inoculate. Such virus is for these mosquitoes a natural and vital secretion, but is poisonous to the individuals inoculated with it. The insects which secrete the virus find the environment most favourable for them to live in, to develop, and to spread in those places that are called malarial and in those telluric, climatic, atmospheric, etc., conditions which characterise the malarial centres. The air, then, in malaria, cannot have so to speak, a greater or a more special effect than it has in many other diseases and we must even change the name of the disease, which responds to an absolutely erroneous concept, and up till to-day universally accepted in the scientific world and in public opinion.... Professor KOCH will continue his studies and experiments, which up to now have had such a happy result."

THE USE AND ABUSE OF MEDICAL CHARITIES

ACCORDING to Dr GARRETT HODDER the proposition of Hospital out-patients to 1,000 of the population in the given cities and towns is as follows

London and Dublin 371, Edinburgh 421, Portsmouth 42, Oldham 33, and Sunderland 31.

The following are the recommendations which he puts forward for the correction of abuses.

a. The desirability of abolishing subscribers' letters

b. The desirability of dispensing with patients' payments

c. The desirability of restricting treatment in the out-patient department to persons who really stand in need of hospital treatment

d. The desirability of forming an inquiry agency for the purpose of getting reliable evidence as to the means of persons who seek hospital treatment.

e. The desirability of converting the free dispensaries into provident institutions.

f. The desirability of forming a central council, under the auspices of the mayor and town council.

OPENING OF THE RAJKOTE CHEMICAL LABORATORY

At Rajkote on the 29th November, Lord SANDHURST opened the Laxman Meram Chemical Laboratory Institution which is probably unique in India. The object of the establishment is to improve the practice of native medicine, to make known valuable Indian remedies to Western science, and to ascertain which native herbs are most adapted to Western science. Eventually it is hoped to make progress in the direction of bacteriology and sanitary science. The cost of the building is Rs. 30,000 which is provided by AGAM LAXMANWALLA. The equipment has been provided by the joint fund of the Chiefs and the up-keep will be met from the same source. The Governor, in opening the Laboratory, said the practice of medicine on the European system had hardly got beyond a few large towns, and the systems followed by native practitioners had a long history and considerable literature. Among a good deal that to western notions might seem imperial, there must be included a large amount of valuable knowledge, especially as regarded the properties of indigenous drugs. This was a new departure in the field of research, and in this direction he looked for immense development, owing to the scheme under consideration which owed its inception to the great munificence of Mr. JAMSHETJEE N. Tata of Bombay.

ADVERTISING DOCTORS.

SAYS The *Medical Times and Hospital Gazette*.—"THERE can be no doubt that advertising pays. It is therefore little to be wondered at that many doctors advertise. The more respectable doctors consider self-advertisement undignified and improper. The less respectable have little regard for dignity and propriety, and look at the matter from a purely commercial standpoint. The result is that the inferior section of the profession gains at the expense of the more honourable, and there is a premium on unethical conduct. This ought not to be so. If it is wrong for doctors to advertise themselves, the General Medical Council is in a position to put a stop to it. If it is not wrong, that fact ought to be made clear. We should then all have a fair start in what is usually a pretty keen competition. Some of the veiled methods of advertisement not unknown to a certain class of well-known consultants are undoubtedly very difficult to get at, and will probably in many cases have to be left to the influence of medical and public opinion. But bold, open, and often dirty advertisements by doctors can easily be dealt with. We shall feel obliged if our readers will supply us with as full evidence as possible of any advertisements by doctors in order that we may bring the matter to a final issue. We should also be glad of the same in the case of registered dentists, many of whom are bad offenders."

DEATH OF A PASTEUR PATIENT.

A YOUNG man named O'LEARY, of the Indian Military Works Department, was bitten by a dog some three months ago in Mian Mir and proceeded immediately to the Pasteur Institute in Paris. He went through the prescribed twenty-one inoculations and returned apparently cured to Mian Mir, about three weeks ago, but died on the 27th November of hydrophobia. A peculiar point in the case is that the dog that bit Mr. O'LEARY is still alive, and has so far not shown any signs of rabies. Mr. O'LEARY was bitten just above the knee, and arrived in Paris with the wound healed up. This was looked upon as a bad point in the case, as the Professors insist on the wound being kept open. Mr. O'LEARY's wound had closed, and the Professors in the Pasteur Institute did not guarantee a cure on that account. It is very difficult to prevent a wound healing, during the long period between a bite from a rabid animal and a patient's arrival in Paris. But this is an absolute necessity for the Professors to guarantee a cure in the Pasteur Institute.

MILITARY ASSISTANT SURGEONS AND THEIR PROSPECTS.

REFERRING to a demi-official announcement that appeared in the lay press of India quite three months ago, the *British Medical Journal* received by last mail says:—

"It is satisfactory to know that the emoluments of a most useful class of public servants have been materially increased. The Secretary of State for India has sanctioned proposals submitted by the local Government for improving the position of Assistant Surgeons of the Subordinate Medical Service. The service will in future be divided into four classes, on Rs. 85, Rs. 110, Rs. 150, and Rs. 200 respectively, the existing class on Rs. 60 being abolished. Promotion will be given after certain fixed periods of service, the highest class being attained after nineteen years instead of the present average of twenty-four years. The Assistant Surgeons of the Subordinate Medical Department are often placed in position of considerable responsibility, especially when in sub-charge of military hospitals, where during the absence of military medical officers, they have, in addition to other duties, full disciplinary power over patients."

Now, much time has elapsed since this bit of "news" found its way into the daily papers, but no *Gazette* notification has up to the present date been made concerning it. Who is responsible for this strange and unaccountable procedure? Some body is to blame, but who? The blessings which the *British Medical Journal* speaks of as "have been", have in reality not been, and when they shall be, is apparently matter for future settlement. However let us hear no more of supposititious improvements. These announcements are aggravating, and if the Government is not prepared to carry out its promises, it is far better to preserve silence than to tantalise its subjects with vain hopes.

THE GROSE MEMORIAL. A MEDICAL PRIZE.

IT is very gratifying to learn that a fund has been raised by members of the India Civil Service serving in the Madras Presidency for the purpose of founding a prize in memory of the late Mr. JAMES GROSE, who died at Ootacamund on the 7th June last. "The Grose Memorial Prize" will be awarded to the female student of the Madras Medical College standing first in the first College examination for the degree of medical practitioner. The total sum collected amounts to Rs. 667, which has been invested in $\frac{3}{4}$ per cent. Government paper, and the Committee, consisting of the Honorary Sir HENRY BLISS, the Honorary Mr. STURROCK, and Messrs. J. H. TREMENEERE, H. A. SIM, and A. G. CARDEW, has intimated to the Director of Public Instruction its willingness to hand over the fund requesting that Government may be moved to sanction a grant-in-aid equal to half the sum raised. The total endowment would then amount to Rs. 1,000 which would yield an Annual return of Rs. 35, which it is hoped will be considerable sufficient for the prize proposed. The Government has accepted the endowment with pleasure, and a half grant of Rs. 333-8-0 in aid of it. The Director of Public Instruction and the Principal of the Medical College are to be trustees for the endowment.

A NEW MEDICAL MAGAZINE.

THE Grant Medical College has, writes the *Bombay Gazette*, started a magazine of its own. The editor explains in his preliminary greetings that the object of the publication is to encourage sport, and to record the progress of the College Gymkhana. But it has a broader object than that, for it treats of subjects calculated to improve the reader's mind to teach him what he wants to know ere he can become a medical practitioner. For instance, one article in the magazine is headed "A few remarks on some of

the difficulties met with by students while administering chloroform," in which the writer gives some interesting reading on the subject of his experience of chloroform. Then follows a paper entitled "A peep into the post-mortem room," after which Colonel HATCH discourses on "the successful removal of an ovarian cyst," a most remarkable case, which is fully described by the writer.

A NEW DEPARTURE FOR CANDIDATES FOR THE ARMY WARRANT MEDICAL SERVICE.

By a recent order of the Government of India, Captain MARCUS T. COX of the Calcutta Volunteer Rifles, Pioneer Company, a West Indian gentleman of respectability, a good citizen, a splendid sample of his race, has been permitted to allow his son to appear in the next competitive examination for candidates for the Warrant or Military Assistant Surgeon branch of the medical service of the Army, in appreciation of Captain Cox's excellent services as a Volunteer Officer in the Manipur expedition. Master COX is an undergraduate of the Calcutta University and has very worthy credentials from the Rector of St Paul's School, Darjiling. We congratulate Captain Cox for this special mark of esteem from the Indian Government, and we think, the step will prove that the Director General, I M S, and the Military authorities of the British Army have not acted unwisely, as Master COX is sure to do credit to their choice, for he is the worthy son of a gallant father.

QUACKS AND THE LAW.

ONE is glad to see that the new Coroner has a sense of justice, and that he committed a man to the sessions for giving medicine to a man who afterwards died. One hopes in spite of the Standing Counsel's efforts to screen this criminal, that Mr WIGLEY will go on doing his duty, and not rest till every single person guilty of this offence, which one is sorry to see is increasing rapidly in Calcutta, is brought to justice. If a man causes the death of another man, we know of no exception in the Penal Code which excuses him merely because he did not know better, nor is there any section of Penal Code, which we are aware of, that excuses a man from the results of homicide because he is a member of the College of Dentists, and, to use an Irishman, puts initials after his name instead of in front. In fact the only result of this case is that, as HAKERPHAM observes, though it may make the unskilful laugh, it cannot but make the judicious grieve.

ANGLO-INDIAN MEDICAL WOMEN

MISS D. E. PRATT, formerly a student of the Calcutta Medical College and afterwards Assistant Surgeon at the Lady Lyall Hospital at Agra, has been selected for the charge of the new hospital which the Maharaja of Kashmir is building at Srinagar in connection with the Dufferin Fund. Miss PRATT, who has recently been home and taken the higher degrees in medicine, is now on her way out to join her appointment. Among other lady doctors possessing English qualifications who originally studied at the Calcutta Medical College, and who are now in charge of important hospitals, may be mentioned Miss L. BLOND at Bhopal, Miss L. SMITH at Nagpur, Miss I. E. SYKES at Lucknow, and Miss FRIEDL PERLINA at Chittagong. Miss R. O'HAN, who preceded home about two years ago, having been given Lady ELGIN'S Jubilee Scholarship of £100 after a brilliant career in the Calcutta Medical College, recently gained her degree in Ireland.

THE PARKES MEMORIAL PRIZE.

SAYS the *British Medical Journal*—"The subject for the next Parkes Memorial Prize, which is open to medical officers of the Royal Navy, Army, and Indian Medical Services of executive rank on full pay (with the exception of the Assist-

ant Professors of the Army Medical School during their term of office) is Venereal Diseases in the British and Indian Armies. Their Prevalence and Prevention. Essays, which must be illustrated as far as practicable from the personal experience of the writer, must be sent to the Secretary of the Parkes Memorial Fund, Royal Victoria Hospital, on or before December 31st, 1900. Each essay to have a motto, and to be accompanied by a sealed envelope bearing the same motto, and containing the name of the competitor.

NEW MEMBERS OF THE INDIAN MEDICAL ASSOCIATION

THE following gentlemen have joined the Association since our last publication—

Claude R. Woods, M.D., C.M., Ujjain Railway Station
M. O. Mukerji, L.M.S., Assistant Surgeon, (Sirmoor State) Nahan.

R. L. D. Gupta, V.L.M.S. Central Medical Hall, Raipur.
V. Narayana Menon, C.M.S., Road Frontier Inspection Station, Nagaldime, Bellary District
William Forrester, M.R.C.S. Eng., L.R.C.P. Lond., Civil Surgeon, Gurgaon.

H. L. O. Fleming, D.M.C.C., Assistant Surgeon, Fort Fulta vice Debipur.

NEW MEMBERS OF THE INDIAN MEDICAL ASSOCIATION PROVIDENT FUND.

THE following gentleman have joined the I.M.A. Provident Fund as associate members since our last issue—

William Forrester, M.R.C.S. Eng., L.R.C.P. Lond., Civil Surgeon, Gurgaon.

Dr A. J. Ignatius, No 22, Simpsons Road, Rangoon

HAFFKINE'S PLAGUE INOCULATION AN ADMITTED FAILURE.

A notable feature of Professor Haffkine's evidence before the Plague Commission is the candour with which he admits that all his efforts in the direction of curing plague by means of his serum have failed. Indeed, he goes further "On comparing the mortality among those who passed through his hands with those who were treated in the ordinary manner, it was found that the mortality was *greater* among the patients who passed through his treatment." The curative treatment ought, of course, to be carefully distinguished from the preventive treatment, the efficacy of which has never been seriously disputed.

MORE DOCTORS FROM ENGLAND. INDIA GOES TO THE WALL.

The Indian Government have asked for ten more medical men to serve temporarily on plague or general duty in Madras. Of these, four have already been appointed Volunteers who may be ready to start for India at two or three days' notice are invited to send their names to the Revenue Secretary, India Office, White Hall. Candidates must be under forty years of age. Other information may be obtained on application.

SHORT ITEMS AND PERSONALITIES

It is with much satisfaction says the *Lancet* we are enabled to inform our readers that His Royal Highness the Prince of Wales has now made an excellent, and, we may really say complete recovery from the severe accident which he met with in July last, and after the interval which has elapsed of more than four months, the cure may be reasonably considered permanent.

"I am glad to find you better," said John Hunter, the famous surgeon, to Foote, the equally famous actor, one morning,

THE INDIAN MEDICAL ASSOCIATION.

ESTABLISHED AND REGISTERED 1894.

OFFICE AND LIBRARY:

50, Park Street, Calcutta.

TERMS OF MEMBERSHIP

Every man or woman, who being duly and legally qualified to practice medicine, by virtue of holding a degree or diploma or qualification in medicine, whether British, Indian, Colonial, European or American, whether from State Institutions or Independent Medical Schools, and every person holding a Government Certificate entitling such person to practice Medicine in any official or private capacity, shall be eligible for election to Membership in the Association.

Every person desirous of becoming a member, shall send an application in the form given below, to the Secretary of the Association, and the Council shall consider and dispose of same at their next meeting. On any person being elected a member, an intimation to the effect shall be notified in the Journal of the Association, and on payment of the subscription, a certificate of membership shall be issued.

Application for Membership.

I, _____, residing at _____, am desirous of being elected a Member of the Indian Medical Association; and I agree to pay the subscription, and to conform to the Rules and Regulations now existing, or which hereafter may be made by virtue of the same.

Name..... Address.....
Professional title..... Date.....

Every Member shall pay a subscription of five rupees per annum which shall entitle him to all the privileges of membership. The subscription shall be considered due in advance on the 1st January in each year, and should be forwarded to the Treasurer.

The *Indian Medical Record* is the Journal of the Association, and is the medium of communication between Members of the Association. In it shall be inserted the Transactions and Proceedings, and all notices of meetings of the Association, and any other business which the Council deem necessary.

The Reading Room and Library of the Association are open to all members of the medical profession from 10 A.M. to 5 P.M. daily (except Sunday.)

Members who have paid their subscription to the Association, may obtain their membership certificates and copies of the First, Second and Third Annual Reports of the Association by applying to the Secretary. Name and address to be plainly written.

Officers and Council:

President:—Lal Madhab Mukerji, Rai Bahadur, L.M.S., F.C.U., Principal, Calcutta Medical School.

Vice-Presidents:—(1) E. W. Chambers, L.M.S., L.S.A., Lond.

(2) H. H. Sir Bhagwat Singhjee, G.C.I.E., M.D., C.M., F.R.C.P. Edin., LL.D., D.C.L. Edin., Thakore Sahab of Gondal, Kathiawar.

Members of Council:—Representing Bengal and resident in Calcutta (4 members).

1. H. W. Jones, M.D., M.B.C.S., Eng.

2. J. G. Anderson, G.M.C.B.

3. K. G. Sircar, M.B., L.R.C.P., Edin.

4. Bakhal Das Ghose, L.M.S.

Representing—

5. *Bombay*.—Alfred McCabe-Dallas, L.M. Dub., L.R.C.P. Irel.

6. *Madras*.—O. G. B. Naylor, M.B.C.S., L.R.C.P., Lond.

7. *Central Provinces*.—Mirza Karim Khan, M.B., C.M., Edin.

8. *Punjab*.—Professor O. C. Caleb, M.B., M.S.

9. *N.W.P. and Oudh*.—John Morton, M.D., L.R.C.P. & S. Edin.

10. *Burma*.—N. N. Parakh, L.S.A. Lond., L.F.P.S. Glas.

11. *Independent Native States*.—A. Mitra, Rai Bahadur, L.R.C.P. and S. Edin.

12. *Assam and Duars*.—Wm. Brown, M.B., C.M. Glas.

13. *Representative of Military Assistant Surgeons' Service*.—Major James Forsyth, S.A.S., H. E. The Viceroy's Staff.

14. *Representative of Civil Assistant Surgeons' Service*.—Hari Datt Pant, L.M.S., Assistant Civil Surgeon, Gonda, Oudh.

15. *Representative of Hospital Assistants' Service*.—J. M. Philip, C.M.S., Government Ophthalmic Hospital, Madras.

Treasurer.—Major H. C. Hodgkins, S.A.S., Medical College, Calcutta.

Secretary.—James B. Wallace, M.D., F.R.C.S., Editor, *Indian Medical Record*.

Solicitors.—Messrs. Dignam and Co., Attorneys-at-Law, High Court, Calcutta.

Bankers.—Messrs. Grindlay and Co., Calcutta.

RULES AND REGULATIONS OF THE INDIAN MEDICAL ASSOCIATION PROVIDENT FUND.

I. The Fund shall be called the Indian Medical Association Provident Fund.

II. The Fund shall be registered under Act XXI of 1860, and the Registered Office shall be situated in Calcutta.

III. The object of the Fund is to give members of the medical community in India and Burma an opportunity of making provision for their families on the mutual benefit system.

IV. Any medical man or woman, may become a member of the Fund.

V. The Fund shall consist of two classes of subscribers, namely, (a) those who are members of the Association called Associate members, and (b) non-members of the Association called "non-associates." The subscription in each class shall be as follows:—

(a). Every non-associate shall, on joining, pay an entrance fee of Rs. 10, which shall be credited to the capital of the Fund.

(b). An annual subscription of Rs. 6 shall be payable by every non-associate member which shall go to meet the working expenses of the Fund.

(c). Members of the Association will pay no entrance fee and no annual subscription. They will pay only their fee of Rs. 5 as members of the Association and the "calls" of Rule (d).

(d). On the decease of any member, a call of Re 1 per head will be made on all the other members of the Fund of both classes.

(e). To meet such calls, members of each class shall place in deposit in the Fund, a sum of not less than Rs. 3 at a time, to be renewed before the last rupee on hand has been paid on his account.

(f). Notice of the payment of a call shall be given by a post-card, and through the *Indian Medical Record*, which shall contain a statement of the sum paid on account of the member to whom it is addressed, and of the balance to his credit held in deposit in the Fund, and this shall be deemed a sufficient receipt for the payment of the call.

VI. The nominee or nominees of each subscriber shall, at his death, receive a bonus calculated at the rate of Re. 1 per head for each and every registered subscriber of the Fund, and who has a deposit in the Fund to meet the call.

VII. The claims of nominees in each class shall be paid as follows.—One-half on submission of certificate of death and surrender of entrance certificate (Rule X), and the remaining half, in accordance with the terms of Rule VII, after the claim is admitted by the Directors in meeting.

VIII. Applications for admission to the Fund must be made on a prescribed form which shall contain clearly written:—

(a). The full name, age, and address of the applicant.

(b). The class he wishes to join.

(c). An engagement on his part to submit to and abide by the rules of the Fund.

(d). The name, age, and address of the nominee or nominees for whose benefit he joins the Fund.

(e). And in the case of nominees who are minors the names and addresses of two or more guardians other than the subscriber, appointed in each case, to whom the bonus will be paid.

Every application must be accompanied by the entrance fee specified in Rule V (a), or by a postal money order or cash as subscription and "call" deposits due from associate members.

IX. A certificate of membership in the form prescribed shall be issued to each subscriber by the Secretary and Treasurer as soon as his name has been registered. This certificate may be renewed in favour of a fresh nominee on payment of As. 8 and surrender of original certificate. On a like payment being made, a duplicate certificate may be granted when the original is lost or destroyed.

X. Claims for payment must be submitted on a prescribed form containing a certificate of the death of the subscriber, signed by a duly qualified medical practitioner,

according to priority of application, on a formal identification of the nominee, who shall be required to surrender the entrance certificate granted under the preceding rule.

XI. Every subscriber shall keep the Secretary and Treasurer of the Fund duly informed of any change in his address. If he fails to do so, he shall have no cause of complaint against the Fund for any disadvantage arising from such neglect.

XII. Any subscriber who fails to renew his deposit for payment of calls before it has been exhausted, and so cannot meet a call under Rule V (c) nor the subscription specified in Rule V (b or c) within the year for which it is due, shall, after reasonable enquiry, be adjudged a defaulter, and shall forfeit all claims upon the Fund. Nothing in this Rule, however, shall prevent a subscriber, whose name may have been struck off as a defaulter from joining the Fund as a fresh member on payment of all arrears.

XIII. The Fund shall be managed by a President and three Directors resident in Calcutta, nominated by the Council of the Indian Medical Association from amongst their own members.

XIV.—An Auditor, who shall be a Councillor other than a Director, shall be elected annually by the Council, the accounts being submitted to such Auditor quarterly for audit.

XV. The half-yearly Report of the Fund shall be published in the *Indian Medical Record*, after it has been placed by the Directors before the Council of the Indian Medical Association.

XVI.—The Annual Report of the Fund shall be placed before the annual meeting of the Indian Medical Association.

XVII.—Any member of the Fund having a grievance against the Directors or Treasurer of the Fund may appeal to the Council of the Association for a consideration of his case.

XVIII.—The Directors shall meet once a quarter for the transaction of business, and shall have power to make, vary, or repeal bye laws for the regulation of the affairs of the Fund, subject to approval at the next annual general meeting of the Association.

XIX.—All receipts, except sums credited to Working Expenses Account, shall be paid into the Bank of Bengal. When the sum accumulated in the Bank to the credit of Capital Account, in excess of the amount required to meet a call, admits of the purchase of Government Securities, an investment shall be made, and the interest obtained therefrom credited to Working Expenses Account.

XX.—When any question arises which, in the opinion of the Directors, should be referred to the whole body of subscribers, or which involves the repeal or alteration of or addition to, any of the rules of the Fund, the votes of subscribers shall be taken thereon, and the question so referred shall be decided by the majority of the votes received within one month from the issue of the circular.

FORM OF APPLICATION FOR ADMISSION.

TO THE SECRETARY AND TREASURER,

Indian Medical Association Provident Fund, Calcutta.

DEAR SIR,

(Station) ————— 189 .

I,

hereby apply to be admitted as (1) ^{associate} ~~non-associate~~ member of the Indian Medical Association Provident Fund, Calcutta, on behalf of my (2) _____

now _____ years of age, residing in _____ and I bind myself to submit to, and abide by, the Rules and Bye-laws of the said Fund.

I also agree that all claims on the above Fund shall be forfeited by my nominee, should I neglect to pay my dues.

I forward herewith Rs. _____

Yours faithfully,

Usual Signature and Address _____

(1) Score out one word or the other to indicate which class you join.
(2) Here state relationship. No minor will be accepted as a nominee unless two or more guardians appointed, to whom the bonus secured will be paid, the name and address of each guardian being clearly written on the back of this form.

(PLEASE WRITE CLEARLY.)

Guardians appointed for nominees named on page _____

"You followed my prescription, of course?" "Indeed I did not, Doctor," replied Sam, "for if I had done so I would have broken my neck." "Broken your neck!" exclaimed Hunter, in surprise. "Yes," said Foote, "for I threw your prescription out of a three-story window."

I wish once more to express the opinion that the next advance in the treatment of fibroid tumours will be the general adoption of early operation and the more general substitution of myomectomy for hysterectomy, as being the most conservative treatment of these growths.—Charles P. Noble.

The Travancore Durbar Physician has applied to the Secretary to the Surgeon-General with the Government of Madras, for a supply of plague serum sufficient to inoculate a thousand persons. He has also written to Paris for a supply of serum to inoculate seven thousand persons.

According to an editorial in the *Therapeutic Gazette* for October 15th, Dr. H. P. Loomis says that one can not but be impressed with the moral effect which hypodermic injections have on some patients. He has seen, in neurotic patients, fever leave and weight increase under daily hypodermics of water.

Many a man carries gonorrhoea latent for years. The seminal vesicles may become specifically inflamed and be a source of reinfection or of innocently infecting others. The microscope should be used to verify the case and the examination made after stripping the vesicles.

Dr. Baldy teaches that in a slow involution of the womb after miscarriage or abortion, as well as in subinvolution after labor, the daily irrigation of the uterine cavity with a gallon of a mild alkaline antiseptic solution of a high temperature, 110° to 115° F., promotes prompt involution.

In a case of persistent headache, Dr. Vansant demonstrated the great value of careful inspection of the nasal chambers and the removal of all accumulations of discharges from the sinuses, followed by the local application of heated air, which afforded immediate relief.

We much regret to have to announce that Sir John Banks, K. C. B., Regius Professor of Medicine in the University of Dublin has resigned that position which he has for so many years filled with such distinction. The Board accepted his resignation with great regret.

Major J. Watson, R.A.M.C., attached to the Station Hospital, Agra, has been appointed to the medical charge of the Station Hospital at Darjiling, *vice* Major R. R. H. Moore, R.A.M.C.

The highly successful Fancy Fair which was organised by Lady Collen in aid of the Ripon Hospital at Simla, in October last, has resulted in a sum of Rs. 21,000. The money will be utilised in supporting a free ward for poor Europeans.

The Government of India has suspended the order calling out 100 doctors for field service, but they have been warned to be in readiness to start at a moment's notice should any contingency arise.

Tying a catheter into the urethra is one of the most effectual methods of preventing the occurrence of rigors of Urthral Fever, a fact that is quite inexplicable if rigors are caused by reflex irritation of the deep part of the urethra.

Among the list of successful candidates for the first Professional examination for the diploma of Fellow, we see the name of Shapurji Hormasji Modi, M.B.C.S. Eng., L.R.C.P. Lond. L.M.S., Bombay, Grant Medical College.

Captain Hubert Mallins Earle, M.B.C.S. Eng., L.R.C.P. Lond. (1890) has been appointed Officiating Resident Surgeon to the Eden Hospital, Calcutta, *vice* Stevens "wintering" in Darjiling.

Lieutenant-Colonel T. Grainger, M.D., I.M.S., has been appointed to act as Civil Surgeon of Chumparun, during the absence, on deputation, of Major R. R. H. Whitwell, I.M.S.

Surgeon William J. Maillard, Royal Navy has received the Victoria Cross for gallantry at Candia during the massacre.

A report seems to have been circulated that Sir Joseph Fayrer intended retiring from practice, the *Lancet* in its last issue contradicts this.

"How to ride the bicycle" by Joubert, is the latest book on the "wheel." Clear the way for Brookes' Soup.

Nearly sixty persons are killed in this country by snakes every four and twenty hours.

NOTICE.—Subscribers are requested to communicate any temporary change of address, not to the Office of this Journal, but to the Post Office, through which they are accustomed to receive their Journals.

MEDICINE.

Conjugal Diabetes.

DR. SCHRAM, before the Harvard Medical Society of New York City, is reported in *Medical News*, as saying that in a series of 5,000 cases, ROISUMEAU found 1.8 per cent. of conjugal diabetes. Most investigators agree that the development of the disease in both husband and wife is not accidental, but that an etiologic relation exists. The facts thus far published do not shed much light on the two theories of causation now held, viz: That the ordinarily accepted causes of diabetes are active in both husband and wife, and that the disease is contagious. Cases have been reported with almost conclusive evidence of contagion, but the nature of the contagium and how it is conveyed are mysteries. In regard to the doubt which has been expressed as to contagion in diabetes, I would like to mention some recently reported cases in which laundresses apparently contracted the disease by washing the clothing of diabetics. However, the question is still an open one. The authorities differ very much, but the French school is inclined to believe that diabetes is contagious. Dr. SCHRAM reports the case of a woman, aged 76 years. She first came under observation seven years ago, and had been married forty-eight years. Sugar was constantly found in the urine in amounts varying from less than 1 to 4 per cent. She refused to submit to rigorous diet in July, 1897, in diabetic coma. Thirst and pruritus had been the most troublesome symptoms. An extensive ischio-rectal abscess developed two weeks before death. One week later the husband's urine was found to contain 3 per cent. of sugar. Symptoms of the disease sufficient to attract his attention antedated his wife's death by about two weeks. Sugar is now found in his urine in abundance, but disappears for a time under diet and opium. He is now 76 years of age and apparently contracted the disease seven years after it was first discovered in the wife, and after nearly fifty-three years of married life. The couple had eleven children, seven of whom are alive and well.—*Jour. Amer. Med. Assoc.*

Beechwood Creosote in Phthisis

MR. CHARLES LAMPLOUGH thus sums up the results of his observations on one hundred cases of pulmonary tuberculosis treated with large doses of beechwood creosote:

Having compared the objections raised against the administration of beechwood creosote in phthisis with the results obtained at this hospital by treating one hundred cases with this drug, I would suggest that the following points are worthy of consideration and further investigation.

1. The best beechwood creosote can be given with benefit, in amounts varying from one hundred and twenty to two hundred and forty minims daily, in cases of pulmonary tuberculosis.

2. The drug is best administered in cod-liver oil or in a spirituous solution, and in some cases the "creosote chamber" or oro-nasal inhaler may be ordered in addition, with advantage.

3. The dose should be small at first, but it can be rapidly increased to forty minims three times daily for an adult. In three cases doses of thirty minims three times a day were well borne by children.

4. Large doses rarely cause any gastric disturbance: on the contrary, the appetite is frequently increased, symptoms of dyspepsia disappear, and cod-liver oil is more easily assimilated. The cough, expectoration, and night sweats are diminished, and the physical signs improved.

5. Owing to its disinfectant action in the alimentary canal the drug probably diminishes the risk of tuberculous enteritis by self-infection when patients swallow their sputa, but owing to the increased peristalsis which is created by creosote, it is usually contraindicated in cases where the ulceration is already advanced.

6. The drug does not tend to cause hæmoptysis, but rather to prevent its recurrence.

7. Creosote does not irritate the normal mucous membrane of the genito-urinary tract.

8. Owing to its extremely small cost pure creosote can be given to a much larger number of patients than the carbonates of creosote and guaiacal, which respectively cost four times and twelve times as much as the older drug.—*N. Y. Med. Jour.*

Association of Hysteria and Epilepsy.

THE expression "hystero-epilepsy," introduced by CHARCOT, in no way applies to the occurrence of epilepsy and true hysteria in the same subject. JOFFEY points out that these two diseases are sometimes combined, and that this combination often presents somewhat unusual features. Thus, he quotes the case of a girl who presented two forms of crises, the one characterised by vertigo coming on instantaneously without any precursory sign, and disappearing suddenly. At other times there was a preceding gastric aura followed by loss of consciousness for some seconds. The other form was preceded for a considerable interval by a condition of *malaise* with very marked sensation of globus, ending in a marked hysterical seizure, at times accompanied by loss of consciousness. Should this not occur there was a violent attack of crying. At the same time various stigmata were present, such as ovaralgia, complete left hemianæsthesia, loss of taste and smell on the same side. There is thus no doubt as to the occurrence of hysteria in the case, and it is no less certain that true epilepsy was present as well. JOFFEY quotes another example in which there was always an attack of hysteria major, followed by a state of drowsiness similar to that found in epilepsy. In other instances the epileptic seizure may precede the hysterical attack. The author finds that the administration of bromide modifies markedly the epileptic condition in such a manner that the case retains only the hysterical element. A noteworthy point seems to be that bromide treatment does not appear to reduce the frequency of the seizures, exerting its effect merely upon the epileptic element.—*Brit. Med. Jour.*

Clinical Value of Diphtheria Antitoxin

Administered per Os.

BY DR. J. ZABORSKY, The conclusions reached by the author from cases reported are as follows:—

1. Diphtheria antitoxin acts similarly whether given by the mouth or subcutaneously, but its effects occur much later when given in the former way.

2. It is possible that the intestinal epithelium refuses, at certain times, to take it up, and, therefore, it is a less reliable method.

3. This mode should be employed in mild cases when objections stand in the way of its hypodermic use. It may be used in mild cases in adults.

4. Its use by the mouth as a prophylactic measure is to be recommended, as it presents many advantages. However, if the child has been exposed to diphtheria for as much as two days, the hypodermic method should be employed.

5. Joint pains, erythema, urticaria, and dysmenorrhæa are not prevented.

6. From a clinical standpoint, therefore, it is to be urged that for curative purposes, the administration by the mouth should be restricted to exceptional cases; but for prophylactic purposes this method should receive the preference.—*N. Y. Med. Jour.*

SURGERY.

Abuse and Danger of the Nasal Douche.

THE author has written a sensible article on this subject. He speaks of the very common practice of douching the nose for its every apparent ill, without first examining to know if douching is indicated. He says: "It has been prescribed by general practitioners to every patient who complains of having to blow his nose too often; to every one who has a feeling of the nose being stopped up, and for the relief of genuine obstruction of this organ, though it be a deflected septum or new growth in the nasal cavity." These remarks apply with equal force to the abusive employment of the retro-nasal douches.

Aside from the inadequacy of universal douching, its disappointing and depressing effect upon hopeful patients, there are dangers that attend its misuse. Liquids charged with carbolic acid, alum, zinc salts, etc., even in weak solutions, are highly injurious. Pure water is badly borne.

The only harmless liquids—as shown by ARONSOHN—are those formed by the physiological solution of sodium chloride (0.73 per cent.), of sodium bicarbonate (1.46 per cent.), of sodium sulphide (2.92 per cent.), etc., and these solutions become injurious when much weaker or stronger than this.

Injury is done to the mucous membranes and olfactory nerves by antiseptic douches. Distressing headaches are caused by improper use of even proper medicaments in the nose. Sinusitis and otitis media may be caused by forcing irritating and unsterilized liquids and purulent secretions into the accessory cavities when douching is done most carefully. The surgeon should first investigate and determine the cause of catarrh. Obstructions in the nose should be removed and explicit directions given each patient who is to use the douches.

That "cleanliness is next to godliness" is demonstrated in nasal surgery. Good results follow good treatment, and good treatment embodies perfect cleanliness, so far as it can be secured.—Dr. LIGHTWITZ in *Post-Grad.*

Influence of Age, Sex, and Race in Surgical Diseases.

DR. W. I. RODMAN, of Louisville, read a paper with this title. The author said that negroes were practically immune from varicocele. An analysis of five hundred cases operated upon showed not a single instance of this condition in negroes, there being only one case encountered in a mulatto. Extensive correspondence by the author with eminent surgeons in large Southern cities had corroborated this statement. The colored race was far less frequently affected with gall stones than were the whites. Of one hundred and six cases of gall stones not one was met with in the negro. Tetanus was more frequent in negroes than in whites. The causes for this were given. Enlargement of the prostate was comparatively common in the white person after fifty, but was rarely seen in the negro. The author had searched the records of the Louisville Hospital for ten years, but had been unable to find a single case of enlarged prostate in the negro. Congenital deformities, such as harelip, cleft palate, spina bifida, etc., were far less frequent in the negro, according to the experience of Southern practitioners, than in whites. Not a single case of harelip or of cleft palate in the negro had been operated on in the Louisville Hospital for the last ten years. The speaker had never encountered clubfoot or spina bifida in the negro in the last ten years. Other surgeons corroborated him as to the rarity of these affections in the negro race. Very few cases of erysipelas occurred in colored persons. Aneurism, on the other hand, was far more common, almost three to one, in

the colored than in the white race. Three times as many cases occurred in men as in women. Stone in the bladder was much more frequent in the white than in the negro race.—*Med. Rec.*

Direct Transplantation of Muscles in the Treatment of Paralytic Deformity.

IN a large number of cases of infantile paralysis, involving the thighs, the tensor vaginae femoris and the sartorius escape, the lower extremity becoming flexed and adducted. To overcome this deformity and utilize the sartorius, Goldthwait has five times attached its lower end to the tendon of the quadriceps femoris just above the patella. Three cases were improved, and two failed owing to the giving way of the sutures. The author also reports a case in which he attached the common extensor and tibialis anticus in the lower part of their course, to overcome deformity consequent upon tibialis anticus paralysis.—*Olin. Jour.*

Acute Otitis Media.

THE following simple device, always convenient give grateful relief: A piece of cotton is placed lightly in the mouth of the canal. A pipe is filled with tobacco and lighted. Then a piece of clean cloth is placed over the mouth of the pipe bowl and gently blown through, while the lip piece of the warm stem rests against the cotton pledget. This filters the warm smoke through the cotton into the canal, and a grateful sedative effect is soon obtained. The author does not remember having seen this remedy mentioned in books, but has witnessed its efficacy in the absence of other remedies. The practice indulged in by the laity of pouring oils, etc., into the ear is a vicious one, since these become rancid, irritate, and predispose to a subsequent inflammation. Poulticing is also bad, for it favors suppuration and perforation of the drumhead.—*Med. Rec.*

Large number of Foreign Bodies in the Stomach: Gastrotomy.

IN the *Journal of the American Medical Association*, Dr. A. H. MEISENBACH has published the case of a man, aged twenty-two years, terming himself "the human ostrich," who had for nine years followed the "profession" of swallowing glass, metal, &c. He suffered no discomfort until the end of that period when he complained of pain in the stomach. Whilst standing a mass of about the size of the hand could be felt in the umbilical and hypogastric regions which could be raised and which descended with an impulse. When recumbent as he turned from his back on either side the mass moved towards that side. A skiagraph showed a shadow in the umbilical region. Gastrotomy was performed and 118 articles, besides about an ounce of broken glass, weighing in all 1 lb. were removed. The articles were: 27 staples, 15 screws (1 in. and 1½ in.), 52 nails (2 in. and 1½ in.), 21 cartridges, 2 pocket-knife blades, and 2 inches of brass chain. The patient recovered but an attack of pneumonia of the right base followed the operation. Dr. MEISENBACH attributes this to the X-rays, to which the patient had been exposed on several occasions for long periods. X rays dermatitis is now well-known and deep-seated injury has also been claimed as an effect. Dr. SORREL, a French surgeon, has already asserted that pneumonia can be produced by the rays; other writers mention periostitis. The retention for such a long period of this extraordinary collection of foreign bodies in the stomach without injury and even without symptoms is remarkable.—*Lancet.*

OBSTETRICS AND GYNÆCOLOGY.

Rupture of the Uterus, probably Traumatic, in Third Month of Pregnancy.

HIVER related the following case:—A patient, aged 41, multipara, was admitted to the Hospital Necker on 22nd March and died half an hour after admission. There had been amenorrhœa for three months and a half, violent pains for three days. On 21st March symptoms of internal hæmorrhage set in, and a voluminous fluid tumour was found in the posterior and left lateral *cuisse-de-sac*. The necropsy showed acute peritonitis. The two layers of the left broad ligament were separated by a large collection of fluid which had passed anteriorly between the uterus and bladder, raising the peritoneum, and posteriorly passed up into the lumbar region, following the utero-ovarian vessels. The uterus was three finger's breadths above the symphysis pubis; the appendages were normal. On incising the outer border of the left broad ligament, a foetus of 3 months with its membranes was found in the midst of a quantity of blood clot, and on washing out the cavity a circular perforation of the uterus, as large as a 5-franc piece, was found, forming a communication between the uterine cavity and the cavity in the broad ligament. The vagina was intact. In explaining the condition, the author excludes pathological alteration of the uterine walls, for these were found healthy; also external injury, for these had been none; also spontaneous rupture, for no case has ever been recorded so early in the pregnancy, and concludes, therefore, that the perforation was due to injury of the uterus from within, probably by a rigid sound. Most likely the orifice of rupture was at first narrow, and widened out, under the influence of uterine contractions, sufficiently to allow the passage of the foetus and its envelopes.—*Brit. Med. Jour.*

Kidney Failure in Pregnancy.

EWING MARSHALL, M.D., the writer thinks that there is much confusion on the subject of kidney pathology; and believes that the initial step is a failure of assimilation; and that the changes in the kidney are secondary, and resultant. With this pre-organic period of kidney failure, or some latent form of kidney lesion with the kidney laboring, then pregnancy will give the kidney more work than it can accomplish, and then we have the symptoms of failure.

Treatment:—First, strive to restore equilibrium so promptly as to prevent organic changes in the kidney.

Second, temporize with the kidney after it is organically involved by giving it the least possible work by dieting, and by keeping the skin, the bowels, and the lungs at the highest possible eliminative potency.

Treatment of kidney failure in pregnancy is to prevent the serious climax of kidney failure, which is eclampsia; second, to treat the latter.

When eclampsia occurs the uterus should be at once emptied after which morphia, chloral, chloroform, etc., may be used to quiet the reflexes.—*Post. Grad.*

Vaginal Colpotomy: its Advantages and Limitations.

Dr. T. HENRY WILSON read a paper on this subject. Having described the method of anterior colpotomy, he pointed out the facility with which the adnexa might be drawn down and examined, adhesions of the ovaries separated, and tubes and ovaries removed, or, if found healthy replaced. Small subperitoneal myomata, if pedunculated, might be ligated, or, if sessile, incised, removed, and the peritoneum closed over. Small ovarian and parovarian cystomata might likewise be easily treated, or if too large the contents might first be evacuated, the pedicle tied, and the

cyst removed. He expressed disapproval of the operation of vaginal fixation for retroversion, except in cases past the child-bearing period, or for the control of hæmorrhage impossible by other means. He then dwelt specially on the treatment of pyosalpinx by this method, and laid stress upon the usual site of rupture of the pus sac when separating adhesions—namely, the posterior surface, which was the most unfavourable situation in operating by coliotomy but favourable when by vaginal colpotomy. He strongly advocated removal of the uterus in severe cases of pyosalpinx with dense adhesions of long standing. Having described the operation of posterior colpotomy, he discussed the question of pelvic hæmatocœle and pelvic abscess, pointing out the great advantage this method presented for efficient drainage. Densely-adherent ovaries deeply situated in DOUGLAS' pouch he regarded as suitable for the posterior operation, but he deprecated treatment of ruptured tubal pregnancy by the vaginal method. Two difficulties in colpotomy were emphasised, namely, rendering the vagina aseptic and reaching the peritoneum. He also drew attention to the ever-present danger of wounding the ureters. He compared the separation of adhesions by SCHULTZ's method and vaginal colpotomy, with the danger of concealed hæmorrhage in the former, and expressed his preference for the latter method as being more under control. He insisted strongly that no one should undertake vaginal colpotomy who was not prepared to open the abdomen if found necessary, as there was always present the danger of uncontrollable hæmorrhage, and the possibility of being unable to complete the operation from below. He then mentioned certain cases not suited to this operation, as large dermoid tumours, deformity of the pelvis, rendering the operation very difficult; large ovarian tumours and advanced ectopic gestation. He claimed as advantages the absence of risk of ventral hernia, less shock, absence of the distressing thrust so common even after exploratory abdominal incision, and more speedy convalescence. In summing up he thought the question to ask oneself was, Can this be done by the vagina?—*Brit. Med. Jour.*

Some Common Mistakes in Gynecological Diagnosis

Dr. J. C. WEBSTER says symptomatology and clinical history are determinate and often cannot be distinctly correlated with various lesions. Other than local factors must be taken into account. Of chief importance among these is the neuropathic state. A neurotic condition may be developed from causes foreign to the pelvis, and this may manifest itself in intense pain referred by the patient to the pelvic lesion. In another set the symptoms of pelvic pain are developed as one of the phenomena of a neuropathic state, there being no local lesion of any kind.

Mrs. H. complained of pain in the bladder and was treated for cystitis without success. Cystoscopic examination showed a normal mucosa except a congestion of the right ureteric orifice. Palpation of the loins revealed an enlargement on the right side. Bacteriological examination of the urine showed the tubercle bacilli. Operation resulted in the removal of a tuberculous kidney.

Another case is cited in which painful micturition was an early symptom of locomotor ataxia. A chronic parametric abscess had given symptoms of cystitis. A Russian lady-doctor was treated for cystitis for some time without success. Examination showed a small fibroid on the anterior uterine wall near the attachment of the bladder. Cancer of the rectum gave symptoms referable to the coccyx which was excised under the belief that coccygodynia was the trouble. Papillomata of the bladder may give rise to hæmaturia, which may often suggest the kidney as the source.—*Post Grad.*

PHYSIOLOGY, PATHOLOGY AND BACTERIOLOGY.

Metabolism in Total Resection of the Stomach.

DR. HOFFMANN, the author, has investigated the metabolism in SCHLATTER's well-known case of total resection of the stomach. Six and a half months after the operation the patient had gained 5.4 kilog. (9 lbs.) in weight. It was found that the amount of nitrogen present in the stools varied within normal limits, but during the six days a complete nitrogenous balance was not obtained as occurs in health. There was a retention of 0.1 to 1.4 g. ($\frac{1}{4}$ to 21 grns.) of nitrogen. This retention is known to occur in convalescence from acute illnesses, etc. There is no increase in weight during the first period of observation. A month and a half later a further investigation was made with a more varied diet, and here the absence of the stomach seemed of no importance. A nitrogenous balance could now be established, showing that the regeneration of the blood was so far complete that there was no longer any need of retention of nitrogen. The retention of phosphorus was also marked. HOFFMANN found that fatty matters were satisfactorily dealt with, so that of 8.5 g. (127 grns.) taken only 4.64 g. (70 grns.) were excreted. He adds that this shows how incorrect it is to treat patients suffering from chronic stomach disorders with as little food as possible. The author has also investigated the question of the action of hydrochloric acid upon putrefactive processes, and he concludes that the absence of the acid in this case was without influence upon these putrefactive processes in the alimentary canal. He goes so far as to add that the administration of hydrochloric acid as a disinfectant of the intestinal contents is useless. As regards the quantity of chlorides in the urine, there was no decrease after the chief meal in this case. This confirms the current view that the diminution of the chlorides in the urine after a meal is due to the hydrochloric acid excreted by the stomach. The absolute acidity of the urine was higher in this case than in ordinary individuals. The retention of sodic chloride was striking, without there being any increase in the body weight. There was no relationship between the excretion of chlorides and the acidity of the urine in the different periods of the day. The urine was examined for the presence of pepsin, but no trace was found.—*Post Grad.*

Telegony.

THIS term was proposed by Professor WEISMANN to denote the cases where the female is so far influenced by the first sire to which she bears offspring that the subsequent offsprings to other sires presents some of the characteristics or peculiarities of the first. Early in the century Lord MORTON bred from a chestnut mare a quagga hybrid, and the mare afterward produced to a black Arabian horse a filly and a colt marked like the hybrid. In the *Scottish Medical and Surgical Journal*, Dr. J. C. EWART takes up the subject from the view-point of his own original researches. In 1895 Professor EWART formed a small stud and commenced various crossing experiments between horses and zebras. He now has given zebra mare hybrids, and the dam of a last year hybrid has recently produced to an Arab horse a foal presenting numerous zebra-like stripes over the rump and loins. He enumerates the explanations of this phenomenon that have been suggested by Sir EVERARD HOME, HERBERT SPENCER and WEISMANN, all of which he thinks are highly improbable.—*Jour. Amer. Med. Assoc.*

Alterations in the Shape of the Trachea.

SIMMONDS, prosector at the large hospital at Hamburg, has been making a study of casts of tracheas. He found numerous constrictions, dilations and angulations; scoliosis was noted in one-fourth of all the cases. Constrictions pro-

duced by the pressure of aneurysms, tumors and latent goiters were frequent, also a groove which he attributes to the pressure of the arteria anonyma. The walls were frequently found ossified and flattened in elderly persons, for which he suggests the descriptive name of "senile sabreath trachea." Universal dilation was only noted in one case, probably congenital, but partial ectasia was common, almost invariably in the middle section of the rear wall, in elderly persons, accompanied with atrophy of the wall.—*Jour. Amer. Med. Assoc.*

Etiology of Syphilis.

VAN NISSENN, of Wiesbaden, in an exhaustive article embodying the result of much original work states that: (1) Syphilis is a chronic infectious disease of the blood, the contagium reaching the blood from without by means of the lymphatic vessels, and in turn is brought to the other tissues of the body from the blood by means of the lymphatics. (2) The contagium of syphilis in every case and in every stage of the disease from the moment of its entrance into the blood is capable of microscopical demonstration by staining and by cultivation. In many cases it can be found in the urine and milk; the semen, the sputum, the sweat, and the excrement may also contain the germs of the disease. (3) The contagium is not found in cases other than syphilis, or in diseases complicated with it. (4) The virus of syphilis is a pleomorphic form of bacillus which stands in close relation to the higher organized fungi and the actinomyces of the class *Dematiaceae* and *Cladospirium*. (5) The detection of the etiological factor of syphilis in the blood is an absolutely sure criterion for the diagnosis of syphilis and is therefore of the highest diagnostic importance in disputed cases requiring differentiation. (6) In all its stages syphilis is inheritable and communicable. This applies also to rabbits which are capable of being infected experimentally with syphilis. (7) With the therapeutic means known up to this time syphilis is absolutely incurable. Relative healing merely denotes a latency of the disease. It is therefore of the greatest importance to mankind that a really curative agent be discovered.—*Inter. National Mag.*

Congenital Tumours.

SCHMORL exhibited, at a recent meeting of the Gynaecological Society of Dresden, three rare specimens of congenital tumour. The first was a teratoma attached to the pelvic extremity of the fetus by a cystic projection passing between the rectum and the coccyx. It was of the size of an infant's head, and was the cause of delay in labor. The second was a growth from the right pleural cavity. It was of the size of a pigeon's egg, of firm consistence, and of a brownish red colour, and it was attached by a broad base to the vertebral column just above the diaphragm. It was not attached to the right lung, but it consisted of an alveolar structure very closely resembling that of the lung. It was regarded as an accessory and imperfectly formed pulmonary lobe. The third specimen was a congenital tumour of the stomach, which had been removed from an infant which had died from pneumonia when eight days old. It was of the size of a bean, and was situated in the greater curvature, about 3 cm. distant from the pylorus. It lay chiefly in the submucosa and muscularis, and had a gelatinous appearance on section. Microscopically it was an adenoma.—*Brit. Med. Jour.*

Anti-Tetanic Properties of the Central Nervous System.

WASSERMANN and Takaki find that the brain and spinal cord of man, guinea-pig, rabbit, pigeon, and horse exert an anti-toxic action towards the tetanus toxin. One c.c. of brain-emulsion was found to neutralize ten times the fatal dose of tetanus toxin in mice even when injected six hours after the toxin. The spinal cord acted less powerfully than the brain, while the liver and other organs were without action.—*Treatment.*

PUBLIC AND DOMESTIC HYGIENE AND JURISPRUDENCE.

Disinfection of Rooms.

NOVY and WAITE conclude a paper upon the above subject with the following general directions (1) All cracks or openings in the plaster or in the floor or about the door and windows should be caulked tight with cotton or with strips of cloth (2) The linen, quilts, blankets, carpets, etc., should be stretched out on a line in order to expose as much surface to the disinfectant as possible. They should not be thrown into a heap Books should be suspended by their covers, so that the pages will fall open and be freely exposed. (3) The walls and floor of the room and the articles contained in it should be thoroughly sprayed with water. If masses of matter or sputum are dried down on the floor, they should be soaked with water and loosened No vessel of water should, however, be allowed to remain in the room (4) One hundred and fifty centimetres (five ounces) of the commercial forty per cent solution of formalin for each one thousand cubic feet of space should be placed in the distilling apparatus and be as rapidly distilled as possible. The keyhole and spaces about the door should then be packed with cotton or cloth (5) The room thus treated should remain closed at least ten hours If there is much leakage of gas into the surrounding rooms, a second or third injection of formaldehyde at intervals of two or three hours should be made — *N. Y. Med. Rec*

Production of Immunity.

WHATEVER method be used, the following points are now almost proved (1) the immunizing substances are in all probability of a proteid nature, (2) sterilized cultures or filtrates deprived of their specific poisonous properties may have a marked power of producing immunity, (3) an inoculated animal is for a short time after inoculation more susceptible to an attack of the specific disease, but as soon as this stage of susceptibility has been passed the resistance is increased, (4) whatever specific bacteria are used, either in the virulent or the attenuated form, the aim is to produce a mild attack of the disease, as a result of which the animal is immune (5) the period required for the acquisition of immunity is in this case much greater than when antitoxin blood serum is used, in which latter case a protective influence is recognized almost immediately, or at any rate, in the course of a few hours, (6) it is found, however, that the immunity so produced (the passive immunity of Ehrlich) is more transient than that obtained by inoculation with microorganisms or their products, (7) the blood serum of naturally immune animals has not yet been proved capable of producing immunity when injected into susceptible animals TREVES' *"System of Surgery"*

Common Errors of General Practitioners in Dealing with Cases of Pulmonary Tuberculosis.

DR FREDERICK I. KNIGHT of Boston, referred to certain common errors which he thought might be diminished if his remarks were indorsed by the members of the association in such a way as to give them the authority needed to influence the general profession. The errors to which he especially called attention were (1) Failure to make an early diagnosis, which is now easy since the discovery of the tubercle bacillus (2) Failure to admit the gravity of the situation the moment it is discovered, and to put the patient at once in the best possible condition for recovery NIMMEYER used to say that the danger of a consumptive patient was "that he became tuberculous." In the light of modern pathology Dr KNIGHT would say that the danger of a tuberculous patient was that he became consump-

tive, *to*, the subject of secondary infection. There was often failure also to impress the patient with the gravity of the situation sufficiently to secure his thorough co-operation in the effort for his recovery. (3) Temporizing, giving nauseating medicines and too much alcohol, and prescribing exercises, etc., which only hasten the decline. (4) Sending patients away from home who have only a few months or weeks to live, or who have not sufficient money to live properly away from home long enough to do them any good, also exercising insufficient care in the selection of a residence for those who would probably be benefited by a change. (5) Insufficient professional supervision of patients, who always require constant watchfulness, whether they remain at home or go to some climatic resort — *N. Y. Med. Rec*

Syphilis as a Cause of Abortion.

DR J. A. QUIMET concludes (1) Syphilis is a powerful cause of abortion, the abortion being due to a lesion of the fetus itself or its appendages (2) It occurs mainly about the seventh month The father, if alone syphilitic, can transmit the syphilis to the product of conception The latter is more liable to occur the nearer the moment of conception is to the beginning of syphilis (3) The mother may give birth to a syphilitic child, while remaining free from syphilis (4) When the father and mother are both syphilitic the child rarely escapes infection (5) The mother, if syphilitic before pregnancy, is more liable to give birth to a healthy child the more ancient the syphilis (6) The nearer the syphilis approaches the termination of pregnancy, the greater chance the child has to escape infection (7) The child born of a syphilitic mother may come into the world presenting lesions manifestly syphilitic, or be born apparently healthy and become syphilitic only after some months or even years Syphilis imparts no particular characteristic to the course of confinement Mercurial treatment should be instituted at the beginning of pregnancy — *N. Y. Med. Rec*

Legal Restraint of Marriages.

RUSSELL recently presented "A Plea for Posterity," before the Washington County (Pa.) Medical Society, a paper in which he cites statistics of many present sociologic conditions and makes a plea for legal restraint of marriage among certain classes He says "Some would deny the right of existence, claiming that this right has been forfeited by the inferior mental, moral, or physical status of himself or his ancestors As the existing order of things involves the visiting of the father's sins upon the children, even the most conservative must admit that the defective has no right either natural, moral, or legal, to produce a posterity cursed with his affliction to be a danger and a burden to you, posterity and mine There are, however, other fountains feeding this stream of corruption, and we can never hope to stay the tide until they are controlled through heredity itself, by denying to the defective the right to propagate his tainted species These fountains are alcoholism, syphilis, tuberculosis, epilepsy, insanity, and gonorrhea." He then considers these several "fountains" in detail and concludes with a bill prepared by him for the Legislature of Pennsylvania, with a view to securing such State laws as will prevent the issuing of a marriage license to any person "contemplating marriage unless he or she shall have received from the persons so appointed a certificate setting forth that such applicants are free from the following diseases, any of which shall be deemed sufficient cause for refusing a license Syphilis, gonorrhea, dipsomania, hereditary insanity, true insanity, or insanity resulting from vice, epilepsy, hereditary consumption or tuberculosis" He says that the State of Texas already prohibits the marriage of epileptics, Massachusetts, the epileptic, alcoholic and syphilitic, while Ohio has a similar law to the one proposed, and the same bill has been introduced in the Maryland Legislature — *Jour. Amer. Med. Assoc.*

THERAPEUTICS AND PHARMACOLOGY.**Malarial Disease Prevented by Small Doses of Quinine.**

LAVERAN reviews the reports of many medical officers in charge of the health of bodies of European and American men exposed to severe malarial influences. His conclusion is that quinine usually proves very potent in preventing or at least mitigating malarial disease, even in very unhealthy localities. Against its use the objection has been made that daily administration of this drug induces attacks of indigestion, and that quinine becomes less potent in a given case if administered constantly, the system becoming habituated to it. Yet these objections are not sound. A dose of from one-fifth to three-tenths of a gram a day can be employed for months with impunity. Quinine destroys the causative microbes by its power as a parasiticide. The microbes of paludism that chance to get into the blood of a person who has been treated preliminarily by the small preventive doses, find it a medium wholly or quite unfavorable to their development. At the most, they develop only with difficulty. The daily dose should not exceed three-fifths of a gram nor be less than a seventh of a gram. Some prefer a dose of one gram thrice weekly. To procure a rapid absorption, the hydrochloride is preferable to the sulphate, and is better supported. The best time to take quinine is at meal-times. The best way is to dissolve it in wine, although cachets or pills suffice. If added to coffee, that precipitates a portion of the quinine.—*N. Y. Med. Jour.*

Peculiar Susceptibility of women to the Toxic Action of Sulphonal.

POLLITZ relates the case of a woman who was treated very successfully for a puerperal mental affection with sulphonal given to the amount of twenty-two and afterward fifteen grains daily for more than a year, with frequent interruptions of the treatment for weeks at a time. Finally symptoms of sulphonal poisoning appeared—deep-red coloration of the urine and diminution in the amount of that secretion, obstinate constipation, and loss of appetite. The case ended fatally, but it is remarkable that periods of notable improvement in the woman's condition preceded her death. At the post-mortem examination there was found extensive disease of the secretory epithelia of the urinary tubules. POLLITZ calls attention to the fact that the recorded cases of sulphonal poisoning have been in women for the most part. Among twenty-one cases, SCHULZ found that twenty were in women, and all observers have found that the victims of sulphonal poisoning were anæmic to a certain degree. The inference seems reasonable, POLLITZ thinks, that certain conditions of the blood, such as chlorosis, have a direct connection with the supervention of toxic phenomena under the use of sulphonal.—*N. Y. Med. Jour.*

Strychnine in Alcoholism.

FEDEROFF who has employed strychnine in the treatment of twelve cases of alcoholism has noted the following results: (1) The catarrhal symptoms subside more rapidly than they do in the cases in which the patient is deprived of alcohol and submitted to a strict regimen. (2) The neurasthenic attacks are favourably influenced by the strychnine, and the insomnia, as far as it is dependent upon nervous causes, soon disappears, the strychnine acting better in this respect than the usual hypnotics. Sleep becomes normal at the end of five or six days. (3) The senseless anger and the irritability which characterize alcoholics progressively subside. (4) The depression of spirits gives way to a more tranquil state of mind and the patients become courageous. (5) Other morbid symptoms, particularly the migraine, also pass away. (6) Unfortunately, the chief symptom,

the craving for drink, is not influenced to any marked degree. "So that," says the writer, "though one must acknowledge the good effect of strychnine upon the nervous phenomena of alcoholism, it cannot be spoken of as a specific for this disease."—*Med. News.*

To Cure Itch in Two Hours.

EMPLOY fresh calcium sulfuret made as follows:—

Sulfur (flour) ...	3 ozs.
Quicklime ...	6 ozs.
Water ...	2 pts.

Boil together till combined, then allow to cool and settle. Decant and preserve in hermetically sealed bottles.

Rub patient all over with soft soap for half an hour, then place in a tepid water bath for another half-hour. Next rub over with the solution and allow it to dry on the skin for a quarter of an hour. Complete by washing in the bath.—*Med. Age.*

Correspondence.

A PROTEST AGAINST PASTEURISM.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Critics hostile to Pasteurian methods have two advantages: they remind bacteriological doctors that there still remains much to do to dissipate the doubts which persist, not only among a portion of the public ignorant of scientific things, but even in the minds of some doctors who have remained out of the great medical revolution performed by the discoveries of Pasteur; moreover, they attract the attention of the public to the progressive development of these methods, to the genuineness of the results, and to the advantages which humanity derives from them.

A volume would be necessary to pass in review the modern applications of Pasteurism to medical science and surgery. This letter being inspired by a critic on the anti-rabid treatment, will have no other object than to show how the proofs of the efficiency of this treatment are simple, clear, and irrefutable.

The duration of the treatment is from 14 to 16 days, and experience has shown that another twelve days was necessary after the last inoculation in order that immunity be established. It follows that a duration of 26 days is necessary for the treatment to have any effect.

This said, let us take a healthy animal and subject it to the anti-rabid treatment. If 26 days after we inoculate rabies in its brain, a place where the inoculation is surely and rapidly deadly, the disease will not show itself, the animal will not be troubled by the strongest rabid virus. On the contrary, if we inoculate the brains of dogs not having followed this treatment, they will catch the mortal rabies.

The inoculation of rabies by a bite in persons or animals takes place in any part of the skin. The virus grows along the nerves and reaches the brain on an average of 40 to 60 days. It is proved that it is only when the virus has reached the brain that the disease displays itself.

It is thanks to this long period of incubation that Pasteur has been able to find the anti-rabid treatment. If they make a rabid animal bite a healthy animal, and if then they subject the latter to the anti-rabid treatment, it will be immunized at the end of 26 days, and the effect of the penetration of the rabid virus by the bite before the treatment will be neutralized. This experiment, multiplied on animals before applying the treatment to man is successful 99 times out of a 100.

Long experience of the effect of the treatment in the same conditions on man shows its efficacy in proportions as marvellous as on laboratory animals. There are some failures, but their number is remarkably small, and they are noticed almost exclusively among people who began the treatment a long time after the bite, or whose bites, by their seat, their depth, or their multiplicity, belong to the category of those in which hydrophobia shows itself usually in less than 26 days among person not treated.

It is sufficient, in order to convince the most sceptical to place before them the figures indicating the results of the treatment.

At the Pasteur Institute of Paris, from its establishment up to 1897, 20,166 persons have undergone the treatment. Of this total number 96 contracted hydrophobia, i. e. 0.46 per cent.

Surgeon-General THORNTON reckons that many people are treated without having been bitten by really rabid animals. Let us see then the results in the cases where the animal that bit was surely afflicted with rabies.

Of the 20,166 cases, 2,872 persons have been proved experimentally to have been bitten by rabid dogs. Now, among these 2,872 persons treated after having been bitten by dogs undisputably rabid, 20 only, i. e., 0.69 per cent. got hydrophobia.

These figures, the authenticity of which everybody can verify, are the best argument in favour of the anti-rabid system.

In the Pasteur Institutes which have multiplied on the surface of the globe, the results are much the same as in Paris. Mortality is greater in those institutes which receive strangers coming from a long distance.

For instance, at the Saigon Institute, of 421 persons treated since 1891, there have been 10 cases of hydrophobia. But it is to be noted that six of those unsuccessful cases took place among strangers who had come from very far and who had begun the treatment 11, 14, 19, 20, 30, and 51 days after the bite.

It would be difficult to quote a more convincing proof of the efficacy of the Pasteur treatment than this difference of mortality between persons who can follow the treatment a short time after they have been bitten, and those who have a long journey to undertake in order to go to the Institute.

At Saigon, of 154 persons who had come from distant countries and who had begun the treatment from 11 to 51 days after the bite, six got hydrophobia, whereas of 267 persons coming from the colony, there were only four cases. After what I have just said I think it useless to refute the extraordinary assertion of Dr. THORNTON that the treatment gives hydrophobia. Who will believe that a treatment likely to give hydrophobia gives it only once in a hundred times? It would be necessary in that case to admit then that it is the bite of the rabid animal which preserves man against the treatment which they make him follow afterwards.

There were during the first years of the application of the treatment, scientific men like Professor POTAIN who have, in good faith, relying on some unsuccessful cases like that of RABOL mentioned by Dr. THORNTON, denied the efficacy of the treatment. One after the other have recognized, in the long run, the falseness of the theory which attributed these exceptional cases of hydrophobia, not to the bite of the rabid dog, but to the treatment itself and not a voice rises nowadays in France against the inoculations made at the Pasteur Institute. The mortality by hydrophobia was, in France, before the treatment, from 25 to 30 per cent. among persons bitten by suspicious dogs. This mortality is the same among the few people (a very small number of them) who do not follow the Pasteurian system; the mortality is less than one per cent. among those who are treated.

In every country where a Pasteur Institute is established, one sees the number of known cases of bites by rabid dogs increase immediately. The reason is simply

because, in the absence of any establishment where cases are treated, 99-100ths of persons bitten remain unknown.

For an instance let us take India. Nobody has an idea of the tremendous number of inhabitants who die yearly of hydrophobia in that country. One can have an idea of the number of rabid bites in calculating them according to that which takes place among Europeans living in India. The latter have furnished during the year 1897, 33 clients to the Pasteur Institute in Paris. In admitting that the Indian population is 500 times greater than the European population (this figure has been given to me as a minimum by a high official of the Indian Civil Service) and if the cases of bites by rabid animals take place among them in the same proportion we get, by multiplying 33 by 500, 165,000 natives bitten. It is a certain fact that cases of human hydrophobia take place yearly all over British India and that these cases escape entirely from the statistics.

Yours &c., A DISCIPLE OF PASTEUR.

—:—

RAILWAY MEDICAL OFFICERS AND THEIR STATUS.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Appropriate though the remarks on page 426 of your last issue, the grievance can only be remedied by legislation as all railways, state or otherwise, work under P. W. D. regulations, which lay down grades as —

(a). *Officers*—The Chief Engineer down to Assistant Engineer; the Heads of the Traffic; Loco; Audit, Accounts and Examiner Departments; the Chief Medical Officer and his personal professional Assistants, otherwise known as Medical Officers

(4) *Upper Subordinates*.—Overseers, Foremen, Inspectors of works &, whether travelling or stationary, and all employees receiving over Rs 100 per mensem, in which list are included Assistant Surgeons in medical charge of Districts or workshops. To this class are relegated Military Assistant Surgeons transferred to civil medical charge of railway districts

(c). *Subordinates*.—Clerks and Office establishment, Hospital Assistants and all employees receiving over Rs 25 and under Rs 100 per mensem

(d). *Lower Subordinates*.—Compounders, drivers, Jacks, Apprentices, and every one drawing less than Rs 25 and over Rs 8 per mensem.

(e). *Menial Establishment*.—All posts below Rs 8 per mensem.

At one time the medical help of classes b and c was exclusively recruited from Hindus and Mahomedans of the Civil Branches of the Indian Subordinate Medical Department, and the Engineer establishment was borrowed from the Public Works Department; but what with congestion of the fields for engineering and medical practice by a rapid increase in trained competitors, and the desire for economy and a more ductile class of men who would not have the right of appeal to Government, the mode of working remained the same; but the choice of medical help was left to the sole discretion of the Construction Railway Companies' Chief Medical Officer, who preferred to employ non-Government hands; who would be required

to pay their own joining expenses and, some two or three months after joining, asked to sign an "agreement" in which the Railway Company bound itself to NOTHING beyond a "months notice terminate contract" while the Assistant (?) Surgeon, who is clearly given to understand that he is to attend Railway employees only,—not Contractors or their coolies &c.,—and can use his spare time as he likes in private practice, or otherwise, is required to express himself willing to submit to being fined by the District Engineer for neglect of duty, &c.

If he refuses to sign this agreement (?) of which no mention is made in his "letter of appointment" he must tender his resignation, serve his notice out and vacating railway quarters patiently wait, for perhaps a year or more as I have done, without yet being paid, the sweet convenience of the Audit Department for settlement of monetary dues.

If he loses patience at the unwarrantable delay and asks ever so politely for early settlement, the fact of his having long since left their employ is ignored and he is turned out of the office with something like "you are too—d impertinent for a b—y subordinate," yelled at him, and if he seeks relief through the Courts the railway telegraph is set in motion to boycott him and under the plea of "privilege" assail him with all sorts of imaginary offences.

Before he signs this agreement form A he is treated like a gentleman, consulted on every sanitary point, paid for attending contractors and their men, and the clerks, syces &c, have to wait on him at the railway dispensary, but form A once signed, 'Lo! Presto!' He becomes a b—y subordinate, who, if his C. M. O. is not a strong man, is at the beck and call, unpaid, of even the officers (?) private menials or contractors' coolies who insist on his coming to their godowns to attend to trifling ailments. If he disobey such a call or stand on dignity or commit the most trivial offence he is heavily fined, and if he appeal against the fine, he is impertinent or insubordinate.

With the completion of construction and establishment of "open line" two or three medical districts are condensed into one and the majority of the "construction men" are discharged. With open line also this superciliousness goes on until the Government takes over charge from the working Company, whose officers and employees it is compelled to maintain till their time expires or they otherwise retire.

When the Government placed the State railways under the control of the Inspectors General of Civil Hospitals, and began to man them with Military and Civil Assistant Surgeons who do not belong to the P. W. D., some special provision should have been made for the proper grading of Warrant and other officers, who, unlike the P. W. D., have the right of rising to commissions.

These are questions that the Indian Medical Association could well handle, and to support the accuracy of my statements I have a huge mass of documentary and reliable evidence that I would be glad to place at your disposal, with a view to ameliorating the condition of those unfortunates who are compelled to suffer the indignities and superciliousness I refused to submit to.

Yours &c., RAILWAY SURGEON.

THE COMING EUROPEAN CONFERENCE AT ALLAHABAD.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—The following is from the *Eastern Guardian of Madras* :—

"If we are to reckon red-letter days of our Community or Associations they can be counted on less than the fingers of one hand, being so few and divided by wide intervals of time. For the rest, deluded by false hopes, encouraged by promises without even a resemblance to the proverbial pie crust, which is remembered at least to be broken, they have followed these from afar till, mirage like, they have faded from view, leaving the desolation around them more hopeless and realistic than before. Toiling on from year to year, in sanguine anticipation of that better time, to which we all look forward with such yearning desire, they have wrought for their Queen and country, accepting their yoke meekly like draught cattle, unresistingly and unmurmuringly, awaiting in loyal faith the advent of that day, when their rulers, seeing the value of their work, and their indispensable usefulness as departmental chiefs, at least, if nothing more valuable and more eligible, will awake to a sense of propriety and gratitude to reward their zeal and efficiency. Their endurance has been bootless, their recompense broken promises, their patience has been in vain. Hopes deferred, and deferred indefinitely, caused many, sick at heart, to nurse a depression ending in retirement from office with all possible celerity or to adopt an exile in England where justice is done to all indiscriminately. Without leaders, without personal influence, or Parliamentary interest, they have, against their will, been silent, when they have seen younger and less capable imported men put over their heads, usurping praises and prizes which natural justice would demand as their own right, a right, truth and justice and fair dealing have already repeatedly pronounced to be theirs indisputably, but which a Government, that professes to be 'all things to all men,' under pressure, to serve party purposes and please friends in high places, here and at home denied them. Few, indeed, have been our countrymen's so-called letter days in India. Anglo-Indians and domicile Europeans have become a drug in the labor market of India, and answering the inexorable law of supply and demand, they must bide their time, till some unforeseen political tide shall flow and their services be needed. At present, we have the native attitude at our own rates, which we can lower at will, what care we for Anglo-Indians, Europeans or Eurasians? remarks a thrifty paternally beneficent Government. It is only when hard knocks are being dealt out, and deadly weapons are brought into play; only when Baboodom gracefully retires into sulkiness—and very close seclusion, indeed—that we need feel concerned about enticing back Anglo-Indians. We know, like the poor, they are always with us, and in their worst moods a few kind and inspiring words will easily arouse their enthusiasm, and we may whistle them back at our will. While, the more favored class sucks its sustenance through a pen at its office desk, picking its plums of office with a punkah overhead and a somnolent oodle at the end of a string for diversion, as an exercise of that commendable virtue *patience*, Anglo-Indians must bear the heat and burden of the day. While the native is discuss-

ing his *jelabees*, Anglo-Indians may be safely entrusted with field operations to risk and to lose their lives under a patriotic inspiration of duty to their father-land.

No ruler of India has, or cared to, understand the proper control of human passion, or grasped that problem which deals with the right government of men, or how to divert currents of disaffection arising from disappointed ambition, into resourceful streams of sympathy, of loyal confidence, of devoted attachment; or if he has, has ever enunciated this. India, therefore, is not in such a condition of security as we and her best friends would wish to see her. Our good representatives and leaders in conclave at Allahabad when they meet in Conference, should decline to be silenced by a false fear of offending Government, which risk they never will incur by a constitutional representation of grievances. Our rulers will not object to candour, if it be legitimate, or to expressions of caution, if they are discreet. Our delegates should do their duty fearlessly, yet temperately. They will have before them an opening that, if rightly followed up, may lead to an annual Congress which ere long may prove itself a valuable auxiliary to a home agency in London. We urge upon our delegates to insist upon their rights, not as favours, not as concessions, or privileges, but as claims upon a Government for whom our fathers have fought and bled. India was being wrested from British dominion when Anglo-Indians, in non-combatant communities, stepped boldly forward, threw themselves into the breach and helped our brave soldiers, shoulder to shoulder, to recover a possession that England felt was slowly yet surely slipping through her fingers and upon which her grasp had been most materially loosened. If we avail ourselves of what this Conference will indubitably offer us—an opportunity for amalgamating our forces, and of meeting annually for purposes of self-protection, the self-preservation of our rights—a great and valuable work will be done and our labours will result in a well deserved triumph. We are perfectly confident in our Madras delegates as they are representative men in the sense of ably dividing this work between them. It is for them to feel that they bear on their shoulders, with the other delegates, the responsibilities of three important Presidencies, whose graver interests up to this juncture were practically ignored and treated as mythical, interests which they have the responsibility imposed upon them of crystallising into national claims and rights to be granted in the Government of India."

Yours &c., ANGLO-INDIAN.

—:O:—

THE RISLEY PLAGUE IN CALCUTTA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—In your issue of November 1st, page 379, you seem to doubt that true Plague has been in Calcutta at all and dub it "Risley Plague" on the false, self-laid-down, criteria that it has become neither contagious or epidemic. Two facts will, I feel sure, correct your misunderstanding and enlighten your ignorance regarding this matter, and as it is an error into which previous authors have fallen, I may be excused for correcting it. "To make use of so uncertain and variable an attribute as the contagiousness, or the degree of contagiousness, of

an existing fever, as a diagnostic mark of the plague—as some nosologists and other medical writers have done—is obviously illogical and must inevitably serve to mislead. In the case of the malignant Danubian fevers, several of the Russian medical officers denied their pestilential character, on the sole ground that no distinct proofs of “contagion par attouchement” had been observed, while they admitted that all the symptomatic characters of the true plague were present. Many similar instances might be cited where this fallacious test has been employed. Indeed, most of the absurd errors in the history of the disease during the present and last century, may be traced to this very source.”—(Milroy).

As a confirmatory fact, I refer you to the Transactions of the Bombay Medical and Physical Society for March, where I elucidated and enunciated “the want-of fresh air theory” of plague; and showed several places where real plague occurred, but was prevented from spreading by removal of tiles, and thus letting in its natural enemies, fresh air and sun-light; and I could adduce numerous confirmatory proofs. Now, Sir, it is conceivable that Mr. RISLEY and Drs. BANNERMAN, DYSON, CHARLES, and the able I. M. S. men in Calcutta are fools; and that you are the paragon of wisdom as regards what constitutes or does not constitute plague;—but it is difficult to believe; nor can I think that these gentlemen and others are banded together to fabricate plague, even a “Risley Plague; or foist it on Calcutta.

Having had the unique pleasure of acting as plague preceptor to Drs. BANNERMAN and DYSON I think they, from experience, know plague when they see it; and HAFKINE'S finding plague bacilli only confirmed their diagnosis, up to which time they were unwilling to pronounce publicly that plague had appeared, and his investigations were only confirmatory of the truth of their conclusions. Drs. BANNERMAN and DYSON require no championing at my hands and it is only to let you see eye to eye with them and me, that I write this note, which may lead you to remove an unmerited slur on upright and reliable investigators; and they have no knowledge of my writing it.

At page 509 of your issue for June 16th, 1898, there is a case of true plague reported by Dr. PANIOTY in and from Calcutta and from the clinical symptoms and after 18 years medical experience, and two years special daily plague experience, I am unable to place it nosologically anywhere but under Plague.

If you think it was not plague how do you diagnose it?

It is therefore an epidemic logical heresy—I can call it nothing else—to hold that because such a faithfully clinical type of disease is not epidemic and contagious that it is not Plague.

I can reconcile Dr. PANIOTY'S concluding remarks with what we know now of Plague and resolve the apparent contradiction. The disease is conditioned, and is only infectious where there is want-of-fresh air; due to deficiency of it, filth or overcrowding. I have already adverted to its absolutely non-contagiousness in well ventilated, sanitary, plague hospitals (vide General Gatacre's Report on Bombay Plague and Transactions Bombay Medical and Physical Society); and the very first ques-

tion Prof. KOCH asked me at Parel in 1897 was “Is plague infectious?” and I answered then as I do now, yes and no !!! All these infectious diseases are conditioned, and what the factors for plague infection are, I hope the above will convince any thinking man; and I am engaged in elaborating this want-of-fresh-air theory still further with historical proofs &c.

It is a mistake to point to the small mortality in Calcutta as a proof that there was no plague, as it is very well known about half the people ran away from the city; and that half composed of those chiefly who believe plague to be due to fate, and therefore they had to bolt into the jungles and elsewhere in pursuit of their *nash* !!!

That plague did not become epidemic in Calcutta was partly due to this large exodus of susceptible people, thereby diminishing the normal overcrowding; and to the fact that every case was seen early, resolutely dealt with, and the seed in a great measure kept out of the suitable soil. It is but poor recompense to those who succeeded hitherto in this huge and almost impossible task, to detract and hurl jibes at them in the medical and lay press.

Yours, &c., GEO. S. THOMSON.

SATARA,

Capt., I.M.S.

THE SO-CALLED PLAGUE MANUFACTURED TO ORDER, IN CALCUTTA—NOT MADE IN GERMANY.

TO THE EDITOR “INDIAN MEDICAL RECORD.”

SIR,—The annexed is from *Indian Engineering* and serves to support your views:—“That the Hindoo and Mahomedan portion of our City Fathers, who are proverbially timid and deficient in moral courage, so admirably depicted by the late Sir SYED AHMED, should turn pale at the prospect of standing face to face with such an awful visitation of Providence is ‘understandable,’ but that the Executive of the Corporation should have been scared out of their proprietries and carried along with them the European element, men of light and leading as well, is a sight deplorable to contemplate. Newspapers meanwhile were not idle. Two out of the three Anglo-Indian journals were very busy at the forge—the clang of their hammers could be heard at a distance, long before the solitary “imported case” was noticed here. The native papers behaved very creditably, and did not give way to hysterical fits, but surrendered themselves in a true philosophical spirit, as is their wont, to *kismet*, abiding the course of events in resignation to the will of a higher power. I will not dwell here upon the petty domestic discomforts of the Christian population of this city, or the temporary annoyance caused by the persecution of *tacca-taccas* and the consequent prosecution of the *budmask* element; they are the natural results of rowdiness in every community. But what was more serious and important and involved important issues was the threatened dislocation of trade. European merchants were fighting at long odds a conspiracy, while wire-pullers and their myrmidons were manipulating the strings from behind the scenes, making hay while the sun shone and the scare lasted. The whole country was taken aback at the preposterous announcement in which the Govern-

ment showed such a lamentable foresight, "that true cases of plague had been discovered in the town, and that certain protective measures would be enforced to prevent the spread of the disease." The effect of the public declaration of this notice was tantamount to the bursting of a live shell among a nervous, quaking population such as Indian towns possess, and the result may be more easily imagined than described. The unscrupulous ringleaders of disorder were not slow to take advantage of this state of things, and showed admirable powers of organisation and combination to bring the industries of Calcutta to a deadlock. The employers of labour were compelled to engage workmen at four times their ordinary wages, a proceeding which cut both ways; it entailed heavy initial expense upon those who were powerless to resist the demand, thus setting a premium on lawlessness; while those who did not participate in the gain naturally grew morose, sullen and discontented, thus aggravating the evil. Then again the wealthier natives who did not believe in a real plague spent thousands upon thousands in building hospitals; but no amount of money could manufacture patients to fill the wards of hospitals or persuade people to sham disease. If the Government is not above taking warning from the meanness of its subjects, the experience we have gone through recently should teach it not to interfere with their caste prejudices and happiness without taking into confidence the true leaders and spokesmen of the people themselves."

Yours &c., SUB JANTA.

CALCUTTA; 26 October 1898.

A CASE OF FATAL MALARIAL FEVER, COMPLICATED WITH SEVERE CONGESTION OF THE ABDOMINAL VISCERA.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Assistant Surgeon RAJ KUMAR KUNDRI, L. M. S., requests opinion on the case related by him, under the above heading, in your issue of 16th October. I am glad to see that your journal is the medium for such useful discussions, and I beg to submit my opinion to help your contributor. It is of course very difficult to pronounce on a case simply from such a brief account of it, for many important signs might have been unnoticed or at least unrecorded. But from what I can make out, it appears to strike me that it was *not a case of malaria at all*, but one of Hepatitis running rapidly on to abscess—multiple or simple. The signs therefore pointing to "congestion of abdominal viscera," were really hepatic, and the "dysenteric stools" suggest strongly either, accompanying or associated dysentery, or evacuation of an abscess—it continued for at least five days I notice. This opinion is confirmed by the irregular pyrexia at first the marked and recurrent rigors throughout (no malarial fever has five shiverings a day); while the "remittent fever" type later on, the jaundiced or cachectic appearance, the abdominal symptoms, the red, denuded, (and probably dry) tongue, and the metastatic inflammation of the parotids, all indicate pyæmic infection. It is quite possible to have an enormous liver abscess without external pointing, or without the typical signs and symptoms detailed in ordinary text books. The cessation of shivering on one occasion after quinine should be dis-

garded as anything relating to malaria—we are often led into error by our *post hoc propter hoc* arguments. In all probability the quinine treatment had as little to do with the case as the Ipecac first administered had to do with arresting the "dysentery." I am afraid we are all too ready with our quinine as we are with our brandy—they are, however, both much the same in their action in inhibiting cell growth and dulling nervous energy. The "reddish papillary eruption" was evidently due to the quinine, confirmed by its disappearance with the accidental omission of the dosage five days later. I think we ought to consider well and carefully before administering quinine so freely in so-called "Remittent Fevers"—many of which not being really "malarial" are not amenable to its action, and do more harm than good.

The proper treatment in this case would have been an exploratory aspiration in one or more suspicious regions in the liver, and if pus were discovered, free opening and drainage.

We however are always learning, the very best of us commit errors, some indeed, of the most learned professors have committed the gravest ones—for it is human to err, and we are after all only ordinary human beings. I trust my suggestions may prove of use, for I only give them for what they may be worth.

Yours &c., CAPTAIN, I. M. S.

—:O:—

MADRAS HOSPITAL ASSISTANTS' ON PLAGUE DUTY.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—As I was reading in a Plague Camp, your Articles "How Professors are made in India" and "The Subordination of the Medical Administration of India to the Secretariats" in your issue of the 1st instant, I thought over my own position, and wanted to tell you how we Hospital Assistants on plague duty in the Madras Presidency are placed. They say that "No man can serve two masters" but I am now actually serving under six masters. I receive orders from 6 masters viz., (1) the collector who is the District Board President, (2) the Sub Collector who is the Taluq Board President, (3) the special plague officer (who is a military man but not a medical man), (4) the additional medical officer, a young recruit from England, (with nothing but stinking pride in him) on plague duty, (5) the Tahsildar to whom I am a subordinate as per Section 275 of Civil Medical Code of 1898 and (6) the district medical and sanitary officer. Of the six, three have got the power to fine me on the spot and the other three to recommend me (which is as sure and certain as flogging) for a fine. Thus, I dare not disobey the orders of any of the above. A salt peon or a police constable under me, could be punished *only* by the head of his department, and that too after his explanation is duly recorded and the charges against him duly enquired into.

One of the above said officers orders the Hospital Assistant to issue passports to such and such a class of passengers, whereas another officer orders him not to do so. One countermands the orders of the other and so the poor Hospital Assistant is in a fix. A few Hospital Assistants, unable to bear the worry and annoyance given.

by so many superiors have already resigned their posts ; and those that could not do so, on account of long service, &c. are very much dissatisfied. But, dear Sir, how long are we to be in this state ? As a class we are hard working and patient. But the Government is adding insult to injury. We are kicked about like footballs, from one end of the presidency to the other end, on plague, cholera, famine and such like dangerous duties, with a pay scarcely sufficient to enable us to dress and live like respectable officers. The last straw to break the camel's back is to serve under so many non-professional officers " heaven born " and otherwise, at the same time. The fate of a slave is better than ours.

Besides the above, there are other minor superior officers such as the Manager of the Surgeon General's Office, Head clerks of District Medical and Sanitary Office, District Board Office and Taluq Board Office, Vice-Presidents of District and Taluq Boards (for these pass our bills) &c. &c., to whom we have to make *paja*.

Oh ! Lord when will the day come when the Medical Department will be an independent one !

Can you or any of your numerous readers suggest a remedy for this state of affairs !

Yours &c., HOSPITAL ASSISTANT ON PLAGUE DUTY.

—:—

FALSE REPORTS. AN APPEAL TO THE P. M. O. II. M'S FORCES IN INDIA.

TO THE EDITOR, "INDIAN MEDICAL RECORD"

SIR,—I wish to have your advice as to what I am to do to obtain a hearing from the P. M. O. India, as I know that through simple spite the S. M. O. of the Hospital, the P. M. O. Bombay District, and the P. M. O. Bombay, have one and all, by means of (false) demi-official and private reports been put against me by a certain medical officer, about whom I once wrote to your paper regarding his having kept me in arrest for 3 days. Being unable to frame a charge against me, he released me without having even so much as reported it to the Commandant of the station or P. M. O. After the article appeared in the *Record*, an enquiry was started by the P. M. O. India, and the facts reported, resulting in his being found fault with. Ever since then I have led a miserable life and several times he has so far forgotten himself as to expose his actual feelings by saying "I'll not rest until I have you tried" "I'll place a watch over you to see how often you leave the hospital to attend to private cases" &c., and he has never lost a chance to report me to the S. M. O., very often without a cause.

The last time he had the opportunity of attending the P. M. O. at his inspection visit, the S. M. O. being ill, and the result was that I was very soon after transferred to—although I informed the P. M. O. that I had served in—for two years. Such a thing has never been known, and as nothing official has gone against me, I have every right to know why I am sent to this cruel station a second time. I therefore request you will kindly instruct me how to act or let me know whether I can get assistance from the I. M. Association of which I am a member. I am sure that if the matter is brought

before the P. M. O. India or other higher authority, I will get satisfaction. The chief reason for my removal being desired from—, was that I had the whole run of the private work, yet not once did I neglect my legitimate duties for my private practice. Even if I had committed myself in any way, the proper course would be to place me under arrest, and go through the proper channel, and you may be sure that the M. O. who has acted against me all this time would not have lost the chance had he got it. Trusting dear sir you will help me in this. I have had 15 years' service and have a family of five children.

Yours &c., MILITARY ASSISTANT SURGEON.

(We trust as the P. M. O. of India knows this case, he will very graciously enquire further into it.—ED., I. M. R.)

—:—

CIVIL ASSISTANT SURGEONS ARE NOT SUBORDINATES.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—It is becoming more and more a practice with the various Local Governments and heads of offices generally, to consider the Civil Assistant Surgeons as subordinates and to treat them as such. The Government of India set the example in this matter by being the first to use the word 'subordinate' when dealing with that class of servants in their official correspondence and resolutions, and the other Governments have, as was to be expected, followed suit. The Government of India have gradually by a slow process of obliviation (conscious or unconscious, it matters not which), forgotten altogether that, according to the *Medical Code*, the Civil Assistant Surgeons constitute a distinct service, ranking next to the L. M. S., the Military Assistant Surgeons together with the Hospital Assistants, forming the 'subordinate' service of that code. The head of the medical department whom it behoves to rectify this lapse on the part of the Supreme Government allows the matter to slide, and the Civil Assistant Surgeons, quiet and meek as they are, submitted passively to this fresh humiliation added on to their already full cup of sorrow, although they feel the depreciation keenly and are very sore about it. The bracketing of the three locally recruited medical services under the common designation of "subordinate," however convenient it may be from a government point of view, is decidedly derogatory to the Civil Assistant Surgeons, who as *Gazetted* officers holding *independent* charges, do not come under this denomination. It must also be remembered that the Civil Assistant Surgeons are all University graduates and that as such, they have a recognized academical and social status, as is evidenced by the fact that they are entitled to attendance at Government levees and receptions. It is, however, not yet too late to set matters right, and it is to be hoped that the present head of the Medical Department will take the necessary action to restore the Civil Assistant Surgeons to the position they are entitled to by right, especially now that the Government of India have been pleased to improve their prospects by increasing their pay and rendering them eligible to Civil Surgeoncies.

Yours &c., AN OBSERVER.

SHAMEFUL PROSTITUTION OF MEDICAL MEN TO QUACKS AND QUACKERY.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Herewith I send a cutting, a nice sample of Quack advertising from a native paper. Please take notice of this in your renowned paper if time and opportunity permits :—

FANIAN RAKSHAK.

IT is the latest and most wonderful specific liniment discovered by Dr. S. C. PAUL, graduate of the Calcutta Medical College and practitioner of twenty-five years' standing, for *preventing* miscarriage, for *causing* a safe and easy delivery and for *preserving* infants during nursing. Moreover by lessening the tension of the gravid uterus, it *always* the sympathetic disorders of pregnancy such as nausea, vomiting, acidity, heart burn, flatulence, &c., &c., No family man should be without a bottle of this liniment which is for external application only.

UNSOLICITED TESTIMONIALS.

Dr. G. MANOOK, M. B., (EDIN.) Surgeon, Calcutta, writes :—"I have to report favourably of my trials with your "SANTAN RAKSHAK" I have given your specific a fair trial among all classes. The results have been, I am compelled to say, very wonderful in threatened miscarriage and prolonged labour, where direct interference was impossible. I have no doubt others will be as grateful to you as I am. Please send me one dozen phials more and oblige."

Dr. TAJINI CHARN DUTI, Graduate of the Medical College, Bengal (G. M. C. B.) and retired Assistant-Surgeon, writes :—"I have much pleasure in testifying to the efficacy of your "Santan Rakshak" which is being used by many respectable persons in cases of difficult labor and threatened abortion with satisfactory and unexpected results."

Rupees 2 per phial ; Packing Ans. 4 ; Postage and V P. charges, Ans. 6.

S. C. PAUL, L. M. S.

The Taltollah Medical Hall, 19, Doctor's Lane, Taltollah, Calcutta

Yours &c., M. B. (CALUTTA).

—o.—

SWINDLE THE CIVIL SURGEON.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—Will you or any of your numerous readers kindly express an opinion on the following case.

A Medical Officer of one of the districts in the Provinces was directed by the Collector to examine a lad whose estate is in the Court of wards, as to the lad's physical fitness to go to a boarding school. After the examination was conducted and reported, the doctor suggested a fee of Rs 16 for his services, the Collector demurs to pay and states "he is of opinion that the estate of the person being under the Court of wards, no fee is due to the Civil Surgeon for his medical examination at the instance of the Collector, and asks the Civil Surgeon to state any precedent and point out the rule under which the fee due is Rs. 16."

Is a person whose estate is under the Court of wards entitled to free medical advice, if such be ordered by the Collector, if so, under what authority, bearing in mind that such person is not a Government servant ?

Is not Rs. 16 considered the recognised amount for all such services rendered by a Civil Surgeon ?

It seems to me another case where some one wants to "do" the Doctor.

Yours &c., A SUBSCRIBER.

(The Collector has no authority to order a Medical Officer to attend to on any one but a Government servant. For attendance ordered by the Collector on any other person, the Medical Officer can hold the Collector responsible for his fee and could recover the same from him in a court of law.—Ed. I.M.R.)

MEDICAL ADVERTISING IN LUCKNOW.

TO THE EDITOR, "INDIAN MEDICAL RECORD."

SIR,—With reference to certain remarks in the letter subscribed to by "a British graduate," in your issue of the 16th October 1898, I emphatically deny that I had any hand in the preparation and publication of the notice quoted therein. The writer of the letter and the editor of the *Indian Medical Record* would have done justice to me and a duty to the profession, if they had referred the matter to me before making any unwholesome remark about a professional brother.

Yours &c., MD. A. RAHIM,

LUCKNOW, 30th November, 1898.

(We have great pleasure in publishing Dr. M. A. Rahim's letter. The advertisement referred to was so glaring a one and the use of his name in it was so boldly done, and done for more than two months we learn, before we were apprised of the fact, that Dr. Rahim can blame no one but himself, if he was so slow to put a stop to so unworthy a use of his name.—ED I. M. R.)

Book Reviews.

THE PRINCIPLES AND PRACTICE OF MEDICINE

BY WILLIAM OSLER, M.D., LL.D., F.R.S., F.R.C.P.

Physician in-Chief to the Johns Hopkins Hospital Baltimore ; Professor of Clinical Medicine, University of Pennsylvania ; &c., &c.

(Publisher : YOUNG J. PENTLAND, London and Edinburgh p.p. 1181.)

In every respect the work before us may fairly be characterised as a most admirable text book, which in all its sections maintains its thoroughly practical character as a reliable guide in diagnosis, symptomatology, and treatment. This third edition is brought completely up to date, the articles on Beri-Beri, Dengue, the Bubonic Plague, and other diseases having either been re-written or being entirely new. There can scarcely be any room for doubt that this excellent manual will continue to meet with the cordial reception it undoubtedly deserves on both sides of the Atlantic.

GOOD READING ABOUT MANY BOOKS, SELECTED BY THEIR AUTHORS. THIRD YEAR 1897-98.

(Publisher : T. FISHER UNWIN, London ; p.p. 397.)

THIS publication represents the high-water mark of the advertising ingenuity of our own times, and the enterprising publisher deserves to be warmly congratulated in regard to the compilation turned out. Extracts are given from a number of attractive works on sale by Mr UNWIN, the article or chapter selected being usually preceded by the writer's portrait and followed by his facsimile-autograph in each case. The antique head and tail-pieces, too, add somewhat to the excellent get up of the book.

HARVEY AND DAVIDSON'S SYLLABUS OF MATERIA MEDICA.

BY WILLIAM MARTINDALE, F.L.S., F.R.S., &c.

(Publishers : H. K. LEWIS, London ; p.p. 64, Price 1s.)

THE present is the tenth edition of this popular little pocket syllabus which is extensively used by students at home. The arrangement followed in the Tables &c., it contains, is certain to prove exceedingly valuable to all of those who use it.

Government Medical Gazettes.

GOVERNMENT OF INDIA.

Surgn.-Genl James Cleghorn, M.D., C.S.I., Bengal, retires from 25th Oct. 1898.

Lieut.-Col. James Joseph Moran, M.D., Madras, retires from 10th Oct. 1891.

Capt. William Carr Sprague, M.D., Bombay, resigned the service, 29th Oct. 1898.

Asst. Surgn. J. A. Lobo, Civil Dispy., Bushire, furlough for twelve months, from 6th Nov. 1898.

Asst. Surgn. J. Fraser, to Civil Dispy., Bushire, from 6th Nov. 1898.

To be Surgn.-Col.

Brig. Surgn.-Lieut.-Col. David Sinclair, Madras, 12th Feb. 1896.

Surgn. Lt.-Cols to be, Brig. Surgn.-Lt.-Col.

MADRAS.—Henry FitzLawrence Plankett, French Eamon-de-White 31st Oct. 1897

William Richard Browne, M.D., 1st March 1898.

Arthur Henry Leapingwell, 1st March 1898.

Hazlett Allison, M.D., 30th June 1898.

Thomas James Hackett Wilkins, 14th July 1898.

BOMBAY.—John Philip Greany, M.D., 9th June 1898.

Surgn. Lieuts. to be Surgn. Capts.

BENGAL.—John Stephenson, Frank Needham Windsor Walter Barrie Turnbull, Ernest Edwin Waters, Asher Leventon, Philip Francis Chapman.

MADRAS.—Frederick Linton Blenkinsop, Edmund Moritz Illington, Thomas Edgar Watson, Charles George Webster.

BOMBAY.—Alfred Hooton, Arthur Frederick William King, Robert Fraser Standage, Andrew Armstrong Gibbs, Henry Alfred Forbes Knapton.

BENGAL GOVERNMENT.

Capt. A. F. Stevens, I.M.S., to have med. charge civil station of Dinapore, from 11th Nov. 1898.

Asst. Surgn. F. J. Daley, Medl. Officer, Plague Observation Camp, Khurda Road Stn. privilege leave from 6th to 30th Nov. 1898.

Dr U. C. Mukerjee, Civil Medl. Officer of Malda, to Pabna. Kumar Bhobendra Narayan, Civil Medl. Officer of Pabna, to Malda.

Dr J. A. Fink, Offg. Civil Medical Officer of Purnea, to act as Civil Medl. Officer of Malda.

The late Dr. P. M. Gupta, Civil Medl. Officer of Faridpur, was on privilege leave from 13th to 24th Nov. 1898.

Asst. Surgn. Kasi Nath Ghosh to have med. charge, Civil Stn. of Faridpur.

To be Senior Asst. Surgn. with hon. rank of Capt. Richard Michael Blaker, 17th Feb. 1898.

To be Senr. Asst. Surgn. with hon. rank of Surgn. Lieut. Isaac Burnett, 17th Feb. 1898.

PUNJAB GOVERNMENT.

Lieut.-Col. A. Denno, M.D., I.M.S. (Bengal), to officiate as Insp.-Genl. of Civil Hosps., Punjab.

Hosp. Asst. Nuckal Bain resumed charge, 5th Division, Chenab Canal, 3rd Nov. 1898.

Hosp. Asst. Narsingh Das, Alipur Dispy., Muzaffargarh Dist., passed the English Qual. Exam. entitled to the higher rate of the pay of his grade from 1st Oct. 1898.

Hosp. Asst. Sham Lal, Police Hosp. Dera Ghazi Khan, having passed the English Qual. exam. entitled to the higher rate of the pay of his grade from 15th Nov. 1898.

Hosp. Asst. Ibrar Hussain on special plague duty Hoshiarpur Dist. from 17th Feb. to 15th July 1898.

Hosp. Asst. Ganesh Das resumed charge Anandpur Dispy., Hoshiarpur Dist., 13th Nov. 1898.

Asst. Surgn. Miran Baksh Utard, to do genl. duty, Maghalana Dispy. Jhang Dist., 11th Nov. 1898.

Hosp. Asst. Sunder Singh, Police Hosp., Umballa, one month's privilege leave, from 6th Nov. 1898.

BOMBAY GOVERNMENT.

The following transfers are sanctioned:—

Asst. Surgn. Arthur Victor Marshall King from House of Correction, Common Prison, Bombay, to Bai Motilal and Sir D. M. Petit Hospitals, Bombay.

Hosp. Asst.—Bhawaniprasad Bhagwanlal Kaweshwar, from C. J. Ophthalmic Hosp. Bombay, to House of Correc-

tion and Byculla Schools, Bombay, 23rd Nov. 1898, Amru Govind, to Genl. duty, Bombay, from 6th Sept. 1898, Ramrao Shamrao, from Civil Hosp. Karwar, to Observation and Segregation Camps Tadril, Kanare, 18th Sept. 1898, Balwant Succaram Vaidya, from Genl. duty, Bombay, to Dispy. Bhatkal, Balkrishna Vitthal Chaud, from Civil Hosp. Satara, to Plague duty, from 18th Oct. 1898, Vishan Balwant Bhikie, from Civil Hosp. Satara, to Plague duty, from 13th Oct. 1898, Chhunilal Parbhudas, from Dispy. Halol, to Plague duty, Anand, Ambala Motilal, from Dispy. Bavi, to Plague duty, Ankleswar, Mahomedusuff Dadamiya, from Dispy. Amod, to Plague duty, Ankleswar, Pasmal Wadhmal, from Dispy., Mitti, to Central Prison Hosp. Hyderabad, 8th Sept. 1898.

CENTRAL PROVINCES GOVERNMENT.

Hosp. Assts. Girdhari Lal and Ramasbraya Jagannath Dube, doing duty under Civil Surgn. Nagpur, are deputed on Plague duty at Hinganghat, Wardha Dist.

Hosp. Asst. Balwant Lakhman, Police Hosp. Nagpur, to Mowar Branch Dispy., Nagpur dist.

Hosp. Asst. Vishnu Hari Date to Police Hosp., Nagpur.

Hosp. Asst. Kalamam, doing duty under Civil Surgn. of Raipur, to do duty under Civil Surgn. of Nagpur.

N.-W. P. AND OUDH GOVERNMENT.

The undermentioned Civil Hosp. Assts. of the Provincial Staff of the N.-W. P. and Oudh, having passed their Septil. Exam., are promoted to the next higher grade.

Nazir Ali Khan, Wazir Uddin, Enayet Ali, Jagan Nath, Abdul Qadir, Joti Parshad, Badi Uddin, Muhammad Hamid, Sadiq Ali, Qamr Uddin, Rahim Baksh, Sharf Uddin, Cheda Lal, Gobind Ram, Muhammad Azimuddin, Zia-ul-Hasan, Abdul Rahman Khan, Samji Lal, and Muhammad Akber.

BURMA GOVERNMENT.

Major A. R. P. Russell, I.M.S., made over, Capt. J. W. Wolfe, I.M.S. assumed charge, Civil Surgery, of Myingyan dist., 21st Nov. 1898.

Hosp. Asst. Shaik Kurlan Ally, three months privilege leave, 23rd Nov. 1898.

Hosp. Asst. H. C. Banerjee, relinquished charge, Civil Dispy. Maubin, Tongwa dist. 21st Nov. 1898.

Hosp. Asst. K. Kanare assumed charge, Civil Dispy. Maubin, Tongwa dist. 21st Nov. 1898.

Hosp. Asst. Jai Lal assumed charge, Civil Hosp., Prome, 23rd Nov. 1898.

Hosp. Asst. Shaik Kurlan Ally made over, and Hosp. Asst. Jai Lal assumed charge, Jail Hosp. Prome, 23d Nov. 1898.

Hosp. Asst. F. A. Jeyceala Rao assumed charge Civil Hosp. Pantana, Myaingmya dist. 16th Nov. 1898.

ASSAM GOVERNMENT.

Hosp. Asst. Krishna Prasad Sen, a Supery. Lakhimpur dist. to med. charge Bomjur Mily. Police outpost, from 18th Oct. 1898.

Hosp. Asst. Prabhat Chakravarti, Borjoha Dispy., Nowgong dist., to Dobaka Dispy. from 15th Oct. 1898.

Hosp. Asst. Rajendra Prasad Das, Dobaka Dispy., Nowgong dist. to Borjoha Dispy. from 31st Oct. 1898.

Hosp. Asst. Mahendra Chandra Chakravarti, a Supery, Lushai Hills dist. to Nylhet dist., a supery. for duty under Civil Surgn. from 11th Nov. 1898.

DOMESTIC OCCURRENCES.

The charge for inserting a Domestic Occurrence is Rs. 1 for subscribers and Rs. 2 for non-subscribers, which should be forwarded in stamps with the announcement.

BIRTH.

SHORT-EVERS.—On the 17th November, at Madras, Mrs. Ida Bowie Evers, L.R.C.P. and S. E. D., the wife of Assistant Surgeon J. Short-Evers, Assistant to the District Medical and Sanitary Officer, Palamcottah, of a daughter.

DEATH.

WILSON.—On the 4th December, 1898, at Shajehanpur Dorothy Barnett, the only child of Major and Mrs. J. B. Wilson, B.A.M.C., aged 1 year and 2 months.

NOTICES TO CORRESPONDENTS.

Bella M. B. (Eden Hospital).—We repeat your query "who gave little Cecil the eye." Cissy knows, ask her.

Medical College Hosp. student writes:—"Professor Murray thinks of inserting some new splints for the treatment of fracture of the thigh. They will be an improvement on Liston's." We expect also to hear of some startling suggestions on trephining.

L. A. L. (General Hospital).—We are strongly of opinion that blood for purposes of bacteriological examination should be taken from any portion of the surface of the body. To draw blood from the spleen is to risk the health and even the life of the patient, and it is a serious responsibility for a hospital surgeon to advise such an experiment. To ask an ignorant mother (ignorant of course in medical matters) whether she has any objection to allowing blood to be drawn from her child's spleen for such examination, and to obtain her sanction, is but poor justification even in the eyes of the law. The experiment is not unattended with danger and the hospital surgeons know this and herein lies the criminality.

You state that Dr. Ronald Ross performed this experiment. Ask Dr. Ross if he would perform a similar experiment on his own child. The curse of experimenters is that they are often inhumanly cruel and heartless.

S. K. C. (Medal Katti).—You will find the treatment of eczema fully discussed in the editorial columns of back numbers of the *Record*, look them up.

Secretary, Calcutta Medical School. We note your letter of 10th December, in which you state that the present roll of your school shows 421 students on your lists.

Lt. Col. A. M. C. writes:—"By the way that was a very offensive "skit" you published as a letter from an Assistant Surgeon in the 16th November issue, it had no *raison d'être*, as it brought forward no grievance."

"It is not wise to encourage men in turning their superior officers into ridicule and I don't think the letter reflects well upon the man who wrote it. I am sure it would be very offensive to some of the R. A. M. C. officers."

We are sorry this "skit" appeared. However we trust our correspondent will take this criticism to heart and refrain from being offensive unnecessarily. We apologise for our share of blame in the publication.

S. A. (Rurki).—The review of your excellent book on "Children's Diseases in India" appeared in the *Record* of October, 1891.

N. C. C. (30 Brindaban Chundera Lane, Calcutta).—We shall not interfere any further with Kviraj N. N. Sen Gupta, unless he continues to be guilty of further unprofessional conduct. Your letter regarding him is filed.

H. K. S.—If one orange sells for one pice, two will cost two pice. It would be unfair to expect two for one pice. This is the principle on which the *Record* prices have been fixed. No one has any right to grumble about them.

Stationery Office, Calcutta.—Mr H B Beames, Superintendent of Stationery (Newspaper and Periodical Branch) writes under date, 3rd November, 1898, No. 1220. "With reference to your letter dated 20th ultimo, asking for information as to the amount of the subsidy paid by the Bengal Government to the *Indian Medical Gazette*, I regret to say that the information asked for cannot be given." This is the secret machinery by which the Bengal

Government defrauds the taxpayers, and this is the stealthy system by which it stops enquiry and gags the public press as to its iniquitous doings. This is what is styled Government in India. We call it high-handed tyranny.

A. K. C. (Naihati).—Your case is one for the lawyers of the Indian Medical Association, when you have had an expression of legal opinion thereon, the Council will be in a position to help you.

Calcutta Advertisers, S. O. M. writes:—"Here are two advertisements cut from the *Statesman*:—"Dr. S. B. Mitra, B.Sc. M.B. (London), has removed to 36, Wellington Street, Calcutta. Hours of consultation at his residence, from 7 to 8 A.M. (free), and 4 to 5-30 P.M. (charged)."

"Miss Maud S. Martin, M.D., late House Surgeon, Calcutta Dufferin Hospital, having returned from England, will resume private practice. Address: 42, Dhurumtollah Street."

Local Practitioner (Hyderabad, Sindh), writes:—"I beg to inform you that the private practice of the medical practitioners here is quite spoiled by the Veterinary Surgeon employed by the Local Board. I am at a loss to understand how he, who is only a "vet," can undertake to treat human beings, but he actually does so, and all but monopolises the local practice, the rest being swallowed up by the Civil Surgeon and his subordinates, the latter of whom maintain their own dispensaries. We local practitioners are thus being deprived of all practice. Is there no remedy for this state of affairs?"

M. S. (Bombay).—We have expressed our opinion fully and frankly about the bogus diploma selling syndicate of Chicago. It had better stop its objectionable practice in Bombay or the Government will interfere through the medium of a police prosecution.

Medical Affairs (Simla).—Surgeon-General Harvey is a genius, but we question whether he is willing to burden his mind or body with a consideration of the medical grievances of India, as they concern the profession or medical science. He has a great opportunity of doing good for India and the profession, but whether he will avail himself of these opportunities in the masterful style which he is so thoroughly capable of, is quite another matter, we can only hope he will.

S. T. (Hyderabad) writes:—"Having read in your journal of November 16th, an article on the subject of "Abortion by Quinine" &c. I venture to write and ask your advice. My wife has been suffering from remittent fever for some time, and I have tried all the ordinary remedies without any effect, but have refrained from giving phenacetin, antifebrin, &c, being aware of their tendency to cause abortion. Will you or any of your numerous readers kindly inform me as to what might safely be given, during the fever, as well as after it?"

M. J. V. (Shahdarpur).—Writes:—"Will you or any of your numerous readers kindly suggest a treatment for the case of a female child aged 2½ years suffering from prolapsus ani. The ani prolapses about 3 or 4 times daily and is easily reducible. Is there no remedy to stop its prolapsing. She suffers from 3 or 4 loose motions a day, but no dyspepsia. Various astringents, antidyseptic remedies have been tried internally and also astringent applications, such as ointments and suppositories, have been tried but to no effect. There is no history of worms. Can any of my brother readers of the *Record* suggest any thing to cure it and oblige."

W. C. McM. (Jask).—You have done wisely and well. We wish you success.
